Index ......................................................................................... 711
# Table of Contents

## Introduction
- Licensing ................................................................. 2
- Who This Book Is For .................................................. 3
- What This Book Contains ........................................... 4
- Conventions Used in This Book ................................. 5

## Part I Installing and Configuration

### 1 Installing Ubuntu
- Before You Begin the Installation .................................... 9
  - Researching Your Hardware Specifications ......................... 10
  - Installation Options .................................................... 10
  - Planning Partition Strategies ........................................ 10
  - The Boot Loader ......................................................... 11
  - Installing from CD or DVD .......................................... 11
- Step-by-Step Installation ................................................ 11
  - Installing ........................................................................ 12
  - First Update ................................................................... 15
  - Wubi—The Easy Installer for Windows ............................... 16
- Shutting Down ............................................................... 17
- Reference ......................................................................... 18

### 2 Post-Installation Configuration
- Troubleshooting Post-Installation Configuration Problems ....... 19
- The sudo Command ......................................................... 21
- Software Update ......................................................... 21
- Configuring Software Repositories .................................... 24
- Installing Graphics Drivers ............................................. 27
- Changing Ubuntu’s Look and Feel ..................................... 28
  - Changing the Desktop Background ..................................... 28
  - Changing Colors ......................................................... 29
  - Modifying System Fonts .................................................. 31
  - Visual Effects .............................................................. 31
- Preferred Behaviors ....................................................... 32
- Input Devices .................................................................. 33
  - Keyboard Shortcuts ....................................................... 33
3 Working with GNOME

The GNOME Desktop Environment .................................................. 41
Eye Candy for the Masses ................................................................ 42
Basic X Concepts ........................................................................... 43
Using X ........................................................................................ 44
- Elements of the \texttt{xorg.conf} File ........................................... 45
- Configuring X ............................................................................ 46
Starting X ..................................................................................... 47
- Using a Display Manager ........................................................ 48
- Configuring Your Login Screen ................................................. 49
- Changing Window Managers ................................................... 50
Reference ...................................................................................... 51

4 Command Line Quickstart

What Is the Command Line? ........................................................... 52
Navigating Through the File System .......................................... 53
Managing Files with the Shell ................................................... 54
Working with Compressed Files ................................................ 55
Essential Commands from the /bin and /sbin Directories .............. 56
Using and Editing Files in the /etc Directory ............................... 57
Using the Contents of the /home Directory — with the Kernel ...... 58
Using the Contents of the /proc Directory to Interact .......... 59
- Working with Shared Data in the /usr Directory .................. 60
- Temporary File Storage in the /tmp Directory ....................... 61
- Accessing Variable Data Files in the /var Directory .......... 62
Logging In to and Working with Linux .............................................. 63
- Text-Based Console Login ...................................................... 64
- Logging Out .......................................................................... 65
- Logging in and Out from a Remote Computer ...................... 66
- Using Environment Variables ............................................... 67
Using the Text Editors ................................................................. 76
  Working with vi ................................................................. 76
  Working with emacs ............................................................ 77
Working with Permissions ......................................................... 79
  Assigning Permissions .......................................................... 80
  Directory Permissions .......................................................... 81
Understanding Set User ID and Set Group ID Permissions ............. 83
Working as Root ............................................................................ 84
  Creating Users ........................................................................ 85
  Deleting Users ...................................................................... 86
Shutting Down the System ......................................................... 87
Rebooting the System ............................................................... 88
Reading Documentation ............................................................ 88
  Using Apropos ...................................................................... 88
  Using Man Pages .................................................................... 89
Reference .................................................................................... 90

Part II  Desktop Ubuntu

5  On the Internet ................................................................. 91
  Getting Started with Firefox ..................................................... 92
  Checking Out Google Chrome and Chromium .......................... 93
Choosing an Email Client ........................................................... 94
  Evolution .............................................................................. 95
  Mozilla Thunderbird ............................................................. 96
  Other Mail Clients .................................................................. 97
RSS Readers .............................................................................. 97
  Firefox .................................................................................. 97
  Liferea .................................................................................. 98
Instant Messaging and Video Conferencing with Empathy .......... 98
Internet Relay Chat ................................................................... 99
Usenet Newsgroups ................................................................... 102
Ubuntu One Cloud Storage ...................................................... 103
Reference .................................................................................... 104

6  Productivity Applications .................................................. 105
  Introducing OpenOffice.org ................................................... 106
    Configuring OpenOffice.org ............................................... 108
    Working with OpenOffice.org Writer ................................. 109
    Working with OpenOffice.org Calc ...................................... 112
Office Suites for Ubuntu ................................................................. 116
  Working with Gnome Office ....................................................... 117
  Working with KOffice ................................................................. 120
Productivity Applications Written for Microsoft Windows ............. 122
Reference .................................................................................... 123

7 Multimedia Applications .............................................................. 125
  Sound and Music ........................................................................ 125
    Sound Cards ........................................................................... 126
    Adjusting Volume ................................................................... 127
    Sound Formats ....................................................................... 128
    Listening to Music .................................................................. 129
    Buying Music in the Ubuntu One Music Store ......................... 132
  Graphics Manipulation ............................................................... 132
    The GNU Image Manipulation Program .................................. 133
    Using Scanners in Ubuntu ....................................................... 135
    Working with Graphics Formats ............................................ 136
    Capturing Screen Images ....................................................... 138
  Using Digital Cameras with Ubuntu ............................................ 138
    Handheld Digital Cameras ...................................................... 138
    Using Shotwell Photo Manager .............................................. 139
  Burning CDs and DVDs in Ubuntu ............................................. 139
    Creating CDs and DVDs with Brasero ...................................... 140
    Creating CDs from the Command Line .................................... 141
    Creating DVDs from the Command Line .................................. 142
  Viewing Video ........................................................................... 144
    TV and Video Hardware .......................................................... 144
    Video Formats ....................................................................... 146
    Viewing Video in Linux .......................................................... 146
    Personal Video Recorders ....................................................... 147
    Video Editing ......................................................................... 148
Reference .................................................................................... 148

8 Other Ubuntu Desktops ................................................................. 149
  Desktop Environment ............................................................... 149
  KDE and Kubuntu ..................................................................... 150
  Xfce and Xubuntu .................................................................... 152
  Ubuntu Netbook Edition .......................................................... 153
  LXDE and Lubuntu .................................................................... 155
Reference .................................................................................... 156

11 Automating Tasks

Running Services at Bootup ............................................................ 198
Beginning the Boot Loading Process ................................................ 198
  Loading the Linux Kernel ....................................................... 199
  System Services and Runlevels ................................................ 200
  Runlevel Definitions ............................................................. 200
  Booting into the Default Runlevel ........................................... 201
Understanding init Scripts and the Final Stage of Initialization .... 201
Controlling Services at Boot with Administrative Tools ............... 202
Changing Runlevels .............................................................. 203
Troubleshooting Runlevel Problems ......................................... 204
Starting and Stopping Services Manually .......................................... 205
Using Upstart .............................................................................. 205
Basic Shell Control ....................................................................... 211
  The Shell Command Line ...................................................... 212
  Shell Pattern-Matching Support............................................... 214
Redirecting Input and Output ................................................. 214
  Piping Data ......................................................................... 215
  Background Processing .......................................................... 216
Writing and Executing a Shell Script ................................................ 216
  Running the New Shell Program ............................................. 218
  Storing Shell Scripts for Systemwide Access ................................ 219
  Interpreting Shell Scripts Through Specific Shells ....................... 219
Using Variables in Shell Scripts ............................................... 220
Assigning a Value to a Variable ............................................... 221
  Accessing Variable Values....................................................... 222
Positional Parameters ............................................................ 222
  A Simple Example of a Positional Parameter .............................. 222
Using Positional Parameters to Access and Retrieve Variables from the Command Line 223
Using a Simple Script to Automate Tasks ..................................... 224
Built-In Variables .................................................................. 226
Special Characters ................................................................... 226
Using Double Quotes to Resolve Variables in Strings with Embedded Spaces 227
Using Single Quotes to Maintain Unexpanded Variables.................. 228
Using the Backslash as an Escape Character .................................. 229
Using the Backtick to Replace a String with Output ....................... 229
Comparison of Expressions in pdksh and bash .......................... 230
Comparing Expressions with tcsh ............................................ 235
## Using Backup Software

- tar: The Most Basic Backup Tool .............................................. 276
- The GNOME File Roller ......................................................... 278
- The KDE ark Archiving Tool ................................................... 279
- Using the Amanda Backup Application..................................... 279
- Alternative Backup Software ................................................... 280

## Copying Files

- Copying Files Using `tar` ......................................................... 281
- Compressing, Encrypting, and Sending `tar` Streams ................. 282
- Copying Files Using `cp` .......................................................... 282
- Copying Files Using `mc` .......................................................... 283
- Using `rsync` ......................................................................... 284

## System Rescue

- The Ubuntu Rescue Disc ........................................................ 285
- Restoring the GRUB2 Boot Loader ........................................... 285
- Saving Files from a Non-Booting Hard Drive ............................. 286

## Reference

- 14 Networking 289

### Networking

- Laying the Foundation: The localhost Interface ................................. 290
  - Checking for the Availability of the Loopback Interface ................. 290
  - Configuring the Loopback Interface Manually .............................. 290
- Networking with TCP/IP ................................................................ 293
  - TCP/IP Addressing ................................................................ 294
  - Using IP Masquerading in Ubuntu ........................................... 296
  - Ports ................................................................................... 296
- Network Organization ................................................................... 297
  - Subnetting ........................................................................... 297
  - Subnet Masks ....................................................................... 298
  - Broadcast, Unicast, and Multicast Addressing ............................ 298
- Hardware Devices for Networking ................................................... 299
  - Network Interface Cards ........................................................ 299
  - Network Cable ..................................................................... 301
  - Hubs and Switches .................................................................. 302
  - Routers and Bridges ............................................................... 303
  - Initializing New Network Hardware ......................................... 303
- Using Network Configuration Tools ................................................. 305
  - Command-Line Network Interface Configuration ....................... 306
  - `/bin/netstat` ......................................................................... 310
  - Network Configuration Files ................................................... 311
  - Using Graphical Configuration Tools ....................................... 313
Contents

Dynamic Host Configuration Protocol ............................................. 314
How DHCP Works ................................................................ 315
Activating DHCP at Installation and Boot Time ......................... 316
DHCP Software Installation and Configuration .......................... 317
Using DHCP to Configure Network Hosts ................................. 318
Other Uses for DHCP ............................................................ 320
Wireless Networking ..................................................................... 321
Support for Wireless Networking in Ubuntu .............................. 321
Advantages of Wireless Networking ......................................... 322
Choosing from Among Available Wireless Protocols 323
Beyond the Network and onto the Internet ...................................... 324
Common Configuration Information .............................................. 324
Configuring Digital Subscriber Line Access ............................... 325
Understanding Point-to-Point Protocol over Ethernet 326
Configuring a PPPoE Connection Manually 327
Configuring Dial-Up Internet Access ........................................... 328
Troubleshooting Connection Problems ........................................... 329
Reference .................................................................................... 330

15 Remote Access with SSH and Telnet 331
Setting Up a Telnet Server .............................................................. 331
Telnet Versus SSH ......................................................................... 333
Setting Up an SSH Server ............................................................... 333
SSH Tools .................................................................................... 334
Using scp to Copy Individual Files Between Machines ............... 334
Using sftp to Copy Many Files Between Machines ....................... 335
Using ssh-keygen to Enable Key-Based Logins ............................ 335
Virtual Network Computing (VNC) ................................................. 337
Reference .................................................................................... 340

Part IV Ubuntu as a Server

16 File and Print 341
Using the Network File System ....................................................... 342
Installing and Starting or Stopping NFS ........................................ 342
NFS Server Configuration ............................................................ 342
NFS Client Configuration ............................................................ 344
Putting Samba to Work ................................................................. 345
Manually Configuring Samba with /etc/samba/smb.conf ............. 346
Testing Samba with the testparm Command ............................... 349
Starting, Stopping, and Restarting the smbd Daemon ................... 350
Mounting Samba Shares ............................................................... 351
Configuring Samba Using SWAT .................................................. 352

Download from www.eBookTM.com
Network and Remote Printing with Ubuntu ...................................... 356
  Creating Network Printers ...................................................... 356
  Using the Common UNIX Printing System GUI ........................ 358
  Avoiding Printer Support Problems .......................................... 360
Reference .................................................................................... 362

17 Apache Web Server Management ............................................. 363
  About the Apache Web Server ......................................................... 363
  Installing the Apache Server ........................................................... 365
    Installing from the Ubuntu repositories .................................... 365
    Building the Source Yourself ................................................... 366
  Starting and Stopping Apache ......................................................... 369
    Starting the Apache Server Manually ........................................ 369
    Using /etc/init.d/apache2 ..................................................... 370
  Runtime Server Configuration Settings ............................................. 371
    Runtime Configuration Directives ........................................... 372
    Editing apache2.conf ............................................................. 372
    Apache Multiprocessing Modules ............................................ 375
    Using .htaccess Configuration Files ........................................... 375
  File System Authentication and Access Control ................................. 377
    Restricting Access with allow and deny .................................... 378
    Authentication ..................................................................... 379
    Final Words on Access Control ................................................ 381
  Apache Modules ........................................................................... 382
    mod_access ........................................................................... 383
    mod_alias ............................................................................. 383
    mod_asis .............................................................................. 383
    mod_auth .............................................................................. 384
    mod_auth_anon ...................................................................... 384
    mod_auth_dbm ........................................................................ 384
    mod_auth_digest .................................................................... 384
    mod_autoindex ...................................................................... 385
    mod_cgi ............................................................................... 385
    mod_dir and mod_env ............................................................. 385
    mod.expires .......................................................................... 385
    mod.headers ......................................................................... 385
    mod.include .......................................................................... 386
    mod.info and mod_log_config .................................................. 386
    mod_mime and mod_mime_magic .................................................. 386
    mod_negotiation ..................................................................... 386
    mod_proxy ............................................................................ 386
    mod_rewrite ........................................................................... 386
    mod_setenvif ......................................................................... 387

About the Authors

Matthew Helmke is an active member of the Ubuntu community. He is an administrator for the Ubuntu Forums (www.ubuntuforums.org) and chairman of the Ubuntu Forums Council. He coauthored the most recent editions of The Official Ubuntu Book. Matthew first used UNIX in 1987 while studying LISP on a Vax in a summer program at Northern Arizona University. He has run a business using only free and open-source software, has consulted, and is currently working on a master’s degree in Information Resources and Library Science at the University of Arizona while working as the Senior Technical Documentation Specialist for iPlant Collaborative (www.iplantcollaborative.org). The iPlant Collaborative project, among other things, is creating an advanced bioinformatics cyberinfrastructure to help biologists solve grand challenges in the plant sciences. You can find out more about Matthew at matthewhelmke.com or drop him a line with errata or suggestions at matthew@matthewhelmke.com.

Andrew Hudson is a freelance journalist who specializes in writing about Linux. He has significant experience in Red Hat and Debian-based Linux distributions and deployments and can often be found sitting at his keyboard tweaking various settings and config files just for the hell of it. He lives in Wiltshire, which is a county of England, along with his wife, Bernice, and their son, John. Andrew does not like Emacs. He can be reached at andy.hudson@gmail.com.

Paul Hudson is a recognized expert in open-source technologies. He is also a professional developer and full-time journalist for Future Publishing. His articles have appeared in Mac Format, PC Answers, PC Format, PC Plus, and Linux Format. Paul is passionate about free software in all its forms and uses a mix of Linux and BSD to power his desktops and servers. Paul likes Emacs. Paul can be contacted through http://hudzilla.org.
Dedication

To Heather, Saralyn, Sedona, and Philip—the most amazing family a guy could hope for, to my grandfather for always believing in me and teaching me to believe in myself, and to my friends in the Ubuntu community, especially those with whom I work most closely in the Ubuntu Forums.

—Matthew Helmke

Acknowledgments

I am solely responsible for this edition of Ubuntu Unleashed, but freely acknowledge that I am standing on the shoulders of giants. I want to express my gratitude to Andrew Hudson and Paul Hudson for the solid foundation that past editions of the book (up to Ubuntu Unleashed 2008) provided to this update. Thanks to Ryan Troy for helping with the 2010 edition. Thank you to the many people who helped with technical edits and advice, especially Andrew Lenards, Robert Day, John Wregglesworth, Jeremy Foshee, and several developers who wanted to remain anonymous. A huge debt of gratitude is owed to the Ubuntu community, Canonical, and Mark Shuttleworth for inviting me to participate in the community, including my role in the forums, a turn on the EMEA membership board, and two Ubuntu Developer Summits. Thanks to the Ubuntu All Stars for the chance to jam with you on guitar. Thank you to the entire Ubuntu community for your labor of love to create this wonderful operating system. Finally, thanks to my colleagues at Pearson, especially Debra Williams Cauley, for the trust placed in me and the opportunity to collaborate on projects like this one.

—Matthew Helmke
We Want to Hear from You!

As the reader of this book, you are our most important critic and commentator. We value your opinion and want to know what we’re doing right, what we could do better, what areas you’d like to see us publish in, and any other words of wisdom you’re willing to pass our way.

You can email directly to let us know what you did or didn’t like about this book—as well as what we can do to make our books stronger.

Please note that we cannot help you with technical problems related to the topic of this book, and that due to the volume of mail we received, we might not be able to reply to every message.

When you write, please be sure to include this book’s title and author as well as your name and email address. We will carefully review your comments and share them with the author and editors who worked on the book.

Email: opensource@samspublishing.com

Mail: Debra Williams Cauley
Sams Publishing
800 East 96th Street
Indianapolis, IN 46240 USA

We are pleased to present the 2011 edition of *Ubuntu Unleashed*. Ubuntu is a Linux-based computer operating system that has taken the world by storm. From its humble beginning in 2004, Ubuntu has risen to be the vanguard of desktop Linux, as well as a popular choice for servers.

Ubuntu descends from one of the oldest and most revered Linux distributions, Debian. Debian is assembled by a team of talented volunteers, is one of the most stable and customizable distributions of Linux, and is well respected for its quality and technological prowess. It is, however, an operating system for geeks; the bar for entry into the Debian realm is set high, and its user base tends to be highly proficient and expects new users to learn the ropes before joining in. That is both appropriate and okay.

What Ubuntu has done is leverage the quality of Debian to create an operating system that ordinary people can use. That doesn’t mean that Ubuntu users are not technologically proficient, just that they do not have to be. In fact, many talented and respected software developers love Ubuntu because it allows them to concentrate on their specific interests instead of the details of the operating system. This book is for these people and for those who aspire to joining their ranks.

If you are new to Linux, you have made a great decision by choosing this book. Sams Publishing's *Unleashed* books offer an in-depth look at their subjects, taking in both beginner and advanced users and moving them to a new level of knowledge and expertise. Ubuntu is a fast-changing distribution that has an updated release twice a year. We have tracked the development of Ubuntu from early on to make sure that the information in this book mirrors closely the
development of the distribution. A full copy of Ubuntu is included on the enclosed disc, and it is possible for you to install Ubuntu from that disc in less than an hour!

Do not let the reputation of Linux discourage you, however. Many people who have heard of Linux think that it is found only on servers, looking after websites and email. Nothing could be further from the truth. Distributions like Ubuntu are making huge inroads in to the desktop market. Corporations are realizing the benefits of running a stable and powerful operating system that is easy to maintain and easy to secure. The best part is that as Linux distributions make improvements, the majority of those improvements are shared freely, allowing you to benefit from the additions and refinements made by one distribution, such as Red Hat, while continuing to use a different distribution, such as Ubuntu, which also shares its improvements. You can put Ubuntu to work today and be assured of a great user experience. Feel free to make as many copies of the software as you want; Ubuntu is freely and legally distributable all over the world—no copyright lawyers are going to pound on your door.

We would like to take a moment to introduce a concept called “The Three Levels of Listening” from Alistair Cockburn’s *Agile Software Development*, published by Addison Wesley. These describe how a person learns and masters a technique. We all start at the first stage and progress from there. Few reach the last stage, but those who do are incredibly effective and efficient. People aiming for this stage are the very ones for whom we intend this book.

- **Following**—The stage where the learner looks for one very detailed process that works and sticks to it to accomplish a task.

- **Detaching**—The stage where the learner feels comfortable with one method and begins to learn other ways to accomplish the same task.

- **Fluent**—The stage where the learner has experience with or understanding of many methods and doesn’t think of any of them in particular while doing a task.

A myriad of books focus on the first set of users. This is not one of them. It is our goal in *Ubuntu Unleashed* to write just enough to be sufficient to get you from where you are to where you want or need to be. This is not a book for newcomers who want or need every step outlined in detail, although we do that occasionally. Ubuntu Unleashed is intended for intermediate and advanced users, or those who wish to become one. Our goal is to give you a nudge in the right direction, to help you enter the higher stages by exposing you to as many different tools and ideas as possible; we want to give you some thoughts and methods to consider, and spur you on to seek out more.

**Licensing**

Software licensing is an important issue for all computer users and can entail moral, legal, and financial considerations. Many consumers think that purchasing a copy of a commercial or proprietary operating system, productivity application, utility, or game conveys ownership, but this is not true. In the majority of cases, the *end user license agreement*
(EULA) included with a commercial software package states that you have paid only for the right to use the software according to specific terms. This generally means you may not examine, make copies, share, resell, or transfer ownership of the software package. More onerous software licenses enforce terms that preclude you from distributing or publishing comparative performance reviews of the software. Even more insidious licensing schemes (and supporting legislation, especially in the United States) contain provisions allowing onsite auditing of the software’s use!

This is not the case with the software included with this book. You are entirely free to make copies, share copies, and install the software on as many computers as you want—we encourage you to purchase additional copies of this book to give as gifts, however. Be sure to read the README file on the disc included with this book for important information regarding the included software and disk contents. After you install Ubuntu, go to www.gnu.org/licenses/gpl.html to find a copy of the GNU GPL. You will see that the GPL provides unrestricted freedom to use, duplicate, share, study, modify, improve, and even sell the software.

You can put your copy of Ubuntu to work right away in your home or at your place of business without worrying about software licensing, per-seat workstation or client licenses, software auditing, royalty payments, or any other type of payments to third parties. However, be aware that although much of the software included with Ubuntu is licensed under the GPL, some packages on this book’s disc are licensed under other terms. There is a variety of related software licenses, and many software packages fall under a broad definition known as open source. Some of these include the Artistic License, the BSD License, the Mozilla Public License, and the Q Public License.

For additional information about the various GNU software licenses, browse to www.gnu.org/. For a definition of open-source and licensing guidelines, along with links to the terms of nearly three dozen open-source licenses, browse to www.opensource.org/.

**Who This Book Is For**

This book is for anyone who wants to go beyond basic beginner uses for Ubuntu. Although the contents are aimed at intermediate to advanced users, new users who pay attention will benefit from the advice, tips, tricks, traps, and techniques presented in each chapter. Pointers to more detailed or related information are also provided at the end of each chapter.

If you are new to Linux, you might need to learn some new computer skills, such as how to research your computer’s hardware, how to partition a hard drive, and (occasionally) how to use a command line. This book helps you learn these skills and shows you how to learn more about your computer, Linux, and the software included with Ubuntu. Most important, it will help you overcome your fear of the system by learning more about what it is and how it works.
What This Book Contains

Ubuntu Unleashed is organized into seven parts, covering installation and configuration, Ubuntu on the desktop, system administration, programming and housekeeping, and a reference section. A disc containing the entire distribution is included so that you have everything you need to get started. This book starts by covering the initial and essential tasks required to get Ubuntu installed and running on a target system.

If you are new to Ubuntu, read the chapters in Part I, “Installation and Configuration” first. You will learn the following:

- Detailed steps that walk you through installation
- How to configure Ubuntu to suit your tastes
- Foundational knowledge that enables you to understand Ubuntu

Part II, “Desktop Ubuntu,” is aimed at users who want to use Ubuntu on desktop systems. You will learn the following:

- How to access the Internet in traditional and unique ways
- The productivity applications that are included and some others that are available
- How to enjoy multimedia in Ubuntu
- Other options for desktop software
- An introduction to games in Ubuntu

Part III, “System Administration,” covers

- Managing users and groups
- Automating tasks and using shell scripts
- Monitoring system resources and availability
- Backup strategies and software
- Networking
- Remote access

Part IV, “Ubuntu as a Server” gives you the information you need to start building your own file, web, and other servers for use in your home or office.

- File and print servers
- Web servers
- Using FTP for serving files across the Internet and local networks
- Building and deploying email servers
Conventions Used in This Book

A lot of documentation is included with every Linux distribution, and Ubuntu is certainly no exception. It is impossible to cover every option of every command included in the distribution and, going with our intent to help you become fluent, we focus on teaching you how to find information you need while giving a quality overview worthy of the intermediate or advanced user. However, this book offers numerous tables of various options, commands, and keystrokes to help condense, organize, and present information about a variety of subjects.

This edition is also packed full of screenshots to illustrate Ubuntu-specific graphical utilities—especially those related to system administration or the configuration and administration of various system and network services.
To help you better understand code listing examples and sample command lines, several formatting techniques are used to show input and ownership. For example, if the command or code listing example shows typed input, the input is formatted in boldface, as follows:

```
$ ls
```

If typed input is required, as in response to a prompt, the sample typed input also is in boldface, like so:

```
Delete files? [Y/n] y
```

All statements, variables, and text that should appear on your display use the same boldface formatting. In addition, command lines that require root or super-user access are prefaced with the `sudo` command, as follows:

```
$ sudo printtool &
```

Command-line examples that any user can run are prefaced with a dollar sign ($), like so:

```
$ ls
```

The following elements provide you with useful tidbits of information that relate to the discussion of the text:

---

**NOTE**

A note provides additional information you might find useful as you are working. Notes augment a discussion with ancillary details or point you to an article, a whitepaper, or another online reference for more information about a specific topic.

---

**TIP**

A tip contains a special insight or a timesaving technique, as well as information about items of particular interest to you that you might not find elsewhere.

---

**CAUTION**

A caution warns you about pitfalls or problems before you run a command, edit a configuration file, or choose a setting when administering your system.
SIDEBARS CAN BE GOLDMINES

Just because it is in a sidebar does not mean that you will not find something new here. Be sure to watch for these elements that bring in outside content that is an aside to the discussion in the text. You will read about other technologies, Linux-based hardware, and special procedures to make your system more robust and efficient.

Other formatting techniques include the use of italics for placeholders in computer command syntax. Computer terms or concepts are also italicized upon first introduction in text.

Finally, you should know that all text, sample code, and screenshots in Ubuntu Unleashed were developed using Ubuntu and open-source tools.

Read on to start learning about and using the latest version of Ubuntu. Experienced users will want to consider the new information in this edition when planning or considering upgrades. There are many Linux distributions from different vendors, but many derive from, or closely mimic, the Debian distribution.

CHAPTER 1
Installing Ubuntu

Not that long ago, the mere mention of installing Linux struck fear into the hearts of mortal men. Thanks to a campaign of fear, uncertainty, and doubt (commonly referred to as FUD), Linux garnered a reputation as something of an elitist operating system that could be installed, configured, and used only by extreme computer geeks and professionals. Nowadays, it is a different story entirely, and Ubuntu is one of the easiest distros to install. In this chapter, we cover how to get started with the install disc, including booting into Ubuntu Live CD to test your system. Then we cover the actual installation of Ubuntu, looking at the various options available. The whole process is pain free with Ubuntu, as you are about to learn.

Before You Begin the Installation

Installing a new operating system is a major event, and you should make sure that you have properly thought through what is going to take place. The first thing to consider is how the hardware will be affected by the software that you propose to install. Although Ubuntu will run well on a wide variety of hardware, it is worth while checking your hardware components because there may be a banana skin waiting for you to slip on. This section provides some areas for you to investigate and think about, and may even save you hours of frustration when something goes wrong. Problems are becoming less frequent, but they still crop up occasionally.

You start by researching and documenting your hardware. This information will prove helpful later on during the installation.
Reseaching Your Hardware Specifications

At the absolute minimum, you should know the basics of your system, such as how much RAM you have installed and what type of mouse, keyboard, and monitor you have. Knowing the storage capacity and type of hard drive you have is important because it will help you plan how you will divide it up for Ubuntu and troubleshoot if problems occur. A small detail, such as whether your mouse uses the USB or PS/2 interface, will ensure proper pointer configuration—something that should happen without any problem, but you will be glad you knew in case something does go wrong! The more information you have, the better prepared you will be for any problems.

You can make an inventory or at least a quick list of some basic features of your system. Again, the items you most want to know include the amount of installed memory, the size of your hard drive, the type of mouse, the capabilities of the display monitor (such as maximum resolution), and the number of installed network interfaces (if any).

Installation Options

Ubuntu is made available in three main forms: the Desktop CD, the Server install CD, and the Alternate install CD (we are not including derivative distributions like Kubuntu or Ubuntu Netbook edition in this list). For most people, the Desktop CD will be what you want; the alternate is mainly used for upgrading existing Ubuntu users to the latest version, as well as allowing installation on either low-powered systems or in places where fine-tuned, custom requirements exist. The Server install CD can get a LAMP server up and running in about 20 minutes (Linux, Apache, MySQL, and PHP), but as you will learn in this book, all these components are available to the Ubuntu default distribution.

Planning Partition Strategies

Partitioning is a topic that can make novice Linux users nervous. Coming from a Microsoft world, where you might be used to having just one hard drive, it can seem a bit strange to use an operating system that makes partitioning a hard drive possible or even preferable and common.

Depending on your needs, you can opt to have a single large partition to contain everything, or you may prefer to segment your installation across several partitions to match your individual needs.

If you are installing Ubuntu in a corporate or business environment, the needs of the business should be a primary concern. Be careful to ensure that you build in an adequate upgrade path that allows you to extend the life of the system and add any additional storage or memory.

Knowing how software is placed on your hard drive for Linux involves knowing how Ubuntu organizes its file system. This knowledge will help you make the most out of hard drive space. In some instances, such as when you’re planning to have user directories mounted via NFS or other means, this information can help head off data loss, increase security, and accommodate future needs. Create a great system, and you’ll be the hero of
information services. The Linux file system is covered along with commands to manipulate files and directories in Chapter 4, “Command Line Quickstart.”

To plan the best partitioning scheme, research and know the answers to these questions:

- How much disk space does your system require?
- Do you expect your disk space needs to grow significantly in the future?
- Will the system boot only Ubuntu, or do you need a dual-boot system?
- How much data will require backup, and what backup system will work best? (See Chapter 13, “Backing Up” for more information on backing up your system.)

**DVD INSTALLATION JUMP START**

To install Ubuntu Desktop from the disc included with this book, you must have at least a 1GHz Pentium 4 CPU, 5GB of hard drive space, and 512MB RAM. A monitor with a display resolution of 1024 x 768 is strongly recommended.

**The Boot Loader**

During installation, Ubuntu automatically installs GRUB2 (Grand Unified Boot Loader) to the Master Boot Record (MBR) of your hard drive. Handily enough, it also detects any other operating systems, such as Windows, and adds entries in GRUB2 as appropriate. If you have a specific requirement not to install GRUB2 to the MBR, you need to install using the Alternate disc, which will allow you to specify the install location for GRUB2.

**Installing from CD or DVD**

The BIOS of most PCs support booting directly from a CD or DVD drive and enable you to set a specific order of devices (such as floppy, hard drive, CD-ROM, or USB) to search for bootable software. Turn on your PC and set its BIOS if required (usually accessed by pressing a Function or the Del key after powering on); then insert your Ubuntu install media and boot to install Ubuntu.

**Step-by-Step Installation**

This section provides a basic step-by-step installation of Ubuntu from the install disc. The install process itself is fairly straightforward, and you should not encounter any real problems.

It is useful to have your computer ready to connect to the Internet so that you can download updates as soon as you have finished the installation. Although it’s typically recommended to not have your computer connected up, Ubuntu’s unique security configuration means that it effectively blocks all incoming network ports, so it is fairly secure until you start opening these ports.
Installing

To get started, insert the DVD into your drive and reboot your computer. The initial screen offers a variety of languages for you to use during installation (see Figure 1.1) and two options. Try Ubuntu boots and runs Ubuntu from the CD without making any changes to your system so that when you remove the CD and reboot, everything will be as it was before. Install Ubuntu will install Ubuntu alongside or instead of your current operating system. Select Install Ubuntu to begin.

FIGURE 1.1 Choose a language for the installation in this opening screen.

Figure 1.2 shows the Preparing to Install Ubuntu screen. If you select the two check boxes at the bottom, Ubuntu downloads extra software, such as multimedia codecs and any software updates that have been released since the disk was created, and includes them in the installation. Doing so is recommended.

If other operating systems are found on your system, you will be given the option to install Ubuntu alongside them or to erase them and use the whole disk for Ubuntu.

Next, you have the option to either erase and use the entire hard disk for your installation (recommended for people who are new to Linux and are nervous about partitioning a hard drive) or specifying partitions manually, which is not as difficult as it sounds, as shown in Figure 1.3.

Because this is a book for people who want a deeper understanding of their system, we recommend a simple partitioning scheme here and give some reasons for our choices.
FIGURE 1.2 Before proceeding, double-check that your system meets the requirements shown.

FIGURE 1.3 What do you want to do with your hard drive?

Your needs may vary, so we give some principles to consider so that you may adjust our recommendations to your situation.

Most users will benefit from three simple partitions, shown in Figure 1.4. Here we have a swap partition, a root partition (denoted by /), and a home partition where data for each
user on the system will be stored. The swap partition was previously used for those times when there was not enough memory for running processes, so the Linux kernel could move stored information from RAM to the hard drive and use that swap space as extra RAM. This is slow, but there are times when it is quite useful. These days, desktop systems come with more memory, and the swap space is used mainly for storing information during suspend and hibernate, which can be used instead of turning your computer off. Having /home on a separate partition is a good idea because it enables you to install a different Linux distribution or a different release of Ubuntu on your / partition while retaining your user data.

![Allocate drive space](image)

**FIGURE 1.4** A simple, but useful partitioning scheme.

**NOTE**

Suspend saves your current system state to RAM and then turns off power to most of the system, but maintains just enough power use to keep that state saved in RAM. When you restart your system, it comes back quickly and to the same state it was in. Hibernate saves your current system state to the hard disk. These days, it is just as fast to boot from scratch as it is to hibernate and restore, so there isn’t much point in using it.

We recommend a / partition of at least 3GB, a swap partition that is about 1.5 to 2 times the size of your installed RAM, and then using the rest of the disk for /home. More complex systems, such as servers, may find more complex partitioning schemes useful, especially when multiple hard drives are available. Read Chapter 4 for a quick discussion.
of the parts of the Linux file system to get an idea of parts of the file system that could benefit from residing on their own (or even multiple!) partitions or disks.

After you have made your partitioning selections, installation continues by asking about your current location; it helps you select the most appropriate keyboard layout for your system based on that location and the most common language used there, and asks you to enter your name, a username that you will use to login to the system, and a password. You can even choose to encrypt your /home folder during the process.

**CAUTION**

When you set your password, be sure to remember what you entered! If you forget it, you will not be able to do much with your new system because you will not be able to log on to it.

When setting a password, make sure that it has a mixture of letters and numbers to make it more secure. For instance, a good example of a password is T1a5c0p. Although this may seem like garbage at first glance, the easy way to remember it is by remembering the phrase This Is A Good Choice Of Password, shortened to Tiagcop, and finally substituting some of the letters with similar-looking numbers. Experiment with some phrases to see what you can come up with.

While you are doing this, the Ubuntu install has already begun to copy files to your hard drive. This makes the process even faster than it used to be. Now that all necessary information has been input, you will be shown a series of information screens while the installation is completed. These are filled with interesting content about Ubuntu and are worth reading while you wait.

When the process is complete, you will be prompted to restart the computer. Do so, and remove the install media when it is ejected. Then log in when the reboot is complete. That’s it!

In previous editions of this book, this chapter was longer and described a process that was sometimes confusing and fraught with peril. The Ubuntu developers deserve high praise for making this so incredibly easy and fast. The Linux kernel supports more hardware than ever, and the Ubuntu kernel gurus (who make the decisions about what hardware modules to enable, among other things) do a great job so that most hardware works out of the box.

If you do run into trouble, go to ubuntuforums.org as a great first resource, give a list of your hardware (you did make that list we suggested, right?) and any error messages you have received, and you should either find someone who can help you or get some direction to another source of assistance.

**First Update**

It used to be that the first thing that you needed to do with your new system was update it to the latest package versions. You do this mainly to ensure that you have the latest security updates available. Remember that first installation step where we recommended...
checking the box to have software updates downloaded during the installation process? That means these updates were acquired during the installation and that your system should be up-to-the-minute current.

If you want to double-check that you have all the current versions of software and security updates installed, see Chapter 32, “Managing Software,” for assistance.

**Wubi—The Easy Installer for Windows**

Also included on the Ubuntu CD is Wubi, which allows you to install an Ubuntu system within Windows. In effect, Wubi creates a large file to hold all the Ubuntu information and provides a way, using the Windows bootloader, to boot into Ubuntu without having to do any partitioning at all. What’s more, it’s almost as fast as the real thing and much faster than a Live CD. To get started with Wubi, you need to insert the Ubuntu disc into your CD drive while Windows is booted. You’ll see a screen similar to Figure 1.5.

![Figure 1.5 The auto-start menu gives you a gateway to Ubuntu. Click Install inside Windows to start the Wubi installation.](image-url)

Click the option to Install inside Windows to be taken to the next screen; there you can choose some basic configuration options using the drop-down menus, as shown in Figure 1.6.

Wubi creates an image file on your hard drive and modifies the Windows bootloader to allow you to boot into Ubuntu or Windows. Don’t worry, though; your hard disk hasn’t actually been modified, but a rather large file has been created to hold Ubuntu. When you restart your system you’ll see the Ubuntu option, so press the down-arrow key and press Enter to begin booting into your new Ubuntu system.

The first time you start up a Wubi Ubuntu installation, it does some post-installation configuration before loading the GNOME desktop. You now have a fully functional Ubuntu system.
If you decide that you want to do a proper installation, you’ll need to remove Ubuntu and Wubi. Fortunately, as part of the Wubi installation, an entry is added to the Add/Remove Programs tool in Windows allowing you to quickly and easily remove Wubi and the associated Ubuntu installation. Just remember to back up any files that you want to keep!

**Shutting Down**

At some point, you are going to want to shut down your computer. As with most things in Linux, there are different ways to do it. You can use the power icon located in the upper-right corner of your screen and its drop-down menu, as in Figure 1.7. From there you can also choose to hibernate (saves a copy of the running state to disk and shuts down) or suspend (saves the current running state to memory).

![FIGURE 1.6 You can select some configuration options before you start the installation.](image1)

If you are working at the command line, you can immediately shut down your system by using the `shutdown` command like this:

```
$ sudo shutdown -h now
```

![FIGURE 1.7 You have several options in the power icon menu.](image2)
You can also use the shutdown command to restart your computer, as follows:

$ sudo shutdown -r now

For new users, installing Ubuntu is the beginning of a new and highly rewarding journey on the path to learning Linux. For Ubuntu system administrators, the task ahead is to fine-tune the installation and to customize the server or user environment.

Reference

- www.ubuntu.com—The place to start when looking for news, information, and documentation about installing, configuring, and using Ubuntu.
- www.ubuntu.com/desktop/get-ubuntu/download—This page has specific information and links for downloading, burning, and installing the current release of the Ubuntu desktop edition. There are comparable links available from the main page for Ubuntu Netbook and Server editions and other projects.
- www.nwc.com/columnists/1101colron.html—How to use Intel’s Pre-execution Environment (PXE) protocol to remote boot workstations.
Now that the primary task of installing Ubuntu has been completed, you can begin to customize your new operating system. By default, Ubuntu presents you with a pretty blank canvas with which to personalize your experience. Some people choose to stick with the default look and feel, whereas others go for a full makeover.

In this chapter, we’ll take a look at getting up and running with Ubuntu, including a quick tour around the desktop. We will also take a look at some of the ways in which you can customize your Ubuntu installation and show you how to do some basic administration tasks. By the end of this chapter, you should feel comfortable enough to move on through the rest of the book.

NOTE

Throughout this chapter, we introduce you to several key applications relevant also to other chapters of this book. We include them here because they are essential to getting your system to work as you intend. You will find it worthwhile to refer back to this chapter as you work your way through the book.

Troubleshooting Post-Installation Configuration Problems

A lot of work has gone into Ubuntu to make it as versatile as possible, but sometimes you may come across a piece of hardware that Ubuntu is not sure about. Knowing what to
do in these situations is important, especially when you are working with Ubuntu for the first time.

Because Ubuntu (and Linux in general) is built on a resilient UNIX foundation, it is much more stable than some operating systems. However, even though things might seem to be working fine, Ubuntu could have a problem that might not affect the appearance of the system. In this section, you learn how to examine some of Ubuntu’s built-in error logs to help you discover or diagnose unseen problems. Ubuntu has a command that responds with detailed messages that are output directly by the operating system: the `dmesg` command. This command is commonly used with the `grep` command to filter output. The `dmesg` command takes its output directly from the `/var/log/messages` file, so you can choose to either run `dmesg` or to read the file directly by typing `less /var/log/messages`. The output is fairly detailed, so be prepared for an initial shock when you see how much information is generated. You might find it easier to generate a file with the `dmesg` output by using the following command:

```
matthew@seymour:~$ dmesg > dmesg.txt
```

This takes the output from the `dmesg` command and stores it in a new text file called `dmesg.txt`. You can then browse it at your leisure using your choice of text editor, such as `vi` or `emacs`. You can even use the `less` command, like so:

```
matthew@seymour:~$ less dmesg.txt
```

The messages are generated by the kernel, by other software run by `/etc/init.d`, and by Ubuntu’s runlevel scripts. You might find what appear to be errors at first glance, but some errors are not really problems (for example, if a piece of hardware is configured but not present on your system).

Thanks to Google, troubleshooting is no longer the slow process it used to be. You can copy and paste error messages into Google’s search bar to bring up a whole selection of results similar to the problem you face. Remember, Google is your friend, especially www.google.com/linux, which provides a specialized search engine for Linux. You can also try http://marc.info, which browses newsgroup and mailing list archives. Either way, you are likely to come across people who have had the same problem as you.

It is important to work on finding and testing only one solution to one problem at a time; otherwise, you may end up getting no work done whatsoever. You should also get into the habit of making backup copies of all files that you modify, just in case you make a bad situation worse. Use the copy command like this:

```
matthew@seymour:~$ cp file file.backup20101010
```

You should not use a .bak extension on your backup file because this could get overwritten by another automatic process and will leave you frustrated when you try to restore the original file. I like to use backupYYYYMMDD, as in the preceding code where I used the release date for Ubuntu 10.10: 2010(year)10(month)10(day).

If something breaks as a result of your changing the original file, you can always copy the original back into place using the command like this:

```
matthew@seymour:~$ cp file.backup20101010 file
```
(Something as simple as this can really save your bacon, especially when you are under pressure because you’ve changed something you shouldn’t have changed on a production system. It is better not to make sweeping changes on a production system!)

**The sudo Command**

You will find as you work through this book that Ubuntu relies on the `sudo` command while working at the command line. This command is used in front of other commands to tell Ubuntu that you want to run the specified command with super-user powers. This sounds really special, and it actually is. When you work using the `sudo` command, you can make wide-ranging changes to your system that impact the way it runs. Be extra careful when running any command prefixed with `sudo`, however; a wrong option or incorrect command can have devastating consequences.

The use of `sudo` is straightforward. All you have to do is enter it like this:

```
matthew@seymour:~$ sudo command commandoptions
```

Just replace the word `command` with the command that you want to run, along with any options. For example, the following command opens your `xorg.conf` file in `vi` and enables you to make any changes as the super-user before being able to save it:

```
matthew@seymour:~$ sudo vi /etc/X11/xorg.conf
```

Whenever you execute a command using `sudo`, you are prompted for your password. This is the same password that you use to log in to Ubuntu, so it is important that you remember it.

Sometimes, however, you may want to work with a classic root prompt instead of having to type `sudo` in front of every command (perhaps if you have to work with lots of commands at the command line that require super-user access, for example). `sudo` enables you to do this by using the `sudo -i` command. Again, you are prompted for your password, which you should enter, after which Ubuntu gives you the standard root prompt, as follows:

```
matthew@seymour:~#
```

From here, you can execute any command without having to keep entering `sudo`.

**Software Update**

This topic is covered in greater detail in Chapter 32, “Managing Software,” but it is worthy of a quick mention now so that from the start you can benefit from any available security and bug fixes. The easiest way to check for updates is Update Manager, which is really a GUI wrapper for the command `apt-get`. Open Update Manager from the menu at System, Administration, Update Manager. When the window opens, click Check and enter your password. Update Manager then checks the Ubuntu software repositories to determine whether any updates are available. When it detects that new versions of installed software...
are available, they will appear in the window. Each one has a check box that you can uncheck if you don’t want to install a particular software update. Then click Install Updates to complete the process (Figure 2.1). Software repositories are discussed later in this chapter.

Another way of updating your system is to use the command line. This is vital on servers that do not have a GUI installed, and it is sometimes quicker than using Update Manager on a desktop computer. I like to use the command line to manage all the computers on my home network because I can use SSH to connect to each from a terminal and perform updates from another room in the house, and anyone using that computer is left undisturbed. You will learn how to connect like this later in the book; I just want to whet your appetite for now.

To use the command line, go to the Applications, Accessories menu and select Terminal. This is the command line (commonly referred to as the terminal) and is one of the most powerful features of Linux. It is covered in more detail in Chapter 4, “Command Line Quickstart,” and Chapter 35, “Command Line Masterclass,” so we won’t delve too deeply here.

You are greeted with a prompt similar to the one here:

```
matthew@seymour:~$
```

A blinking cursor also displays. Ubuntu is awaiting your first command. Here we want to issue the following command:

```
matthew@seymour:~$ sudo apt-get update
```

**FIGURE 2.1** Update Manager showing available software updates.
This command tells the package management utility `apt-get` to check the Ubuntu repositories and look for any updates to your installed software. In a matter of seconds, Ubuntu completes all of this, and your screen should look something like this:

```
matthew@seymour:~$ sudo apt-get update
[sudo] password for matt:
Hit http://security.ubuntu.com maverick-security Release.gpg
Hit http://us.archive.ubuntu.com maverick Release.gpg
Ign http://us.archive.ubuntu.com maverick-updates Release.gpg
Hit http://security.ubuntu.com maverick-security/main Sources
Hit http://us.archive.ubuntu.com maverick Release
Hit http://us.archive.ubuntu.com maverick-updates Release
Hit http://security.ubuntu.com maverick-security/restricted Sources
Hit http://security.ubuntu.com maverick-security/universe Sources
Hit http://security.ubuntu.com maverick-security/multiverse Sources
Hit http://security.ubuntu.com maverick-security/main i386 Packages
Hit http://security.ubuntu.com maverick-security/universe i386 Packages
Hit http://security.ubuntu.com maverick-security/multiverse i386 Packages
```
Upgrade your software by entering:

```
matthew@seymour:~$ apt-get dist-upgrade
```

Because you have already checked for updates, Ubuntu automatically knows to download and install only the packages it needs. The dist-upgrade option works intelligently to ensure that any dependencies that are needed can be satisfied and will be installed, even if major changes are needed. You can also use the option upgrade. Upgrade isn’t as smart as dist-upgrade, but may be a better choice on a production server. Upgrade will not make major changes to software installations, but only those necessary for security and simple package updates. This allows the systems administrator more flexibility to keep up to date with security but keep running setups otherwise unchanged.

### Command Line APT-Get Alternatives

Ubuntu has an alternative to apt-get called aptitude. It works in pretty much the same way as apt-get with the exception that aptitude also includes any recommended packages on top of the requested packages when installing or upgrading. You use aptitude mostly the same as you use apt-get; for instance, you could issue the command aptitude update and it would update the repository information. To upgrade, the options are aptitude safe-upgrade and aptitude full-upgrade. You can also issue the command aptitude without any options, which brings up a text-based package manager that you can use to select packages.

---

**Configuring Software Repositories**

Ubuntu uses software repositories to get information about available software that can be installed on your system. Ubuntu is based on a much older Linux distribution called Debian. Debian has access to tens of thousands of different packages, which means that...
Ubuntu has access to these packages, too. The Debian packages are made available in Ubuntu’s Universe repository. A set of volunteers called Masters of the Universe (MOTUs) are well trained and follow strict guidelines to package software and make even more packages available to Ubuntu users in Universe. The Universe repository is filled with optional and often useful or fun software and is enabled by default, along with other official repositories containing software necessary for Ubuntu to be installed and run in all its various official forms, security updates, and software updates.

You can adjust which repositories are enabled using the Software Sources GUI tool, available in Update Manager by clicking Settings. On the first tab (Ubuntu Software), you have five options to choose from. The default settings are shown in Figure 2.2. It is entirely up to you which options you check, but make sure that as a minimum the first check box is checked to allow you access to Canonical-supported Open Source software, which includes all the packages necessary for a basic Ubuntu installation and a few more that are commonly used. The more boxes you check, the wider your selection of software. It's also a good idea to make sure that the Proprietary Drivers for Devices box is checked in order to benefit from drivers that could enhance your system's performance.

![Software Sources](image)

**FIGURE 2.2** You can find or add other options under the Updates and Other Software tabs.

**OPEN SOURCE VERSUS PROPRIETARY**

You may hear some arguments about using proprietary drivers or other software in Ubuntu. Some people feel that it goes against what Open Source stands for because the program code that is used for the drivers or software cannot be viewed and modified by the wider community but only by the original developers or company that owns it. There is also a strong argument that says users should have to undergo the least amount of work for a fully functional system.
Ubuntu takes a middle-of-the-road stance on this and leaves it up to the user to decide. Open source software is installed by default, but options are given to allow proprietary software to be installed easily.

After you are happy with your selections, switch to the Updates tab to configure Ubuntu’s behavior when updates are available (see Figure 2.3). By default, both the important security updates and recommended updates are checked to ensure that you have the latest bug fixes and patches. You can also choose to receive proposed updates and backports (software that is released for a newer version of Ubuntu but re-programmed to be compatible with the current release), but we’d recommend this only if you are happy to carry out testing for the community, because any updated software from these repositories can have an adverse effect on your system.

![Software Sources](image)

**FIGURE 2.3** Configure which updates you want, and you want them to be handled in the Updates tab of Software Sources.

Ubuntu also allows you to configure how often it checks for updates, as well as how they are installed. By default, Ubuntu checks daily for updates and, if any are available, will notify you. However, you can change the frequency and the actions Ubuntu carries out when it finds available updates. We recommend keeping the notification-only option because this allows you to see what updates are available prior to them being installed. If you want to save time, choose Download All Updates in the Background to configure Ubuntu to silently download the updates before giving you the option to install them.
CAUTION

We don’t recommend selecting the option that automatically installs security updates. It’s important that you have the option of choosing to install updates, because there is always the chance that an update may cause problems. The last thing you want is for your system to suddenly stop working because an update was installed that has broken something without your knowledge.

Part of the magic of Ubuntu is the ease in which you can upgrade from major version to major version, such as moving from 10.04 to 10.10. Some Ubuntu releases are called LTS, for Long Term Support, and are intended for those who do not want to upgrade their operating system as often. It is possible to do this. By ensuring that the release upgrade option is set to Long Term Supported releases only, you’ll be prompted to upgrade your version of Ubuntu only to what will be the next Long Term Supported version, which is scheduled to be 12.04, to be released in April of 2012.

The Other Software tab lets you add other repositories. It comes by default with everything you need to connect to and use Canonical’s partner repository, with non-free (usually in the licensing sense, but occasionally for payment) software from companies that have an agreement with Canonical to make it easily available to interested users. This repository is disabled by default and you must enable it by checking a box next to its entry in the Other Software tab if you want to use it.

Installing Graphics Drivers

Ubuntu is extremely good at detecting and configuring graphics cards. You can check whether you have a video card or some other piece of hardware that could benefit from using a proprietary driver with the Additional Drivers Manager. When you open it, it scans your system, and then you can choose to enable or disable any proprietary drivers found, depending on your personal preference. (See the “Open-Source Versus Proprietary” note earlier in this chapter.)

You can find the Additional Drivers Manager under the System, Administration menu, which is shown in Figure 2.4.

If you elect to use a listed proprietary driver, Ubuntu will first confirm that you are happy to proceed and then automatically download and install the driver. This may require you to log out and back in again for the driver to take effect.

For the most part, Ubuntu will detect and configure the majority of graphics cards from the start, and even if it has problems, it will attempt to give you a display of some sort. This feature is known as BulletProof X, and it allows you access to tools that may help you fix your problem by trying different combinations of graphics cards and monitors.
Changing Ubuntu’s Look and Feel

GNOME, the default window manager for Ubuntu, has a number of options to change how it looks and feels. The default theme is Human; this takes a blend of the GNOME Clearlooks theme, mixes it with icons from the Tango Project, and adds a little spice direct from Ubuntu. However, it is not to everyone’s taste, so in this section we look at changing the visual style of Ubuntu.

Changing the Desktop Background

Perhaps the easiest and most dramatic change you can make is to change the default desktop background. It is as simple as right-clicking on the desktop and selecting the option to Change Desktop Background to see the dialog box shown in Figure 2.5. Ubuntu comes with a small selection of wallpaper to start with, but you can add others. One favorite source is http://art.gnome.org/backgrounds/, where you can find a great selection of desktop wallpaper and which is linked from Get More Backgrounds Online.

As you click a wallpaper, Ubuntu automatically applies it so that you can quickly see whether you like it. When you are happy with your selection, keep the dialog box open so we can change other aspects of the desktop.
Changing Colors

Next up are the colors that Ubuntu defaults to. When Ubuntu was originally launched in October 2004, it came with a predominantly brown theme, which over time turned to caramel color, and later to orange. Ubuntu 10.04 introduced a new color scheme using aubergine (purple) and orange and a new overall theme. The theme may be changed as well as the colors it uses. Select System, Preferences, Appearance from the menu. Or if you’ve kept the dialog box open from the previous section, click the Theme tab. You will see a list of predefined themes that you can choose from (see Figure 2.6).

Alternatively, you can click the Customize button to mix up your own look and feel, as shown in Figure 2.7. You can choose to change the window decorations (title bar, minimize, maximize buttons, and so on), the general color scheme, and the icon theme. As you select an option, Ubuntu automatically applies it to the desktop so you can get an idea of how it will look. When you’re happy with your selections, click Close to return to the main Theme dialog box and move on to the next section.
FIGURE 2.6 Either use the default themes or mix and match elements of them to match your specifications.

FIGURE 2.7 Use any number of combinations of icons, colors, and window decorations to give you a truly personalized look and feel.
Modifying System Fonts

GNOME also enables you to change the fonts used throughout Ubuntu. If you have difficulty reading one font, just exchange it for another.

In the Appearance dialog box you will see a tab called Fonts. Click this tab to see the options available for changing system fonts, which are shown in Figure 2.8. Click each font name to customize the font used for that function.

For instance, you may prefer your Window Title Font to be italicized, so click the font name and select the Italic option. Clicking OK immediately applies the change, again giving you a good idea of whether it works. Sometimes a font can look good within the Font Preferences screen, but when it comes to using it, you wonder why on earth you chose it. Choose your fonts wisely!

Visual Effects

Perhaps the most exciting part of Ubuntu is that it comes by default with some snazzy visual effects to enhance the look and feel of your desktop. Click the Visual Effects tab to see the options available for configuring the level of effects, shown in Figure 2.9. In keeping with Ubuntu’s philosophy of keeping things simple, there are three options to
choose, from which you can elect to turn off all visual effects, use a basic set of effects, or use a lot of visual effects. If you choose this last option you will need to have a relatively fast computer with plenty of memory (at least 1GB) and a decent video card to ensure that the computer doesn’t grind to a halt while rendering effects.

![Appearance Preferences](image)

**FIGURE 2.9** Wow your friends and colleagues by activating visual effects to enhance your user experience. Alternatively, switch them all off if you get a bit overwhelmed by windows flying everywhere!

**Preferred Behaviors**

Ubuntu can detect and adapt to certain events. Sometimes you may want Ubuntu to open one application rather than another, or sometimes to not do anything at all. This is called Ubuntu’s behavior, and you can modify it to work as you want it to. From the System, Preferences menu, select Preferred Applications.

Preferred applications are the applications that Ubuntu calls on when it wants to open an Internet site, an email, or a terminal (see Figure 2.10). Ubuntu makes it easy for you by automatically detecting the available options. Alternatively, if you want to specify your own particular application that may not appear in the list by default, select the Custom
option within the application type and enter the command used to launch the applica-
tion into the field along with any options, arguments, or switches that you want to use.

![Preferred Applications](image.png)

FIGURE 2.10 Setting preferred Internet applications.

**Input Devices**

The primary interface between you and your computer is your keyboard and mouse. Both of these are essential to the correct usage of your computer, so it is important that they are configured correctly. Windows users will be familiar with the basic options, so it could come as somewhat of a shock to learn that you can do a few more nifty things with a keyboard and mouse in Ubuntu.

**Keyboard Shortcuts**

If you have used a computer for more than a few years, you probably use keyboard short-
cuts for popular commands. Ubuntu allows you to set your own keyboard shortcuts for a variety of system commands. The easy-to-use Keyboard Shortcuts option under System, Preferences lists a lot of actions that you can program shortcuts for (see Figure 2.11).

If you have one of those multimedia keyboards with lots of extra keys, this is the place to configure their use. Just click the shortcut next to the action you want to configure and press the key that you want to map to this action. Repeat this until you have exhausted all the combinations that you want to configure. Then click Close to finish.
Make your life easier and your work go more quickly by configuring useful keyboard shortcuts.

**Keyboard Layout**

Getting the layout of your keyboard right can make a huge difference in how you work. When you installed Ubuntu (see Chapter 1), you specified the default keyboard layout to use. However, there may be times when you need to switch layouts, which you can do using the Keyboard option in the System, Preferences menu (see Figure 2.12).

![Keyboard Shortcuts](image1.png)

**FIGURE 2.11** Make your life easier and your work go more quickly by configuring useful keyboard shortcuts.

![Keyboard Preferences](image2.png)

**FIGURE 2.12** Use the Keyboard Layout tool to ensure that you have your keyboard settings configured correctly.
I often use this because I also install support for other languages and occasionally type using those languages. This is also valuable for people who prefer to type using Dvorak or other keyboard layout variations within a language group, such as those who prefer either the U.S. or UK variant of the English keyboard (which have different locations for some of the symbols).

You can also use the Keyboard Layout tool to configure special key behaviors. For instance, some people prefer to swap the Caps Lock and left Ctrl key around. You can set this option and others in the Layouts tab by clicking Options. Experiment with what is available here; you may come up with some customization ideas that are useful to you.

Ubuntu can also configure and enforce typing breaks, all in the name of good health. Simply set the length of working time, the duration of the break, and whether you want to be able to postpone. When this is activated at the end of the first length of working time, Ubuntu locks the computer and will not let you log back in until the break duration has passed. However, if you are in the middle of something important, setting the Postpone option may prove useful.

Mouse

There’s not much to configuring a mouse. Ubuntu does a great job of detecting most mice. The most useful option from System, Preferences, Mouse is the Locate Pointer option, which highlights the mouse pointer when you press the Ctrl key. If you are left-handed, you can also swap the mouse buttons over, but this is a matter of personal preference.

Detecting and Configuring a Printer

Setting up a printer in Linux used to be so difficult that previous editions of this book included an entire chapter filled with command-line magic and scary looking configuration files. This is no longer the case most of the time. Ubuntu includes drivers for many printers, and it is usually easier to install and use a printer in Ubuntu than in other operating systems. This is not an absolute rule, though. Some printer manufacturers will not write and release drivers for Linux and for some printers, no open source driver exists. It is still a very good idea to spend some time on the Internet searching for printers that are well known to work with Linux before buying. One great resource is the Open Printing database from The Linux Foundation at www.openprinting.org/printers.

If you choose wisely, all you need to do is plug your printer into the computer and turn it on. In many cases, Ubuntu will find the printer and add the driver automatically. Within a couple of minutes, you should be able to use it. You can go to System, Administration, Printing to see all installed and configured printers and change their settings. From here you can choose to enable printer sharing on a network, set options for default print quality, print a test page, and more.
Configuring Power Management in Ubuntu

System, Preferences, Power Management gives you control of how Ubuntu will handle power-saving features in specific situations (Figure 2.13). You can have the display dim the backlight to use less power when on battery, put the display to sleep after a certain amount of inactivity, spin down your hard disks (kind of like turning them off, but not completely; this just makes them stop moving until a request is made from them, saving power in the interim) and set your computer to suspend, hibernate, or turn off when the battery reaches a certain level.

Ubuntu provides good support for suspend and hibernate. Suspend means that your computer writes its current state to memory and goes into a low-power mode, whereas Hibernate writes the current state of the system to disk and powers off the computer. Either way, your computer will start much faster the next time you use it.

Setting the Date and Time

Linux provides a system date and time; your computer hardware provides a hardware clock-based time. In many cases, it is possible for the two times to drift apart. Linux system time is based on the number of seconds elapsed since January 1, 1970. Your computer’s hardware time depends on the type of clock chips installed on your PC’s motherboard, and many motherboard chipsets are notoriously subject to drift.

Keeping accurate time is important on a single workstation, but it is critically important in a network environment. Backups, scheduled downtimes, and other networkwide actions need to be accurately coordinated.
The Ubuntu installer sets the date and time during the installation process when it asks for your location. If you move or just want to change the settings, for example, to have your computer automatically synchronize its clock with official time servers on the Internet, you can do so.

Ubuntu provides several date and time utilities you can use at the command line or during a GUI session, including these:

- `time-admin`—Ubuntu’s graphical date, time, and network time configuration tool
- `date`—Used to display, set, or adjust the system date and time from the command line
- `hwclock`—A root command to display, set, adjust, and synchronize hardware and system clocks

**Changing the Time and Date**

Ubuntu’s graphical tool is the simplest way to set your system date and time and the most obvious for a desktop user. The client is found in System, Administration, Time & Date.

To make any changes to this tool, you need to unlock it by clicking the Unlock button. Only a user who has administrator privileges may use this tool, and you will need to enter your password to authenticate. After you’ve done this, you are able to change any of the options.

Manually set the date and time in the GUI (Figure 2.14), or have your computer obtain updated date and time information via the Internet by changing the Configuration setting and selecting Keep Synchronized with Internet Servers. To do this, you need to have `ntpd` time daemon support installed. If it is not present, Ubuntu asks whether you want to retrieve it, and then installs it so that you can proceed. After it has been installed, you will be able to select specific Internet time servers to synchronize with (Figure 2.15). You should choose servers close to your location.

![Figure 2.14](image-url) You can manually set your system date and time.
FIGURE 2.15 Select specific Internet time servers close to your location.

Using the `date` Command

Use the `date` command to display or set your Linux system time. This command requires you to use a specific sequence of numbers to represent the desired date and time. To see your Linux system’s idea of the current date and time, use the `date` command like this:

```
matthew@seymour:~$ date
Sat Sep  4 10:20:51 MST 2010
```

To adjust your system’s time (for example, to September 4, 2010 at 10:33 a.m.), use a command line with the month, day, hour, minute, and year, like so:

```
matthew@seymour:~$ sudo date 090410332010
Sat Sep  4 10:33:00 MST 2010
```

Using the `hwclock` Command

Use the `hwclock` command to display or set your Linux system time, display or set your PC’s hardware clock, or to synchronize the system and hardware times. To see your hardware date and time, use `hwclock` with its `—show` option, like so:

```
matthew@seymour:~$ sudo hwclock —show
Sat 04 Sep 2010 05:25:17 PM MST  -0.806770 seconds
```

Use `hwclock` with its `—set` and `—date` options to manually set the hardware clock, like so:

```
matthew@seymour:~$ sudo hwclock —set —date "09/04/10 10:33:00"
matthew@seymour:~$ hwclock —show
Sat 04 Sep 2010 10:33:09 AM MST  -0.904668 seconds
```
In these examples, the hardware clock has been set using `hwclock`, which is then used again to verify the new hardware date and time. You can also use `hwclock` to set the Linux system date and time using your hardware clock’s values with the Linux system date and time.

For example, to set the system time from your PC’s hardware clock, use the `--hctosys` option, like so:

```bash
matthew@seymour:~$ sudo hwclock --hctosys
```

To set your hardware clock using the system time, use the `--systohc` option, like so:

```bash
matthew@seymour:~$ sudo hwclock --systohc
```

---

**Configuring Wireless Networks**

Wireless networking used to be a bear to configure for Linux, requiring a lot of complicated steps to connect to a wireless network. That has become a much easier task, and Ubuntu includes a great utility called Network Manager that makes connecting to and managing wireless networks extremely easy.

When you log in to Ubuntu, you should see the Network Manager applet appear in the top panel (see Figure 2.16). This is the applet that handles and monitors network connections.

![Network Manager applet](image)

**FIGURE 2.16** The Network Manager notification applet, shown here already connected to a wireless network.

Click the applet icon in the toolbar to connect to a wireless network. If your wireless access point broadcasts its SSID, it should appear in the list under wireless networks (similar to Figure 2.16). Click the desired network, and Network Manager will detect what encryption (if any) is in use and ask you for the passkey. Enter this and Network Manager will start the
wireless connection. The passkey is then stored in the default keyring, a secure area that is unique to your login. From now on, whenever you log in to Ubuntu and are in range of this network, Network Manager will start the connection automatically.

If for some reason your wireless network does not appear (you might have your SSID hidden), you must use the Connect to Other Wireless Network option, in which you will enter the network name, wireless security type, and when needed, the password for the connection.

Network Manager can handle WEP and WPA Personal encryption. You are advised to use WPA encryption because it is the stronger of the two. WEP encryption is easily broken.

Network Manager can also connect to Cisco VPN connections, using the vpnc software. Install this using synaptic and you will be able to specify connection settings as appropriate or if you have access to a predefined configuration (.pcf file), you can import it directly into Network Manager.

Imagine a world of black screens with white text, or for those of you who remember, dark green screens with light green text. That used to be the primary interface for users to access computers. Computing has moved on significantly and has adopted the graphical user interface, or GUI, as standard on most desktop and workstation platforms.

Ubuntu has a beautiful GUI based on a window manager called GNOME (the Gnu Network Object Model Environment). Based on the ethos of simplicity and elegance, GNOME offers a rich and full interface that you can easily use to be productive. The principal design objective is an intuitive system with sane default settings, meaning that it should be easy to pick up and use, and it also has good localization/internationalization support and accessibility.

 GNOME uses the X Window System, the graphical networking interface found on many Linux distributions that provides the foundation for a wide range of graphical tools and window managers. More commonly known as just X, it can also be referred to as X11R7 and X11 (as found on Mac OS X). Coming from the world-renowned Massachusetts Institute of Technology, X has gone through several versions, each of which has extended and enhanced the technology. The open source implementation is managed by the X.Org foundation, whose board includes several key figures from the open source world.

The best way to think about how X works is to see it as a client/server system. The X server provides services to programs that have been developed to make the most of the graphical and networking capabilities that are available under the server and in the supported libraries. X.Org
provides versions for many platforms, including Linux and Mac OS X. Originally implemented as XFree86, X.Org was forked when a row broke out over certain restrictions that were going to be included in the XFree86 license. Taking a snapshot of code that was licensed under the previous version of the license, X.Org drove forward with its own implementation based on the code. Almost in unison, most Linux distributions turned away from XFree86 and switched their development and efforts to X.Org.

A desktop environment for X provides one or more window managers and a suite of clients that conform to a standard graphical interface based on a common set of software libraries. When they are used to develop associated clients, these libraries provide graphical consistency for the client windows, menus, buttons, and other onscreen components, along with some common keyboard controls and client dialogs. In this chapter you will learn how to work with GNOME and learn something about the version of X that is included with Ubuntu. If you want to learn more about some of the other desktop environments that are available to use with Ubuntu, including KDE and Xfce, take a look at Chapter 8, “Other Ubuntu Desktops.”

### The Ubuntu Family

When people talk about Ubuntu, they generally mean the standard distribution, which uses the GNOME window manager. However, a number of derivatives of Ubuntu use other window managers, and they are freely available for you to download and use. For instance, Kubuntu uses the KDE window manager, whereas Xubuntu uses Xfce. Despite their very visual differences, all three rely on the same core system. It is easy for you to add that window manager to your existing system by using one of the *-desktop meta-packages. These packages are designed to install all the base applications that are linked to that version of Ubuntu, so installing the kubuntu-desktop package would automatically install all the software needed for Kubuntu while retaining your existing desktop environment.

### The GNOME Desktop Environment

The GNOME project, which was started in 1997, is the brainchild of programmer whiz Miguel de Icaza. GNOME provides a complete set of software libraries and clients. GNOME depends on a window manager that is GNOME-aware. This means that to provide a graphical desktop with GNOME elements, the window manager must be written to recognize and use GNOME. Some compliant window managers that are GNOME-aware include Compiz (the default GNOME window manager in Ubuntu), Metacity (the fallback if the hardware being used is not powerful enough for Compiz), Enlightenment, Window Maker, and IceWM.

Ubuntu uses GNOME's user-friendly suite of clients to provide a consistent and user-friendly desktop. GNOME clients are found under the /usr/bin directory, and GNOME configuration files are stored under the /etc/gnome and /usr/share/gnome directories, with user settings stored in the home directory under .gnome and .gnome2.

The standard Ubuntu desktop is shown in Figure 3.1.
You can configure your desktop in various ways and by using different menu items under the Preferences menu, which can be found as part of the main Desktop menu. The myriad of configuration options allow you to tailor every aspect of your system’s look and feel, as discussed in Chapter 2, “Post-Installation Configuration.”

**Eye Candy for the Masses**

Recent development work carried out on X has allowed the introduction of a number of hardware-accelerated effects within Ubuntu and its window managers. No longer do you have to drool at your Mac OS X-using colleagues when they work; now Ubuntu has a whole load of “wow” effects designed to add that professional touch to Linux. In fact, you colleagues will probably be drooling over your setup. If your graphics card is powerful enough, the desktop effects will be available out of the box.

Ubuntu uses the Compiz window manager, which to most end users will not appear any different from Metacity, the standard window manager in use by Ubuntu. You should already have the latest graphics card driver for your system installed. To check, see System, Administration, Additional Drivers. Check out Chapter 2 for more information on this tool.

After you have verified you have the best graphic driver installed, look at the menu option under System, Preferences called Appearance (see Figure 3.2). Open it up and select the Visual Effects tab. By default this is set to None, but try setting it to Normal or Extra to see
what happens. After a couple of seconds you may see your window decorations (title bar, minimize and maximize buttons) disappear and then reappear. It may seem that nothing has happened, but grab hold of the window title bar and move it around. If everything has gone according to plan, it should wobble! Click Close to save the settings, and welcome to a world of fancy effects.

![Appearance Preferences](image)

FIGURE 3.2 Use the Visual Effects tool to set the scene for some snazzy 3D effects.

The most obvious effect is that of “wobbly windows,” which provide a fluid effect when you move your windows around the desktop area. Have fun exploring the new options and toys you have available. Try installing simple-ccsm from the Ubuntu repositories and playing with the new menu item at System, Preferences, Simple Compiz Config Settings Manager for more control over the flashy fun.

**Basic X Concepts**

The underlying engine of X11 is the X protocol, which provides a system of managing displays on local and remote desktops. The protocol uses a client/server model that allows an abstraction of the drawing of client windows and other decorations locally and over a network. An X server draws client windows, dialog boxes, and buttons that are specific to the local hardware and in response to client requests. The client, however, does not have to be specific to the local hardware. This means that system administrators can set up a network with a large server and clients and enable users to view and use those clients on workstations with totally different CPUs and graphics displays.

Because X offers users a form of distributed processing, Ubuntu can be used as a very cheap desktop platform for clients that connect to a powerful X server. The more powerful
the X server, the larger the number of X-based clients that can be accommodated. This functionality can breathe new life into older hardware, pushing most of the graphical processing on to the server. A fast network is a must if you intend to run many X clients because X can become bandwidth hungry.

NOTE

A great way to demonstrate the capability of X to handle remote clients is Edubuntu’s use of LTSP, covered in Chapter 23, “Linux Terminal Server Project (LTSP).” It is designed to set up a main server and a set of dumb terminals that display programs that are being run on the server.

X is hugely popular in the UNIX and Linux world for a variety of reasons. That it supports nearly every hardware graphics system is a strong point. This and strong multiplatform programming standards give it a solid foundation of developers committed to X. Another key benefit of X is its networking capability, which plays a central point in administration of many desktops and can also assist in the deployment of a thin-client computing environment. Being able to launch applications on remote desktops and also standardize installations highlight the versatility of this powerful application.

More recent versions of X have also included support for shaped windows (that is, nonrectangular), graphical login managers (also known as display managers), and compressed fonts. Each release of X brings more features designed to enhance the user experience, including being able to customize how X client applications appear, right down to buttons and windows. Most office and home environments run Linux and X on their local machines. The more-enlightened companies and users harness the power of the networking features of X, enabling thin-client environments and allowing the use of customized desktops designed specifically for that company. Having applications launch from a single location makes the lives of system administrators a lot easier because they have to work on only one machine, rather than several.

Using X

X.Org 7.5 is the X server that is used with Ubuntu. The base Xorg distribution consists of many packages (well over 100MB) including the server, support and development libraries, fonts, various clients, and documentation. An additional 1,000 or more X clients, fonts, and documentation are also available in the Ubuntu repositories.

The /usr directory and its subdirectories contain the majority of Xorg’s software. Some important subdirectories are

- /usr/bin—This is the location of the X server and various X clients. (Note that not all X clients require active X sessions.)

- /usr/include—This is the path to the files necessary for developing X clients and graphics such as icons.
The main components required for an active local X session are installed on your system if you choose to use a graphical desktop. These components are the X server, miscellaneous fonts, a *terminal client* (that is, a program that provides access to a shell prompt), and a client known as a *window manager*. Window managers administer onscreen displays, including overlapping and tiling windows, command buttons, title bars, and other onscreen decorations and features.

**Elements of the `xorg.conf` File**

Traditionally, the most important file for Xorg has been the `xorg.conf` configuration file. This file contained configuration information that was vital for X to function correctly and was usually created during the installation of Ubuntu.

**BULLET PROOF X**

Ubuntu now comes with a useful feature called Bullet Proof X. In short, it is designed to work no matter what may happen, so in the event of some cataclysmic event that destroys your main X system, you will still have some graphical way of getting yourself back into a fully functional X-based system.

Modern versions of Xorg do not create an `xorg.conf` file by default. Instead, various files ending in `*.conf` reside in the `/usr/share/X11/xorg.conf.d` directory and are automatically loaded by X at boot, prior to reading any `xorg.conf`. These files can each contain one or more sections in the same format used by `xorg.conf`. Users can create the file and continue making custom configurations in `/etc/xorg.conf` as has been traditionally done, but the file is not created by default. What is included in the previously mentioned individual files should not be changed, but you may override those settings by creating your own `xorg.conf` file.

**NOTE**

We will refer to using an `xorg.conf` file from here on, but keep the preceding information in mind to prevent confusion.
Let’s take a look at the potential contents of xorg.conf so that you can get an idea of what X is looking for. The components, or sections, of the xorg.conf file specify the X session or server layout, along with pathnames for files that are used by the server, any options relating directly to the server, any optional support modules needed, information relating to the mouse and keyboard attached to the system, the graphics card installed, the monitor in use, and the resolution and color depth that Ubuntu uses. These are the essential components:

- **ServerLayout**—Defines the display, defines one or more screen layouts, and names input devices.
- **Files**—Defines the location of colors, fonts, or port number of the font server.
- **Module**—Tells the X server what graphics display support code modules to load.
- **InputDevice**—Defines the input devices, such as the keyboard and mouse; multiple devices can be used.
- **Monitor**—Defines the capabilities of any attached display; multiple monitors can be used.
- **Device**—Defines one or more graphics cards and specifies what optional features (if any) to enable or disable.
- **Screen**—Defines one or more resolutions, color depths, perhaps a default color depth, and other settings.

The following sections provide short descriptions of these elements; the xorg.conf man page contains full documentation of all the options and other keywords you can use to customize your desktop settings.

**The ServerLayout Section**

As noted previously, the ServerLayout section of the xorg.conf file defines the display and screen layouts, and it names the input devices. A typical ServerLayout section from an automatically configured xorg.conf file might look like this:

```
Section "ServerLayout"
  Identifier     "single head configuration"
  Screen 0 "Screen0" 0 0
  InputDevice    "Mouse0" "CorePointer"
  InputDevice    "Keyboard0" "CoreKeyboard"
  InputDevice    "DevInputMice" "AlwaysCore"
EndSection
```

In this example, a single display is used (the numbers designate the position of a screen), and two default input devices, Mouse0 and Keyboard0, are used for the session.
The Files Section
The Files section of the xorg.conf file might look like this:

```
Section "Files"
   RgbPath    "/usr/lib/X11/rgb"
    FontPath  "unix:/7100"
EndSection
```

This section lists available session colors (by name, in the text file rgb.txt) and the port number to the X font server. The font server, xfs, is started at boot and does not require an active X session. If a font server is not used, the FontPath entry could instead list each font directory under the /usr/lib/X11/fonts directory, as in this example:

```
FontPath "/usr/lib/X11/fonts/100dpi"
FontPath "/usr/lib/X11/fonts/misc"
FontPath "/usr/lib/X11/fonts/75dpi"
FontPath "/usr/lib/X11/fonts/type1"
FontPath "/usr/lib/X11/fonts/Speedo"
...
```

These directories contain the default compressed fonts that are available for use during the X session. The font server is configured by using the file named config under the /etc/X11/fs directory. This file contains a listing, or catalog, of fonts for use by the font server. By adding an alternate-server entry in this file and restarting the font server, you can specify remote font servers for use during X sessions. This can help centralize font support and reduce local storage requirements (even though only 25MB is required for the almost 5,000 fonts installed with Ubuntu and X).

The Module Section
The Module section of the xorg.conf file specifies loadable modules or drivers to load for the X session. This section might look like this:

```
Section "Module"
    Load  "dbe"
    Load  "extmod"
    Load  "fbdevhw"
    Load "glx"
    Load "record"
    Load "freetype"
    Load "type1"
    Load "dri"
EndSection
```

These modules can range from special video card support to font rasterizers. The modules are located in subdirectories under the /usr/lib/modules directory.
The InputDevice Section
The InputDevice section configures a specific device, such as a keyboard or mouse, as in this example:

```
Section "InputDevice"
  Identifier  "Keyboard0"
  Driver      "kbd"
  Option      "XkbModel"      "pc105"
  Option      "XkbLayout"     "us"
EndSection
```

```
Section "InputDevice"
  Identifier  "Mouse0"
  Driver      "mouse"
  Option      "Protocol" "IMPS/2"
  Option      "Device" "/dev/input/mice"
  Option      "ZAxisMapping" "4 5"
  Option      "Emulate3Buttons" "yes"
EndSection
```

You can configure multiple devices, and multiple InputDevice sections might exist. The preceding example specifies a basic keyboard and a two-button PS/2 mouse (actually, a Dell touchpad pointer). An InputDevice section that specifies use of a USB device could be used at the same time (to enable mousing with PS/2 and USB pointers) and might look like this:

```
Section "InputDevice"
  Identifier  "Mouse0"
  Driver      "mouse"
  Option      "Device" "/dev/input/mice"
  Option      "Protocol" "IMPS/2"
  Option      "Emulate3Buttons" "off"
  Option      "ZAxisMapping" "4 5"
EndSection
```

The Monitor Section
The Monitor section configures the designated display device as declared in the ServerLayout section, as shown in this example:

```
Section "Monitor"
  Identifier   "Monitor0"
  VendorName   "Monitor Vendor"
  ModelName    "Monitor Model"
  DisplaySize  300     220
```
Note that the X server automatically determines the best video timings according to the horizontal and vertical sync and refresh values in this section. If required, old-style mode-line entries (used by distributions and servers prior to XFree86 4.0) might still be used. If the monitor is automatically detected when you configure X (see the “Configuring X” section, later in this chapter), its definition and capabilities are inserted in your xorg.conf file from the MonitorsDB database. This database contains more than 600 monitors and is located in the /usr/share/hwdata directory.

**The Device Section**

The Device section provides details about the video graphics chipset used by the computer, as in this example:

```
Section "Device"
  Identifier      "Intel Corporation Mobile 945GM/GMS,943/940GML Express Integrated Graphics Controller"
  Driver          "intel"
  BusID           "PCI:0:2:0"
EndSection
```

This example identifies an installed video card as using an integrated Intel 945 graphics chipset. The Driver entry tells the Xorg server to load the intel kernel module. Different chipsets have different options. For example, here’s the entry for a NeoMagic video chipset:

```
Section "Device"
  Identifier   "NeoMagic (laptop/notebook)"
  Driver       "neomagic"
  VendorName   "NeoMagic (laptop/notebook)"
  BoardName    "NeoMagic (laptop/notebook)"
  Option     "externDisp"
  Option     "internDisp"
EndSection
```

In this example, the Device section specifies the driver for the graphics card (neomagic_drv.o) and enables two chipset options (externDisp and internDisp) to allow display on the laptop’s LCD screen and an attached monitor.

The Xorg server supports hundreds of different video chipsets. If you configure X11 but subsequently change the installed video card, you need to edit the existing Device section or generate a new xorg.conf file, using one of the X configuration tools discussed in this chapter, to reflect the new card’s capabilities. You can find details about options for some chipsets in a companion man page. You should look at these sources for hints about optimizations and troubleshooting.
The Screen Section

The Screen section ties together the information from the previous sections (using the Screen0, Device, and Monitor Identifier entries). It can also specify one or more color depths and resolutions for the session. Here’s an example:

```
Section "Screen"
    Identifier "Screen0"
    Device     "Videocard0"
    Monitor    "Monitor0"
    DefaultDepth 24
    SubSection "Display"
        Viewport 0 0
        Depth 16
        Modes "1024x768" "800x600" "640x480"
    EndSubSection
EndSection
```

In this example, a color depth of thousands of colors and a resolution of 1024x768 is the default, with optional resolutions of 800x600 and 64x480. Multiple Display subsection entries with different color depths and resolutions (with settings such as Depth 24 for millions of colors) can be used if supported by the graphics card and monitor combination. You can also use a DefaultDepth entry (which is 24, or thousands of colors, in the example), along with a specific color depth to standardize display depths in installations.

You can also specify a desktop resolution larger than that supported by the hardware in your monitor or notebook display. This setting is known as a virtual resolution in the Display subsection. This allows, for example, an 800 X 600 display to pan (that is, slide around inside) a virtual window of 1024 X 768.

NOTE

If your monitor and graphics card support multiple resolutions and the settings are properly configured, you can use the key combination of Ctrl+Alt+Keypad+ or Ctrl+Alt+Keypad- to change resolutions on-the-fly during your X session.

Configuring X

Ubuntu usually does a good job of detecting your graphics card and monitor, although sometimes problems can arise if the PC’s video card is not recognized. If your display is not configured correctly, Ubuntu provides some tools to help you make changes to the way your display is set up.

You can use the gnome-display-properties client to configure your displays. Start in the menu at System, Preference, Monitors. You will see a window similar to Figure 3.3, but with information for your specific hardware.
The Monitor Preferences window shows the current selected screen, along with details of the model, resolutions available, the refresh rate, and orientation. In the event that you are using two screens (dual- or multi-head displays, or when a projector is attached) you have the ability to select whether it is the primary or secondary screen, and the physical location of it. Click Detect Monitors if a second monitor does not appear or if you have just plugged in a projector. Select Same Image in all monitors if you want to mirror your display. Click Apply when you are satisfied with your settings.

Starting X

You can start X sessions in a variety of ways. The Ubuntu installer sets up the system to have Linux boot directly to an X session using a display manager called GDM, for GNOME Display Manager. This is an X client that provides a graphical login. After you log in, you use a local session (running on your computer) or, if the system is configured to do so, an X session running on a remote computer on the network.

Logging in via a display manager requires you to enter a username and password. You can also start X sessions from the command line. The following sections describe these two methods.

NOTE

If you have used the Server install, your system will boot to a text login—see Chapter 4, “Command Line Quickstart,” for more details on what to do here.

Using a Display Manager

An X display manager presents a graphical login that requires a username and password to be entered before access is granted to the X desktop. It also allows you to choose a different desktop for your X session. Whether an X display manager is presented after you boot
Linux is controlled by a runlevel—a system state entry in `/etc/event.d/`. The following runlevels as handled by Ubuntu are as follows:

- 0 - halt (Do NOT set initdefault to this.)
- 1 - Multiuser text mode
- 2 - X – graphical multiuser mode
- 6 - reboot (Do NOT set initdefault to this.)

You may see mention of Runlevels 3 through 5; these can be ignored because they are treated the same as Runlevel 2 in Ubuntu. Historically, Ubuntu used the `/etc/inittab` file to handle runlevels, but with Upstart this file no longer exists. Instead there are several files under the `/etc/events.d/` directory, including an individual file for each of the virtual consoles (accessible by pressing Ctrl+Alt+F1 to F7). However, you are still able to create an inittab file, if you want to override any defaults held by Ubuntu. Make sure you create the inittab file as root and include at least one line similar to the following:

```
id:1:initdefault:
```

This will force your system to start up in text mode.

### Configuring Your Login Screen

The gdm display manager is part of the GNOME library and client distribution included with Ubuntu and provides a graphical login when a system boots directly to X. Its login hosts menus of window managers, languages, and system options for shutting down (halting) or rebooting the workstation. Although you can edit (as root) `gdm.conf` under the `/etc/gdm` directory to configure gdm, a much better way to configure GNOME’s display manager is to use the convenient GUI client.

You launch this client from the System Menu, under Administration, Login Screen. Click Unlock and you will be prompted for your password. Next, you see the Login Screen Settings window, as shown in Figure 3.4.

![Login Screen Settings](image-url)  
**FIGURE 3.4** Configuring GDM.
Here you can decide whether to play a login sound, show a list of users, show the screen for choosing who will log in, whether to allow a specific user to be logged in automatically at startup, and if so, whether to do so only after a delay of a specific number of seconds to allow someone else to log in, and what Ubuntu edition or desktop environment to use as the default session if you have more than one installed.

It is generally a good idea not to log anyone in automatically, but rather to require a user and password for log in, because you do not always know who will turn the machine on. I have a specific exception in my house on a computer set up for my kids to use. It automatically logs in to a very limited account filled with educational games, but no administrative access after a short ten second delay in case I am starting the computer and want to log in with my account and password to perform system maintenance.

**CAUTION**

We strongly recommend that you never set either of these two options unless you have an unimportant system containing no private or important data. It’s the equivalent of leaving your car unlocked, with the windows rolled down and signs around it reading “Steal Me.” Only if you fit a very special case should you use this, such as if you are creating a system that is designed to be used in a public access area, like as a kiosk, where it would not be unusual for some dimwit to turn the computer off every so often! In this scenario, you may not be available to log on to the system and may prefer it to default to the locked-down account that you created.

**Changing Window Managers**

Ubuntu makes it fairly painless to switch to another window manager or desktop environment. By *desktop environment*, we refer to not only the window manager but also the suite of related applications, such as productivity or configuration tools.

First, you need to ensure that you have the relevant desktop environment installed on your system; the easiest way to do this is by installing the relevant *-desktop package (as described earlier in the sidebar “The Ubuntu Family.” You can do this by installing the package kubuntu-desktop, for example (in the case of a KDE desktop); just search for desktop and look for Xubuntu or Kubuntu, and so on. After the download and installation is complete (you might want to grab a coffee while you wait, because these packages include a ton of dependencies and take some time to download, install, and configure), you are all set to change environments.

Next, you need to log out of Ubuntu. When you return to the log in page, select your name (as shown in Figure 3.5) and then use the bottom menu to select the session you want to use.

Here you can choose to switch your session to KDE (for example). It’s easy to change back should you not like your new environment. Chapter 8, “Other Ubuntu Desktops,” gives you a brief introduction to some of the desktop environments other than GNOME that are available from the Ubuntu repositories.
FIGURE 3.5 Use the Select Session option to select the desktop environment of your choice before you log in.

This page intentionally left blank
The Linux command line, sometimes called the terminal, is one of the most powerful tools available for computer system administration and maintenance. It is an efficient way to perform complex tasks accurately and much more easily than it would seem at a first glance. Knowledge of the commands available to you and also how to string them together will make using Ubuntu even easier for many tasks. Many of the commands were created by the GNU Project as free software analogs to previously existing proprietary UNIX commands. If you are interested, you can learn more about the GNU Project at www.gnu.org/gnu/thegnuproject.html.

This chapter looks at some of the basic commands that you need to know to be productive at the command line. You will find out how to get to the command line, and learn some of the commands used to navigate the file system. Later in the book we present a Command Line Masterclass (Chapter 30), which explores the subject in greater depth. The skills you learn in this chapter will help you get started using the command line with confidence.

**What Is the Command Line?**

If you spend any amount of time with experienced Linux users, you will hear them mention the command line. Some, especially those who have begun their journey in the Linux world using distributions, like Ubuntu, that make it easy to complete many tasks using a graphical user interface (GUI), may speak with trepidation about the mysteries of the text interface. Others will either praise its power or
comment about doing something via the command line as if it is the most natural and obvious way to complete a task.

It is not necessary for you to embrace either extreme. You may develop an affinity for the command line when performing some tasks and prefer the GUI for others. This is where most users end up today. Some may say that you will never need to access the command line because Ubuntu offers a slew of graphical tools that enable you to configure most things on your system. There are some good reasons to acquire a fundamental level of comfort with the command line that you should consider before embracing that view.

Sometimes things go wrong, and you may not have the luxury of a graphical interface to work with. In these situations, a fundamental understanding of the command line and its uses can be a real lifesaver. Also, some tasks end up being far easier and faster to accomplish from the command line.

**NOTE**

Don’t be tempted to skip over this chapter as irrelevant. You should take the time to work through the chapter and ensure that you are comfortable with the command line before moving on. Doing so will benefit you greatly for years to come.

Initially, some may be tempted to think of the command line as the product of some sort of black and arcane art, and in some ways it can appear to be extremely difficult and complicated to use. However, with a little perseverance, by the end of this chapter you will start to feel comfortable using the command line and you’ll be ready to move on to Chapter 35, “Command Line Masterclass.”

More importantly, though, you will be able to make your way around a command line–based system, which you are likely to encounter if you ever work with a Linux server since many Linux servers have no GUI and all administration is done using a command line interface via SSH.

This chapter introduces you to commands that enable you to do the following:

- **Perform routine tasks**—Logging in and out, changing passwords, listing and navigating file directories

- **Implement basic file management**—Creating files and folders, copying or moving them around the file system, renaming and deleting them

- **Execute basic system management**—Shutting down or rebooting, using text-based tools to edit system configuration files, and reading man pages, which are entries for commands included as files already on your computer in a standardized manual format

The information in this chapter is valuable for individual users or system administrators who are new to Linux and are learning to use the command line for the first time.
TIP

Those of you who have used a computer for many years will probably have come into contact with MS-DOS, in which case being presented with a black screen will fill you with a sense of nostalgia. Don’t get too comfy; the command line in Linux is different from (and actually more powerful than) its distant MS-DOS cousin. Even cooler is that, whereas MS-DOS skills are transferable only to other MS-DOS environments, the skills that you learn at the Linux command line can be transferred easily to other UNIX and UNIX-like operating systems, such as Solaris, OpenBSD, FreeBSD, and even Mac OS X, which provides access to the terminal.

USER ACCOUNTS

A good place to start is with the concept of user-based security. For the most part, only two types of people will access the system as users (although there will be other accounts that run programs and processes, here we are talking about accounts that represent human beings rather than something like an account created for a web server process). Most people have a regular user account. These users can change anything that is specific to their account, such as the wallpaper on the desktop, their personal preferences, the configuration for a program when it is run by them using their account, and so on. Note that the emphasis is on anything that is specific to them. This type of user is not able to make systemwide changes that could affect other users.

To make systemwide changes, you need to use super-user privileges, such as the account you created when you started Ubuntu for the first time (see Chapter 1, “Installing Ubuntu”). With super-user privileges you have access to the entire system and can carry out any task, even destructive ones! To help prevent this from happening, this user does not run with these powers enabled at all times, but instead spends most of the time with the look and feel of a regular user.

To use your super-user privileges from the command line you need to preface the command you want to execute with another command, sudo, followed by a space and the command you want to run. As a mnemonic device, some think of this as “super-user do.” When you press Enter (after typing the remaining command) you will be prompted for your password, which you should type in followed by the Enter key. As usual on any UNIX-based system, the password will not appear on the screen while you are typing it as a security measure, in case someone is watching over your shoulder. Ubuntu will then carry out the command, but with super-user privileges.
An example of the destructive nature of working as the super-user can be found in the age-old example, `sudo rm -rf /`, which erases everything on your hard drive. If you enter a command using `sudo` as a regular user who does not have an account with super-user privileges, an error message will appear and nothing will happen because the command will not run. We recommend that you don’t try this particular command as a test, though. If you enter this command using an account with super-user privileges, you will soon find yourself starting over with a fresh installation and hoping you have a current backup of all of your data. You need to be especially careful when using your super-user privileges; otherwise, you may do irreparable damage to your system.

However, the ability to work as the super-user is fundamental to a healthy Linux system and should not be feared, but rather respected and used only with focused attention. Without this ability you would not be able to install new software, edit system configuration files, or do a large number of important administration tasks. By the end of this chapter you will feel comfortable working with your super-user privileges and be able to adequately administer your system from the command line. By the way, you have already been performing operations with super-user privileges from the GUI if you have ever been asked to enter your password to complete a specific task, such as installing software updates. The difference is that most graphical interfaces limit the options that users have and make it a little more difficult to do some of the big, disruptive tasks, even the ones that are incredibly useful.

Ubuntu works slightly differently from many other Linux distributions. If you study some other Linux distros, especially older or more traditional ones, you will hear about a specific user account called root, which is a super-user account. In those distros, instead of typing in `sudo` before a command while using a regular user account with super-user privileges, you log in to the root account and simply issue the command without entering a password. In those cases, you can tell when you are using the root account at the command line because you will see a pound sign (`#`) in the command line prompt in the place of the dollar sign (`$`).

For example, `matthew@seymour:#` vs the usual `matthew@seymour:$`.

In Ubuntu the root account is disabled by default because forcing regular users with super-user privileges to type a specific command every time they want to execute a command as a super-user should have the benefit of making them carefully consider what they are doing when they use that power. It is easy to forget to log out of a root account, and entering a powerful command while logged in to root can be catastrophic. However, if you are more experienced and comfortable with the more traditional method of using super-user privileges and want to enable the root account, you can use the command `sudo passwd`. When prompted, enter your user password to confirm that your user account has super-user privileges. You will then be asked for a new UNIX password, which will be the password for the root account, so make sure and remember it. You will also be prompted to repeat the password, in case you’ve made any mistakes. After you’ve typed it in and pressed Enter, the root account will be active. You’ll find out how to switch to root later on.
An alternative way of getting a root prompt, without having to enable the root account, is to issue the command `sudo -i`. After entering your password you will find yourself at a root prompt (`#`). Do what you need to do and when you are finished, type `exit` and press Enter to return to your usual prompt. You can learn more about sudo and root from an Ubuntu perspective at https://help.ubuntu.com/community/RootSudo.

Ubuntu offers a number of ways to access the command line. One way is to press the key combination Ctrl+Alt+F1, after which Ubuntu will switch to a black screen and a login prompt like this:

```
Ubuntu 10.10 maverick seymour tty1
seymour login:
```

**TIP**

This is one of six virtual consoles that Ubuntu provides. After you have accessed a virtual console, you can use the Ctrl+Alt + any of F1 through F6 to switch to a different console. If you want to get back to the graphical interface, press Ctrl+Alt+ F7. You can also switch between consoles by holding the Alt key and pressing either the left or the right cursor key to move down or up a console, such as tty1 to tty2.

At the login prompt enter your username and press the Enter key. You will be asked for your password, which you should enter. Note that Ubuntu does not show any characters while you are typing your password in. This is a good thing because it prevents any shoulder surfers from seeing what you’ve typed or the length of the password.

Pressing the Enter key drops you to a shell prompt, signified by the dollar sign:

```
matthew@seymour:~$
```

This particular prompt tells me that I am logged in as the user matthew on the system seymour and I am currently in my home directory; Linux uses the tilde (~) as shorthand for the home directory, which would usually be something like `/home/matthew`.

**TIP**

Navigating through the system at the command line can get confusing at times, especially when a directory name occurs in several places. Fortunately, Linux includes a simple command that tells you exactly where you are in the file system. It’s easy to remember because the command is just an abbreviation of present working directory, so type `pwd` at any point to get the full path of your location. For example, typing `pwd` after following these instructions shows `/home/yourusername`, meaning that you are currently in your home directory.
Using the `pwd` command can save you a lot of frustration when you have changed directory half a dozen times and have lost track.

Another way to quickly access the terminal is to use the desktop menu option Applications, Accessories, Terminal. This opens up `gnome-terminal`, which allows you to access the terminal while remaining in a GUI environment. This time, the terminal appears as white text on an aubergine (dark purple) background. This is the most common method for most desktop users, but both are useful.

Regardless of which way you access the terminal, using the virtual tty consoles accessible at Ctrl + Alt + F1-6 or via the windowed version atop your GUI desktop, you will find the rest of the usage details that we cover work the same. As you continue to learn and experiment beyond the contents of this book, you may start to discover some subtle differences between the two and develop a preference. For our purposes, either method will work quite well.

With that, let’s begin.

**Navigating Through the File System**

Use the `cd` command to navigate the file system. This command is generally used with a specific directory location or pathname, like this:

```
matthew@seymour:~$ cd /etc/apt/
```

The `cd` command can also be used with several shortcuts. For example, to quickly move up to the *parent* directory, the one above the one you are currently in, use the `cd` command like this:

```
matthew@seymour:~$ cd ..
```

To return to your home directory from anywhere in the Linux file system, use the `cd` command like this:

```
matthew@seymour:~$ cd
```

You can also use the `$HOME` shell environment variable to accomplish the same thing. Type this command and press Enter to return to your home directory:

```
matthew@seymour:~$ cd $HOME
```

You can accomplish the same thing by using the tilde (~) like this:

```
matthew@seymour:~$ cd ~
```

Don’t forget you can always use `pwd` to remind you where you are within the file system!

The `ls` command lists the contents of the current directory. It’s commonly used by itself, but a number of options (also known as switches) are available for `ls` and give you more information. For instance, the following command returns a listing of all the files and directories within the current directory, including any hidden files (denoted by a . prefix) as well as a full listing, so it will include details such as the permissions, owner and group, size, and last modified time and date:

```
matthew@seymour:~$ ls -la
```
You can also issue the command

```
matthew@seymour:~$ ls -R
```

This command scans and lists all the contents of the subdirectories of the current directory. This might be a lot of information, so you may want to redirect the output to a text file so you can browse through it at your leisure by using the following:

```
matthew@seymour:~$ ls -laR > listing.txt
```

**TIP**

The previous command sends the output of `ls -laR` to a file called `listing.txt` and demonstrates part of the power of the Linux command line. At the command line you are able to use files as inputs to commands, or generate files as outputs as shown. For more information about combining commands, see Chapter 30. In the meantime, note that you can read the contents of that text file using the command `less listing.txt`, which will let you read the file bit by bit using the arrow keys to navigate in the file (or `Enter` to move to the next line), the spacebar to move to the next page, and `q` to exit when done.

Table 4.1 shows some of the top-level directories that are part of a standard Linux distro.

**TABLE 4.1 Basic Linux Directories**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/</td>
<td>The root directory</td>
</tr>
<tr>
<td>/bin</td>
<td>Essential commands</td>
</tr>
<tr>
<td>/boot</td>
<td>Boot loader files, Linux kernel</td>
</tr>

<tr>
<td>/root</td>
<td>Super-user (root) home</td>
</tr>
<tr>
<td>/sbin</td>
<td>System commands (mostly root only)</td>
</tr>
</tbody>
</table>
Knowing these directories can help you find files when you need them. This knowledge can even help you partition hard drives when you install new systems by letting you choose to put certain directories on their own distinct partition, which can be useful for things like isolating directories from one another, such as a server security case like putting a directory like `/boot` that doesn’t change often on its own partition and making it read-only and unchangeable without specific operations being done by a super-user during a maintenance cycle. Desktop users probably won’t need to think about that, but the directory tree is still quite useful to know when you want to find the configuration file for a specific program and set some program options systemwide to affect all users.

Some of the important directories in Table 4.1, such as those containing user and root commands or system configuration files, are discussed in the following sections. You may use and edit files under these directories when you use Ubuntu.

Linux also includes a number of commands you can use to search the file system. These include the following:

- `whereis command`—Returns the location of the command (e.g. `/bin`, `/sbin`, or `/usr/bin/`command) and its man page, which is an entry for the command included as a file already on your computer in a standardized manual format.

- `whatis command`—Returns a one-line synopsis from the command’s man page.

- `locate file`—Returns locations of all matching file(s); an extremely fast method of searching your system because `locate` searches a database containing an index of all files on your system. However, this database (which is several MB in size and named `mlocate.db`, under the `/var/lib/mlocate` directory) is built daily at 6:25 a.m. by default, and does not contain pathnames to files created during the workday or in the evening. If you do not keep your machine on constantly, you can run the `updatedb` command with super-user privileges to manually start the building of the database. More advanced users can change the time the database is updated by changing a `cron` job that calls the command. There is a script in `/etc/cron.daily` called `mlocate` that does this as part of the daily maintenance for the database. You would need to either remove that script from `/etc/cron.daily` and put it the root `crontab` or change when the daily tasks are run. If you don’t know how to do this right now, you should wait until you have read and understand Chapter 11,
“Automating Tasks,” and its discussion of cron, after which the preceding description will be clear.

- `apropos subject`—Returns a list of commands related to subject.
- `type name`—Returns how a name would be interpreted if used as a command. This generally shows options or the location of the binary that will be used. For example, `type ls` returns `ls is aliased to `ls -color=auto'.

### Managing Files with the Shell

Managing files in your home directory involves using one or more easily remembered commands. Basic file management operations include paging (reading), moving, renaming, copying, searching, and deleting files and directories. Here are some commands to do these tasks:

- `cat filename`—Outputs contents of filename to display
- `less filename`—Allows scrolling while reading contents of filename
- `mv file1 file2`—Renames file1 to file2 and may be used with full pathnames to move the file to a new directory at the same time
- `mv file dir`—Moves file to specified directory
- `cp file1 file2`—Copies file1 and creates file2
- `rm file`—Deletes file
- `rmdir dir`—Deletes directory (if empty)
- `grep string file(s)`—Searches through files(s) and displays lines containing matching string (a string is a series of characters like letters, numbers, and symbols, such as a word)

Note that each of these commands can be used with pattern-matching strings known as *wildcards* or *expressions*. For example, to delete all files in the current directory beginning with the letters abc, you can use an expression beginning with the first three letters of the desired filenames. An asterisk (*) is then appended to match all these files. Use a command line with the `rm` command like this:

```
matthew@seymour:~$ rm abc*
```

Linux shells recognize many types of filenaming wildcards, but this is different from the capabilities of Linux commands supporting the use of more complex expressions. You learn more about using wildcards in Chapter 11, “Automating Tasks.”

### NOTE

You can also learn more about using expressions by reading the grep manual pages (`man grep`).

Download from www.eBookTM.com
Working with Compressed Files

Another file management operation is compression and decompression of files, or the creation, listing, and expansion of file and directory archives. Linux distributions usually include several compression utilities you can use to create, compress, expand, or list the contents of compressed files and archives. These commands include:

- `bunzip2`—Expands a compressed file
- `bzip2`—Compresses or expands files and directories
- `gunzip`—Expands a compressed file
- `gzip`—Compresses or expands files and directories
- `tar`—Creates, expands, or lists the contents of compressed or uncompressed file or directory archives known as *tape archives* or *tarballs*

Most of these commands are easy to use. However, the `tar` command, which is the most commonly used of the bunch, has a somewhat complex set of command-line options and syntax. This flexibility and power are part of its popularity; you can quickly learn to use `tar` by remembering a few of the simple command line options. For example, to create a compressed archive of a directory, use `tar`’s `czf` options like this:

```
matthew@seymour:~$ tar czf dirname.tgz dirname
```

The result is a compressed archive (a file ending in `.tgz`) of the specified directory (and all files and directories under it). Add the letter `v` to the preceding options to view the list of files added during compression and archiving while the archive is being created. To list the contents of the compressed archive, substitute the `c` option with the letter `t`, like this:

```
matthew@seymour:~$ tar tzf archive
```

However, if many files are in the archive, a better invocation (to easily read or scroll through the output) is

```
matthew@seymour:~$ tar tzf archive | less
```

**TIP**

In the previous code example, we used a pipe character (`|`). Each pipe sends the output of the first command to the next command. This is another of the benefits of the command line under Linux—you can string several commands together to get the desired results.

To expand the contents of a compressed archive, use `tar`’s `zxf` options, like so:

```
matthew@seymour:~$ tar zxf archive
```
The `tar` utility decompresses the specified archive and extracts the contents in the current directory.

**Essential Commands from the `/bin` and `/sbin` Directories**

The `/bin` directory contains essential commands used by the system for running and booting the system. In general, only the root operator uses the commands in the `/sbin` directory. The software in both locations is essential to the system; they make the system what it is, and if they are changed or removed, it could cause instability or a complete system failure. Often, the commands in these two directories are *statically* linked, which means that the commands do not depend on software libraries residing under the `/lib` or `/usr/lib` directories. Nearly all the other applications on your system are *dynamically* linked—meaning that they require the use of external software libraries (also known as *shared* libraries) to run. This is a feature for both sets of software.

The commands in `/bin` and `/sbin` are kept stable to maintain foundational system integrity and do not need to be updated often, if at all. For the security of the system, these commands are kept in a separate location and isolated where changes are more difficult and where it will be more obvious to the system administrator if unauthorized changes are attempted or made.

Application software changes more frequently, and applications often use the same functions that other pieces of application software use. This was the genesis of shared libraries. When a security update is needed for something that is used by more than one program, it has to be updated in only one location, a specific software library. This enables easy and quick security updates that will affect several pieces of non-system-essential software at the same time by updating one shared library, contained in one file on the computer.

**Using and Editing Files in the `/etc` Directory**

System configuration files and directories reside under the `/etc` directory. Some major software packages, such as Apache, OpenSSH, and `xinetd`, have their own subdirectories in `/etc` filled with configuration files. Others like `crontab` or `fstab` use one file. Some examples of system-related configuration files in `/etc` include the following:

- **`fstab`**—The file system table is a text file listing each hard drive, CD-ROM, floppy, or other storage device attached to your PC. The table indexes each device’s partition information with a place in your Linux file system (directory layout) and lists other options for each device when used with Linux (see Chapter 36, “Kernel and Module Management”). Nearly all entries in `fstab` can be manipulated by root using the `mount` command.

- **`modprobe.d/`**—This folder holds all the instructions to load kernel modules that are required as part of the system startup.
• passwd—The list of users for the system, including special-purpose nonhuman users like syslog and couchdb, along with user account information.

• sudoers—A list of users or user groups with super-user access.

**Protecting the Contents of User Directories—/home**

The most important data on a Linux system resides in the user's directories, found under the /home directory. Segregating the system and user data can be helpful in preventing data loss and making the process of backing up easier. For example, having user data reside on a separate file system or mounted from a remote computer on the network might help shield users from data loss in the event of a system hardware failure. For a laptop or desktop computer at home, you might place /home on a separate partition from the rest of the file system, so that if the operating system is upgraded, damaged, or reinstalled, /home would be more likely to survive the event intact.

**Using the Contents of the /proc Directory to Interact with the Kernel**

The content of the /proc directory is created from memory and exists only while Linux is running. This directory contains special files that either extract information from or send information to the kernel. Many Linux utilities extract information from dynamically created directories and files under this directory, also known as a virtual file system. For example, the free command obtains its information from a file named meminfo:

```bash
matthew@seymour:~$ free

         total       used       free      shared   buffers     cached
Mem:      4055680     2725684    1329996   0        188996      1551464
-/+ buffers/cache:    985224     3070456
Swap:     8787512     0          8787512

matthew@seymour:~$ cat /proc/meminfo

MemTotal:                    4055680 KB
MemFree:                     1329996 KB
Buffers:                      189208 KB
Cached:                      1551488 KB
SwapCached:                        0 KB
Active:                      1222172 KB
Inactive:                    1192244 KB
Active(anon):                 684092 KB
Inactive(anon):                   16 KB
Active(file):                 538080 KB
Inactive(file):              1192228 KB
Unevictable:                      48 KB

SwapTotal:                   8787512 KB
```

This information constantly changes as the system is used. You can get the same information by using the cat command to see the contents of the meminfo file:

```bash
matthew@seymour:~$ cat /proc/meminfo

MemTotal:                    4055680 KB

The /proc directory can also be used to dynamically alter the behavior of a running Linux kernel by “echoing” numerical values to specific files under the /proc/sys directory. For example, to “turn on” kernel protection against one type of denial of service (DOS) attack known as SYN flooding, use the echo command to send the number 1 (one) to the following /proc path:

```
matthew@seymour:~$ sudo echo 1 >/proc/sys/net/ipv4/tcp_syncookies
```

Other ways to use the /proc directory include the following:

- Getting CPU information, such as the family, type, and speed from /proc/cpuinfo.
- Viewing important networking information under /proc/net, such as active interfaces information under /proc/net/dev, routing information in /proc/net/route, and network statistics in /proc/net/netstat.
- Retrieving file system information.
- Reporting media mount point information via USB; for example, the Linux kernel reports what device to use to access files (such as /dev/sda) if a USB camera or hard drive is detected on the system. You can use the dmesg command to see this information.
Getting the kernel version in `/proc/version`, performance information such as uptime in `/proc/uptime`, or other statistics such as CPU load, swap file usage, and processes in `/proc/stat`.

**Working with Shared Data in the `/usr` Directory**

The `/usr` directory contains software applications, libraries, and other types of shared data for use by anyone on the system. Many Linux system administrators give `/usr` its own partition. A number of subdirectories under `/usr` contain manual pages (`/usr/share/man`), software package shared files (`/usr/share/name_of_package, such as /usr/share/emacs`), additional application or software package documentation (`/usr/share/doc`), and an entire subdirectory tree of locally built and installed software, `/usr/local`.

**Temporary File Storage in the `/tmp` Directory**

As its name implies, the `/tmp` directory is used for temporary file storage; as you use Linux, various programs create files in this directory.

**Accessing Variable Data Files in the `/var` Directory**

The `/var` directory contains subdirectories used by various system services for spooling and logging. Many of these variable data files, such as print spooler queues, are temporary, whereas others, such as system and kernel logs, are renamed and rotated in use. Incoming electronic mail is usually directed to files under `/var/spool/mail`.

Linux also uses `/var` for other important system services. These include the top-most File Transfer Protocol (FTP) directory under `/var/ftp` (see Chapter 18, “Remote File Serving with FTP”), and the Apache web server's initial home page directory for the system, `/var/www/html`. (See Chapter 17, “Apache Web Server Management,” for more information on using Apache.)

**NOTE**

There is a recent trend to move data that is served from `/var/www` and `/var/ftp` to `/srv`, but this is not universal.

**Logging In to and Working with Linux**

You can access and use a Linux system in a number of ways. One way is at the console with a monitor, keyboard, and mouse attached to the PC. Another way is via a serial console, either by dial-up via a modem or a PC running a terminal emulator and connected to the Linux PC via a null modem cable. You can also connect to your system through a wired or wireless network, using the `telnet` or `ssh` commands. The information in this section shows you how to access and use the Linux system, using physical and remote text-based logins.
NOTE
This chapter focuses on text-based logins and use of Linux. Graphical logins and using a graphical desktop are described in Chapter 3, “Working with GNOME.”

Text-Based Console Login

If you sit down at your PC and log in to a Linux system that has not been booted to a graphical login, you see a prompt similar to this one:

```
Ubuntu 10.10 maverick seymour tty1
seymour login:
```

Your prompt might vary, depending on the version of Ubuntu you are using and the method you are using to connect. In any event, at this prompt, type in your username and press Enter. When you are prompted for your password, type it in and press Enter.

NOTE
Your password is not echoed back to you, which is a good idea. Why is it a good idea? Well, people are prevented from looking over your shoulder and seeing your screen input. It is not difficult to guess that a five-letter password might correspond to the user's spouse's first name!

Logging Out

Use the `exit` or `logout` command or Ctrl+D to exit your session. You are then returned to the login prompt. If you use virtual consoles, remember to exit each console before leaving your PC. (Otherwise, someone could easily sit down and use your account.)

Logging In and Out from a Remote Computer

Although you can happily log in on your computer, an act known as a local login, you can also log in to your computer via a network connection from a remote computer. Linux-based operating systems provide a number of remote access commands you can use to log in to other computers on your local area network (LAN), wide area network (WAN), or the Internet. Note that not only must you have an account on the remote computer, but the remote computer must be configured to support remote logins—otherwise, you won’t be able to log in.

NOTE
See Chapter 14, “Networking,” to see how to set up network interfaces with Linux to support remote network logins and Chapter 11 to see how to start remote access services (such as sshd).
The best and most secure way to log in to a remote Linux computer is to use ssh, the Secure Shell client. Your login and session are encrypted while you work on the remote computer. The ssh client features many command-line options, but can be simply used with the name or IP address of the remote computer, like this:

```
matthew@seymour:~$ ssh 192.168.0.41
The authenticity of host '192.168.0.41 (192.168.0.41)' can't be established.
Are you sure you want to continue connecting (yes/no)?

yes
```

The first time you connect with a remote computer using ssh, Linux displays the remote computer's encrypted identity key and asks you to verify the connection. After you type yes and press Enter, you are warned that the remote computer's identity (key) has been entered in a file named known_hosts under the .ssh directory in your home directory. You are also prompted to enter your password:

```
Warning: Permanently added '192.168.0.41' (RSA) to the list of known hosts.
matthew@192.168.0.41's password:
matthew@babbage~$
```

After entering your password, you can work on the remote computer, which you can confirm by noticing the changed prompt that now uses the name of the remote computer on which you are working. Again, because you are using ssh, everything you enter on the keyboard in communication with the remote computer is encrypted. When you log out, you will return to the shell on your computer.

```
matthew@babbage~$ logout
matthew@seymour:~$
```

**Using Environment Variables**

A number of in-memory variables are assigned and loaded by default when you log in. These variables are known as shell environment variables and can be used by various commands to get information about your environment, such as the type of system you are running, your home directory, and the shell in use. Environment variables are used to help tailor the computing environment of your system and include helpful specifications and setup, such as default locations of executable files and software libraries. If you begin writing shell scripts, you might use environment variables in your scripts. Until then, you need to be aware only of what environment variables are and do.

The following list includes a number of environment variables, along with descriptions of how the shell uses them:

- **PWD**—provides the full path to your current working directory, used by the `pwd` command, such as `/home/matthew/Documents`
Logging In to and Working with Linux

- **USER**—declares the user's name, such as `matthew`.
- **LANG**—sets the default language, such as English.
- **SHELL**—declares the name and location of the current shell, such as `/bin/bash`.
- **PATH**—sets the default location(s) of executable files, such as `/bin`, `/usr/bin`, and so on.
- **TERM**—sets the type of terminal in use, such as `vt100`, which can be important when using screen-oriented programs, such as text editors.

You can print the current value of any environment variable using `echo $VARIABLE-NAME`, like this:

```
matthew@seymour:~$ echo $USER
matthew
matthew@seymour:~$
```

**NOTE**

Each shell can have its own feature set and language syntax, as well as a unique set of default environment variables. See Chapter 15, “Remote Access for SSH and Telnet,” for more information about using the different shells included with Ubuntu.

You can use the `env` or `printenv` command to display all environment variables, like so:

```
matthew@seymour:~$ env
ORBIT_SOCKETDIR=/tmp/orbit-matthew
SSH_AGENT_PID=1729
TERM=vt100
SHELL=/bin/bash
WINDOWID=71303173
GNOME_KEYRING_CONTROL=/tmp/keyring-qTEFTw
GTK_MODULES=canberra-gtk-module
USER=matt
hew
SSH_AUTH_SOCK=/tmp/keyring-qTEFTw/ssh
DEFAULTS_PATH=/usr/share/gconf/gnome.default.path
SESSION_MANAGER=local/seymour:/tmp/.ICE-unix/1695
USERNAME=matthew
XDG_CONFIG_DIRS=/etc/xdg/xdg-gnome:/etc/xdg
DESKTOP_SESSION=gnome
DESKTOP_SESSION=gnome
PATH=/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin:/usr/games
PWD=/home/matt
hew
GDM_KEYBOARD_LAYOUT=us
LANG=en_US.utf8
```

Download from www.eBookTM.com
This abbreviated list shows some of the common variables. These variables are set by configuration or resource files contained in the /etc, /etc/skel, or user /home directory. You can find default settings for bash, for example, in /etc/profile and /etc/bashrc as well as .bashrc or .bash_profile files in your home directory. Read the man page for bash for details about using these configuration files.

One of the most important environment variables is $PATH, which defines the location of executable files. For example, if, as a regular user, you try to use a command that is not located in your $PATH (such as the imaginary command command), you will see something like this:

```
matthew@seymour:~$ command
-bash: command: command not found
```

If the command that you’re trying to execute exists in the Ubuntu software repositories, but is not yet installed on your system, Ubuntu will respond with the correct command to install the command.

```
matthew@seymour:~$ command

The program 'command' is currently not installed. You can install it by typing:

```
sudo apt-get install command
```

However, you might know that command is definitely installed on your system, and you can verify this by using the whereis command, like so:

```
$ whereis command
command: /sbin/command
```
You can also run the command by typing its full pathname or complete directory specification, like this:

```
$ /sbin/command
```

As you can see in this example, the command `command` is indeed installed. What happened is that by default, the `/sbin` directory is not in your `$PATH`. One of the reasons for this is that commands under the `/sbin` directory are normally intended to be run only by root.

You can add `/sbin` to your `$PATH` by editing the file `.bash_profile` in your home directory (if you use the bash shell by default, like most Linux users). Look for the following line:

```
PATH=$PATH:$HOME/bin
```

You can then edit this file, perhaps using the `vi` editor (discussed later in this chapter), to add the `/sbin` directory like so:

```
PATH=$PATH:/sbin:$HOME/bin
```

Save the file. The next time you log in, the `/sbin` directory is in your `$PATH`. One way to use this change right away is to read in the new settings in `.bash_profile` by using the bash shell's source command like so:

```
$ source .bash_profile
```

You can now run commands located in the `/sbin` directory without the need to explicitly type the full pathname.

Some Linux commands also use environment variables, for example, to acquire configuration information (such as a communications program looking for a variable such as `BAUD_RATE`, which might denote a default modem speed).

To experiment with the environment variables, you can modify the `PS1` variable to manipulate the appearance of your shell prompt. If you are working with `bash`, you can use its built-in `export` command to change the shell prompt. For example, if your default shell prompt looks like this:

```
matthew@seymour:~$
```

You can change its appearance by using the `PS1` variable like this:

```
$ PS1='$OSTYPE r00lz ->'
```

After you press Enter, you see

```
linux-gnu r00lz ->
```

**NOTES**

See the bash man page for other variables you can use for prompt settings.
Using the Text Editors

Linux distributions include a number of applications known as text editors that you can use to create text files or edit system configuration files. Text editors are similar to word processing programs, but generally have fewer features, work only with text files, and might or might not support spell checking or formatting. Text editors range in features and ease of use and are found on nearly every Linux distribution. The number of editors installed on your system depends on what software packages you’ve installed on the system.

Some of the more popular console-based text editors include:

- **emacs**—The comprehensive GNU emacs editing environment, which is much more than an editor; see the section “Working with emacs” later in this chapter.
- **joe**—Joe’s Own Editor, a text editor, which can be used to emulate other editors.
- **nano**—A simple text editor similar to the pico text editor included with the pine email program.
- **vim**—An improved, compatible version of the vi text editor (which we call vi in the rest of this chapter because it has a symbolic link named vi and a symbolically linked manual page).

Note that not all text editors are screen oriented, meaning designed for use from a terminal. Some of the text editors are designed to run from a graphical desktop and which provide a graphical interface with menu bars, buttons, scrollbars, and so on, are:

- **gedit**—A GUI text editor for GNOME
- **kate**—A simple KDE text editor
- **kedit**—Another simple KDE text editor

A good reason to learn how to use a text-based editor, such as vi or nano, is that system maintenance and recovery operations almost never take place during X Window sessions, negating the use of a GUI editor. Many larger, more complex and capable editors do not work when Linux is booted to its single-user or maintenance mode. If anything does go wrong with your system and you can’t log into the X Window system and its graphical user interface, knowledge and experience of using both the command line and text editors will turn out to be very important. Make a point of opening some of the editors and playing around with them; you never know—you might just thank me someday!

Another reason to learn how to use a text-based editor under the Linux console mode is so that you can edit text files through remote shell sessions, because many servers will not host graphical desktops.

**Working with vi**

The one editor found on nearly every UNIX and Linux system is the vi editor, originally written by Bill Joy. This simple-to-use but incredibly capable editor features a somewhat cryptic command set, but you can put it to use with only a few commands. Although many experienced UNIX and Linux users use vi extensively during computing sessions,
many users who do only quick and simple editing might not need all its power and may prefer an easier-to-use text editor such as *pico* or GNU *nano*. Diehard GNU fans and programmers definitely use *emacs*.

However, learning how to use *vi* is a good idea. You might need to edit files on a Linux system with a minimal install, or a remote server without a more extensive offering of installed text editors. Chances are nearly 100 percent that *vi* will be available.

You can start an editing session by using the *vi* command like this:

```
matthew@seymour:$ vi file.txt
```

The *vi* command works by using an insert (or editing) mode, and a viewing (or command) mode.

When you first start editing, you are in the viewing mode. You can use your arrow or other navigation keys (as shown later) to scroll through the text. To start editing, press the *i* key to insert text or the *a* key to append text. When you’re finished, use the *Esc* key to toggle out of the insert or append modes and into the viewing (or command) mode. To enter a command, type a colon (:), followed by the command, such as *w* to write the file, and press Enter.

Although *vi* supports many complex editing operations and numerous commands, you can accomplish work by using a few basic commands. These basic *vi* commands are

- **Cursor movement**—h, j, k, l (left, down, up, and right)
- **Delete character**—x
- **Delete line**—dd
- **Mode toggle**—Esc, Insert (or i)
- **Quit**—:q
- **Quit without saving**—:q!
- **Run a shell command**—:sh (use 'exit' to return)
- **Save file**—:w
- **Text search**—/

**NOTE**

Use the *vimtutor* command to quickly learn how to use *vi*’s keyboard commands. The tutorial takes less than 30 minutes, and it teaches new users how to start or stop the editor, navigate files, insert and delete text, and perform search, replace, and insert operations.

### Working with *emacs*

Richard M. Stallman’s GNU *emacs* editor, like *vi*, is included with Ubuntu and nearly every other Linux distribution. Unlike other UNIX and Linux text editors, *emacs* is much more than a simple text editor—it is an editing environment and can be used to compile...
and build programs and act as an electronic diary, appointment book, and calendar; use it to compose and send electronic mail, read Usenet news, and even play games. The reason for this capability is that emacs contains a built-in language interpreter that uses the Elisp (emacs LISP) programming language. emacs is not installed in Ubuntu by default. To use emacs, the package you need to install is called emacs. See Chapter 32, “Managing Software.”

You can start an emacs editing session like this:

```
matthew@seymour:~$ emacs file.txt
```

**TIP**

If you start emacs when using X11, the editor launches in its own floating window. To force emacs to display inside a terminal window instead of its own window (which can be useful if the window is a login at a remote computer), use the `-nw` command-line option like this: `emacs -nw file.txt`.

The emacs editor uses an extensive set of keystroke and named commands, but you can work with it by using a basic command subset. Many of these basic commands require you to hold down the Ctrl key, or to first press a meta key (generally mapped to the Alt key). The basic commands are listed in Table 4.2.

<table>
<thead>
<tr>
<th>Action</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abort</td>
<td>Ctrl+G</td>
</tr>
<tr>
<td>Cursor left</td>
<td>Ctrl+B</td>
</tr>
<tr>

<td>Ctrl+X, Ctrl+W</td>
</tr>
<tr>
<td>Save file</td>
<td>Ctrl+X, Ctrl+S</td>
</tr>
</tbody>
</table>
Working with Permissions

Under Linux (and UNIX), everything in the file system, including directories and devices, is a file. And every file on your system has an accompanying set of permissions based on ownership. These permissions provide data security by giving specific permission settings to every single item denoting who may read, write, and/or execute the file. These permissions are set individually for the file’s owner, for members of the group the file belongs to, and for all others on the system.

You can examine the default permissions for a file you create by using the umask command, which lists default permissions using the number system explained next, or by using the touch command and then the ls command’s long-format listing like this:

```
matthew@seymour:$ touch file
matthew@seymour:$ ls -l file
-rw-r--r-- 1 matthew matthew 0 2010-06-30 13:06 file
```

In this example, the touch command is used to quickly create a file. The ls command then reports on the file, displaying the following (from left to right):

- **The type of file created**—Common indicators of the type of file are in the leading letter in the output. A blank (which is represented by a dash, as in the preceding example) designates a plain file, d designates a directory, c designates a character device (such as /dev/ttyS0), and b is used for a block device (such as /dev/sda).
- **Permissions**—Read, write, and execute permissions for the owner, group, and all others on the system. (You learn more about these permissions later in this section.)
- **Number of links to the file**—The number one (1) designates that there is only one file, whereas any other number indicates that there might be one or more hard-linked
files. Links are created with the `ln` command. A hard-linked file is an exact copy of the file, but it might be located elsewhere on the system. Symbolic links of directories can also be created, but only the root operator can create a hard link of a directory.

- **The owner**—The account that owns the file; this is originally the file creator, but you can change this designation using the `chown` command.

- **The group**—The group of users allowed to access the file; this is originally the file creator’s main group, but you can change this designation using the `chgrp` command.

- **File size and creation/modification date**—The last two elements indicate the size of the file in bytes and the date the file was created or last modified.

### Assigning Permissions

Under Linux, permissions are grouped by owner, group, and others, with read, write, and execute permission assigned to each, like so:

<table>
<thead>
<tr>
<th>Owner</th>
<th>Group</th>
<th>Others</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rwx</td>
<td>rwx</td>
<td>rwx</td>
</tr>
</tbody>
</table>

Permissions can be indicated by mnemonic or octal characters. Mnemonic characters are

- `r` indicates permission for an owner, member of the owner’s group, or others to open and read the file.

- `w` indicates permission for an owner, member of the owner’s group, or others to open and write to the file.

- `x` indicates permission for an owner, member of the owner’s group, or others to execute the file (or read a directory).

In the previous example for the file named `file`, the owner, `matthew`, has read and write permission. Any member of the group named `matthew` may only read the file. All other users may only read the file. Also note that default permissions for files created by the root operator (while using sudo or a root account) will be different because of `umask` settings assigned by the shell.

Many users prefer to use numeric codes, based on octal (base 8) values, to represent permissions. Here’s what these values mean:

- 4 indicates read permission.

- 2 indicates write permission.

- 1 indicates execute permission.

In octal notation, the previous example file has a permission setting of 664 (read + write or 4 + 2, read + write or 4 + 2, read-only or 4). Although you can use either form of permissions notation, octal is easy to use quickly after you visualize and understand how permissions are numbered.
In Linux, you can create groups to assign a number of users access to common directories and files, based on permissions. You might assign everyone in accounting to a group named accounting and allow that group access to accounts payable files while disallowing access by other departments. Defined groups are maintained by the root operator, but you can use the newgrp command to temporarily join other groups to access files (as long as the root operator has added you to the other groups). You can also allow or deny other groups’ access to your files by modifying the group permissions of your files.

### Directory Permissions

Directories are also files under Linux. For example, again use the `ls` command to show permissions like this:

```
matthew@seymour:~$ mkdir directory
matthew@seymour:~$ ls -ld directory
drwxr-xr-x 2 matthew matthew 4096 2010-06-30 13:23 directory
```

In this example, the `mkdir` command is used to create a directory. The `ls` command and its `-ld` option is used to show the permissions and other information about the directory (not its contents). Here you can see that the directory has permission values of 755 (read + write + execute or 4 + 2 + 1, read + execute or 4 + 1, and read + execute or 4 + 1).

This shows that the owner can read and write to the directory and, because of execute permission, also list the directory’s contents. Group members and all other users can list only the directory contents. Note that directories require execute permission for anyone to be able to view their contents.

You should also notice that the `ls` command’s output shows a leading `d` in the permissions field. This letter specifies that this file is a directory; normal files have a blank field in its place. Other files, such as those specifying a block or character device, have a different letter.

For example, if you examine the device file for a Linux serial port, you will see:

```
matthew@seymour:~$ ls -l /dev/ttyS0
crw-rw---- 1 root dialout 4, 64 2010-06-30 08:13 /dev/ttyS0
```

Here, `/dev/ttyS0` is a character device (such as a serial communications port and designated by a `c`) owned by root and available to anyone in the `dialout` group. The device has permissions of 660 (read + write, read + write, no permission).

On the other hand, if you examine the device file for an IDE hard drive, you see:

```
matthew@seymour:~$ ls -l /dev/sda
brw-rw---- 1 root disk 8, 0 2010-06-30 08:13 /dev/sda
```
In this example, `b` designates a block device (a device that transfers and caches data in blocks) with similar permissions. Other device entries you will run across on your Linux system include symbolic links, designated by `s`.

You can use the `chmod` command to alter a file’s permissions. This command uses various forms of command syntax, including octal or a mnemonic form (such as `u`, `g`, `o`, or `a` and `rwx`, and so on) to specify a desired change. The `chmod` command can be used to add, remove, or modify file or directory permissions to protect, hide, or open up access to a file by other users (except for the root account or a user with super-user permission and using `sudo`, either of which can access any file or directory on a Linux system).

The mnemonic forms of `chmod`'s options are (when used with a plus character, `+`, to add, or a minus sign, `-`, to remove):

- `u`—Adds or removes user (owner) read, write, or execute permission
- `g`—Adds or removes group read, write, or execute permission
- `o`—Adds or removes read, write, or execute permission for others not in a file’s group
- `a`—Adds or removes read, write, or execute permission for all users
- `r`—Adds or removes read permission
- `w`—Adds or removes write permission
- `x`—Adds or removes execution permission

For example, if you create a file, such as a `readme.txt`, the file will have default permissions (set by the `umask` setting in `/etc/bashrc`) of

```
-rw-r--r-- 1 matthew matthew 0 2010-06-30 13:33 readme.txt
```

As you can see, you can read and write the file. Anyone else can only read the file (and only if it is outside your home directory, which will have read, write, and execute permission set only for you, the owner). You can remove all write permission for anyone by using `chmod`, the minus sign, and `aw` like so:

```
matthew@seymour:~$ chmod a-w readme.txt
matthew@seymour:~$ ls -l readme.txt
-r--r--r-- 1 matthew matthew 0 2010-06-30 13:33 readme.txt
```

Now, no one can write to the file (except you, if the file is in your home or `/tmp` directory because of directory permissions). To restore read and write permission for only you as the owner, use the plus sign and the `u` and `rw` options like so:

```
matthew@seymour:~$ chmod u+rw readme.txt
matthew@seymour:~$ ls -l readme.txt
-rw-r--r-- 1 matthew matthew 0 2010-06-30 13:33 readme.txt
```

Download from www.eBookTM.com
You can also use the octal form of the chmod command, for example, to modify a file's permissions so that only you, the owner, can read and write a file. Use the chmod command and a file permission of 600, like this:

```
matthew@seymour:-$ chmod 600 readme.txt
matthew@seymour:-$ ls -l readme.txt
-rw------- 1 matthew matthew 0 2010-06-30 13:33 readme.txt
```

If you take away execution permission for a directory, files might be hidden inside and may not be listed or accessed by anyone else (except the root operator, of course, who has access to any file on your system). By using various combinations of permission settings, you can quickly and easily set up a more secure environment, even as a normal user in your home directory.

### Understanding Set User ID and Set Group ID Permissions

Two more types of permission are “set user ID”, known as suid, and “set group ID,” or sgid, permissions. These settings, when used in a program, enable any user running that program to have program owner or group owner permissions for that program. These settings enable the program to be run effectively by anyone, without requiring that each user’s permissions be altered to include specific permissions for that program.

One commonly used program with suid permissions is the passwd command:

```
matthew@seymour:-$ ls -l /usr/bin/passwd
-rwsr-xr-x 1 root root 42856 2010-01-26 10:09 /usr/bin/passwd
```

This setting allows normal users to execute the command (as root) to make changes to a root-only accessible file, /etc/passwd.

You also can assign similar permission with the chfn command. This command allows users to update or change finger information in /etc/passwd. You accomplish this permission modification by using a leading 4 (or the mnemonic s) in front of the three octal values.

**NOTE**

Other files that might have suid or guid permissions include at, rcp, rlogin, rsh, chage, chsh, ssh, crontab, sudo, sendmail, ping, mount, and several UNIX-to-UNIX Copy (UUCP) utilities. Many programs (such as games) might also have this type of permission to access a sound device.

Files or programs that have suid or guid permissions can sometimes present security holes because they bypass normal permissions. This problem is compounded if the permission extends to an executable binary (a command) with an inherent security flaw because it could lead to any system user or intruder gaining root access. In past exploits, this typically happened when a user fed a vulnerable command with unexpected input (such as a...
long pathname or option); the command would fail, and the user would be presented a root prompt. Although Linux developers are constantly on the lookout for poor programming practices, new exploits are found all the time, and can crop up unexpectedly, especially in newer software packages that haven’t had the benefit of peer developer review.

Savvy Linux system administrators keep the number of suid or guid files present on a system to a minimum. The find command can be used to display all such files on your system:

```bash
matthew@seymour:~$ sudo find / -type f -perm /6000 -exec ls -l {} \;
```

**NOTE**

The find command is quite helpful and can be used for many purposes, such as before or during backup operations. See the section “Using Backup Software” in Chapter 13, “Backing Up.”

Note that the programs do not necessarily have to be removed from your system. If your users really do not need to use the program, you can remove the programs execute permission for anyone. You have to decide, as the root operator, whether your users are allowed, for example, to mount and unmount CD-ROMs or other media on your system. Although Linux-based operating systems can be set up to accommodate ease of use and convenience, allowing programs such as `mount` to be suid might not be the best security policy. Other candidates for suid permission change could include the `chsh`, `at`, or `chage` commands.

**Working as Root**

The root, or super-user account, is a special account and user on UNIX and Linux systems. Super-user permissions are required in part because of the restrictive file permissions assigned to important system configuration files. You must have root permission to edit these files or to access or modify certain devices (such as hard drives). When logged in as root, you have total control over your system, which can be dangerous.

When you work in root, you can destroy a running system with a simple invocation of the `rm` command like this:

```bash
matthew@seymour:~$ sudo rm -rf /
```

This command line not only deletes files and directories, but also could wipe out file systems on other partitions and even remote computers. This alone is reason enough to take precautions when using root access.

The only time you should run Linux as the super-user is when you are configuring the file system, for example, or to repair or maintain the system. Logging in and using Linux as the root operator isn’t a good idea because it defeats the entire concept of file permissions.
Knowing how to run commands as the super-user (root) without logging in as root can help avoid serious missteps when configuring your system. In Ubuntu, you can use `sudo` to allow you to execute single commands as root and then quickly return to normal user status. For example, if you would like to edit your system’s file system table (a simple text file that describes local or remote storage devices, their type, and location), you can use `sudo` like this:

```bash
matthew@seymour:~$ sudo nano -w /etc/fstab
Password:
```

After you press Enter, you are prompted for a password that gives you access to root. This extra step can also help you “think before you leap” into the command. Enter the root password, and you are then editing `/etc/fstab`, using the nano editor with line wrapping disabled (thanks to the `-w`).

**CAUTION**

Before editing any important system or software service configuration file, make a backup copy. Then make sure to launch your text editor with line wrapping disabled. If you edit a configuration file without disabling line wrapping, you could insert spurious carriage returns and line feeds into its contents, causing the configured service to fail when restarting. By convention, nearly all configuration files are formatted for 80-character text width, but this is not always the case. By default, the `vi` and `emacs` editors don’t use line wrap.

**Creating Users**

When a Linux system administrator creates a user, an entry in `/etc/passwd` for the user is created. The system also creates a directory, labeled with the user’s username, in the `/home` directory. For example, if you create a user named heather, the user’s home directory is `/home/heather`.

**NOTE**

In this chapter, you learn how to manage users from the command line. See Chapter 10, “Managing Users,” for more information on user administration with Ubuntu using graphical administration utilities, such as the graphical `users-admin` client found in the menu at System, Administration, Users and Groups.

Use the `useradd` command, along with a user’s name, to quickly create a user:

```bash
matthew@seymour:~$ sudo useradd ryan
```
After creating the user, you must also create the user's initial password with the `passwd` command:

```
matthew@seymour:-$ sudo passwd ryan
```

Changing password for user ryan.
New password:
Retype new password:
passwd: all authentication tokens updated successfully.

Enter the new password twice. If you do not create an initial password for a new user, the user cannot log in.

You can view `useradd`'s default new user settings by using the command and its `-D` option, like this:

```
matthew@seymour:-$ useradd -D
GROUP=100
HOME=/home
INACTIVE=-1
EXPIRE=
SHELL=/bin/sh
SKELETC/skel
CREATE_MAIL_SPOOL=no
```

These options display the default group ID, home directory, account and password policy (active forever with no password expiration), the default shell, and the directory containing defaults for the shell.

The `useradd` command has many command-line options. The command can be used to set policies and dates for the new user's password, assign a login shell, assign group membership, and other aspects of a user's account. See `man useradd` for more info.

**Deleting Users**

Use the `userdel` command to delete users from your system. This command removes a user's entry in the system's `/etc/passwd` file. You should also use the command's `-r` option to remove all the user's files and directories (such as the user's mail spool file under `/var/spool/mail`):

```
matthew@seymour:-$ sudo userdel -r andrew
```

If you do not use the `-r` option, you have to manually delete the user's directory under `/home`, along with the user's `/var/spool/mail` queue.
Shutting Down the System

Use the shutdown command to shut down your system. The shutdown command has a number of different command-line options (such as shutting down at a predetermined time), but the fastest way to cleanly shut down Linux is to use the -h or halt option, followed by the word now or the numeral zero (0), like this:

```
matthew@seymour:~$ sudo shutdown -h now
```

or

```
matthew@seymour:~$ sudo shutdown -h 0
```

To incorporate a timed shutdown and a pertinent message to all active users, use shutdown's time and message options, like so:

```
matthew@seymour:~$ sudo shutdown -h 18:30 "System is going down for maintenance this evening at 6:30 p.m. Please make sure you have saved your work and logged out by then or you may lose data."
```

This example shuts down your system and provides a warning to all active users 15 minutes before the shutdown (or reboot). Shutting down a running server can be considered drastic, especially if there are active users or exchanges of important data occurring (such as a backup in progress). One good approach is to warn users ahead of time. This can be done by editing the system Message of the Day (MOTD) motd file, which displays a message to users when they login using the command line interface, as is common on multi-user systems.

It used to be that to create a custom MOTD you only had to use a text editor and change the contents of /etc/motd. However, this has changed in Ubuntu as the developers have added a way to automatically and regularly update some useful information contained in MOTD using cron. To modify how the MOTD is updated, you should install update-motd and read the man page.

You can also make downtimes part of a regular schedule, perhaps to coincide with security audits, software updates, or hardware maintenance.

You should shut down Ubuntu for only a few very specific reasons:

- You are not using the computer, no other users are logged in or expected to need or use the system, such as your personal desktop or laptop computer, and you want to conserve electrical power.
- You need to perform system maintenance that requires any or all system services to be stopped.
- You want to replace integral hardware.
TIP

Do not shut down your computer if you suspect that one or more intruders has infiltrated your system; instead, disconnect the machine from any or all networks and make a backup copy of your hard drives. You might want to also keep the machine running to examine the contents of memory and to examine system logs. Exceptions to this are when the system contains only trivial data files and non-essential services, such as a personal computer that is only used to run a web browser, and when you have no intention of trying to track down what an intruder may have changed, either to repair the damage or to try to catch them using computer forensics, but rather plan to merely wipe everything clean and rebuild or reinstall the system from scratch.

Rebooting the System

You should also use the `shutdown` command to reboot your system. The fastest way to cleanly reboot Linux is to use the `–r` option, and the word `now` or the numeral zero (`0`):

```
matthew@seymour:~$ sudo shutdown -r now
```

or

```
matthew@seymour:~$ sudo shutdown -r 0
```

Both rebooting and shutting down can have dire consequences if performed at the wrong time (such as during backups or critical file transfers, which arouses the ire of your system’s users). However, Linux-based operating systems are designed to properly stop active system services in an orderly fashion. Other commands you can use to shut down and reboot Linux are the `halt` and `reboot` commands, but the `shutdown` command is more flexible.

Reading Documentation

Although you learn the basics of using Ubuntu in this book, you need time and practice to master and troubleshoot more complex aspects of the Linux operating system and your distribution. As with any operating system, you can expect to encounter some problems or perplexing questions as you continue to work with Linux. The first place to turn for help with these issues is the documentation included with your system; if you cannot find the information you need there, check Ubuntu’s website.

Using Apropos

Linux, like UNIX, is a self-documenting system, with man pages accessible through the `man` command. Linux offers many other helpful commands for accessing its documentation. You can use the `apropos` command—for example, with a keyword such as `partition`—to find commands related to partitioning, like this:

```
matthew@seymour:~$ apropos partition
addpart       (8)    - Simple wrapper around the "add partition" ioctl
all-swaps     (7)    - Event signaling that all swap partitions have been ac...
```
To find a command and its documentation, you can use the `whereis` command. For example, if you are looking for the `fdisk` command, you can do this:

```
$ whereis fdisk
fdisk: /sbin/fdisk /usr/share/man/man8/fdisk.8.gz
```

### Using Man Pages

To learn more about a command or program, use the `man` command, followed by the name of the command. Man pages are stored in places like `/usr/share/man` and `/usr/local/share/man`, but you don't need to know that. To read a man page, such as the one for the `rm` command, use the `man` command like this:

```
matthew@seymour:~$ man rm
```

After you press Enter, the less command (a Linux command known as a *pager*) displays the man page. The less command is a text browser you can use to scroll forward and backward (even sideways) through the document to learn more about the command. Type the letter `h` to get help, use the forward slash to enter a search string, or press `q` to quit.

### NOTE

Nearly all the hundreds of commands included with Linux each have a man page; however, some do not or may only have simple pages. You may also use the `info` command to read more detailed information about some commands or as a replacement for others. For example, to learn even more about `info` (which has a rather extensive manual page), use the `info` command like this:

```
$ info info
```

Use the arrow keys to navigate through the document and press `q` to quit reading.

The following programs and built-in shell commands are commonly used when working at the command line. These commands are organized by category to help you understand the command's purpose. If you need to find full information for using the command, you can find that information under the command's man page.
Managing users and groups—chage, chfn, chsh, edquota, gpasswd, groupadd, groupdel, groupmod, groups, mkpasswd, newgrp, newusers, passwd, umask, useradd, userdel, usermod

Managing files and file systems—cat, cd, chattr, chmod, chown, compress, cp, dd, fdisk, find, gzip, ln, mkdir, mkfs, mount, mv, rm, rmdir, rpm, sort, swapon, swapoff, tar, touch, umount, uncompress, uniq, unzip, zip

Managing running programs—bg, fg, kill, killall, nice, ps, pstree, renice, top, watch

Getting information—apropos, cal, cat, cmp, date, diff, df, dir, dmesg, du, env, file, free, grep, head, info, last, less, locate, lsattr, man, more, pinfo, ps, pwd, stat, strings, tac, tail, top, uname, uptime, vdir, vmstat, w, wc, whatis, whereis, which, who, whoami

Console text editors—ed, jed, joe, mcedit, nano, red, sed, vim

Console Internet and network commands—bing, elm, ftp, host, hostname, ifconfig, links, lynx, mail, mutt, ncftp, netconfig, netstat, pine, ping, pump, rdate, route, scp, sftp, ssh, tcpdump, traceroute, whois, wire-test

The Internet is everywhere. From cell phones to offices, from game consoles to iPads, we are surrounded by multiple access routes to online information and communication. Ubuntu is no outsider when it comes to accessing information through the Internet; it comes equipped with all the tools you need to connect to other people across the globe.

In this chapter we’ll take a look at some of the popular Internet applications that are available with Ubuntu. You’ll find out about Firefox and the new option, Google Chrome. We’ll also investigate some of the email clients available. Other topics include RSS feed readers, Instant Messaging (through IRC and other networks), and reading newsgroups.

A BRIEF INTRODUCTION TO THE INTERNET

The Internet itself was first brought to life by the U.S. Department of Defense in 1969. It was called ARPANET after the Department of Defense’s Advanced Research Projects Agency. Designed to build a network that would withstand major catastrophe (this was the peak of the Cold War), it soon grew to encompass more and more networks to build the Internet. Then, in 1991, Tim Berners-Lee of CERN developed the idea of the World Wide Web, including Hypertext Transfer Protocol (HTTP) and Hypertext Markup Language (HTML). This gave us what we now know to be the Internet.
Getting Started with Firefox

One of the most popular web browsers, and in fact the default web browser in Ubuntu, is Mozilla Firefox (see Figure 5.1). Built on a solid code base that is derived from the Mozilla Suite, Firefox offers an open source and more secure alternative to surfing the Internet using Internet Explorer, regardless of your operating system.

Beyond the basic program are a wealth of plug-ins and extensions that can increase the capabilities of Firefox beyond simple web browsing. Plug-ins such as Shockwave, Flash, and Java are available for installation instantly, offered to you when first needed, as are multimedia codecs for viewing video content. Extensions provide useful additions to the browsing experience. For example, ForecastFox is an extension that gives you your local weather conditions, and Bandwidth Tester is a tool that calculates your current bandwidth. As Firefox grows, there will be more and more extensions and plug-ins that you can use to enhance your browsing pleasure.

You can find and obtain these plug-ins and extensions easily because Mozilla developers have created a site dedicated to helping you get more from Firefox. You don't have to
search to find the site as there is a link in the Firefox menu at Tools, Add-ons, Get Add-ons that takes you directly to it. Particular favorites are the Adblock Plus and the StumbleUpon plug-ins. Adblock Plus allows you to nuke all those annoying banners and animations that take up so much bandwidth while you are browsing. StumbleUpon is a neat plug-in that takes you to web pages based on your preferences. Be warned, though, that StumbleUpon can be quite addictive, and you will end up wasting away many hours clicking the stumble button!

**FLASH**

You can easily enable Flash in your browser by installing the `flashplugin-installer` package or better yet, you can deal with the whole issue of codecs and functionality for your entire operating system right off by installing `ubuntu-restricted-extras`. Either way, Ubuntu will download the official package from Adobe and install it on your system. A browser restart is required before you try to access any Flash-enabled content.

To make things even easier, if you have not yet installed this package and visit a web page that requires flash, a pop up window will appear with information and a link to help you install it easily.

Another plug-in that we make a lot of use of is Xmarks. If, like us, you work across multiple computers and operating systems, you will no doubt have had to re-create bookmarks at every different computer and try to keep them the same. Xmarks makes this whole process much easier by allowing you to synchronize your bookmarks to multiple browsers (for example, Firefox and Google Chrome) running on different operating systems (Windows, Mac OS X, Linux).

**Checking Out Google Chrome and Chromium**

Anyone who has been paying attention to tech news over the last year has heard about the explosive appearance of Google Chrome (Figure 5.2). This new browser is fast, secure, expandable with extensions, and the hottest new toy on geek desktops. It is based on WebKit and other technologies, and it downloads and renders quickly while being standards compliant. You can learn more about the easy installation of Google Chrome at www.google.com/chrome?platform=linux.

Chrome is not a completely open source, but the main foundational parts are made available as Google Chromium, shown in Figure 5.3, which has most of the functionality of Chrome, but it is missing the Google branding, automatic updates, and is used as the test and development foundation for Chrome releases. As a point of interest, chromium is the metal from which chrome is made, hence the names.

You can learn more about Chromium at http://code.google.com/chromium/. It used to be necessary to install Chromium from the Google website or from the Personal Package Archive of the Google Chromium developers. Now, you may simply install chromium-browser from the Ubuntu repositories.
Choosing an Email Client

Back in the earlier days of UNIX there were various text-based email clients such as elm and pine (Pine Is Not Elm). Although they looked basic, they allowed the average user to interact with email, both for composing and reading correspondence, and had some
sophisticated and useful features that might not have been expected. Still, when computing became mainstream, there was a realization that people wanted friendly GUI interfaces. Soon there came a flood of email clients, some of them even cross-platform and compatible among Linux, Windows, and Mac OS X, and even traditional UNIX.

**Evolution**

Evolution is the standard email client that comes with Ubuntu, although to call it simply an email client is to sincerely underrate its usefulness as an application. Not only does it handle email, but it can also look after contacts and calendars and help you manage your tasks (see Figure 5.4).

![Evolution Email Client](image)

**FIGURE 5.4** With Evolution you can handle all your email and contacts, as well as make appointments and track tasks.

You need to have the following information to successfully configure Evolution (or any email client):

- Your email address
- Your incoming email server name and type (that is, pop.email.com, POP, and IMAP)
- Your username and password for the incoming mail server
- Your outgoing mail server name (that is, smtp.email.com)

As many people are moving to web-based mail options like Google's Gmail or Yahoo! Mail, email programs have started to decline in popularity. One thing that sets Evolution
apart is that you can still use it for the other features and disable the email portion of the program by selecting “none” as your mail transfer agent instead of POP, IMAP, and so on. In addition, Evolution can interact with an existing web calendar program if it uses one of the common formats, such as CalDAV. This allows you to use your calendar remotely as you are used to, but also permits the Ubuntu desktop to have access to your events and embed them into your desktop panel (which it does by default using Evolution).

**Mozilla Thunderbird**

Mozilla Thunderbird (see Figure 5.5) is the sister program to Firefox. Whereas Firefox is designed to browse the Web, Thunderbird’s specialty is communication. It can handle email, network news (see later in this chapter), and RSS feeds.

![Mozilla Thunderbird](image)

**FIGURE 5.5** The natural companion to Firefox, Mozilla’s lightweight email client, Thunderbird, can be found in use all over the world.

Thunderbird is not installed by default with Ubuntu, but you can install it from the Ubuntu repositories. The package is called thunderbird. As with Firefox, there are many plug-ins and extensions to enhance your email. You can also use Thunderbird for Usenet news reading.
Other Mail Clients

The mail clients that we've covered are only a few of those available. Claws is very popular because it offers spell check while typing and is well suited for use in large network environments in which network overhead and RAM usage are important considerations. Mutt is an older text-based email program that is still beloved by sysadmins for its configurability and feature set, including the easy use of GPG keys for signing email. Alpine is another text-based program based on the classic Pine, with a few upgrades. Kmail is commonly used by lovers of the KDE desktop that is commonly run as a part of many Linux-based operating systems. All of these and more are available for installation from the Ubuntu software repositories.

RSS Readers

RSS is one of the protocols of Web 2.0, the current generation of Internet content. RSS has really taken off, thanks to adoption by a large number of websites and portals.

The key advantage of RSS is that you can quickly read news from your choice of websites at a time that suits you and from one location, meaning you don’t have to go to each site to view their content. Some services offer just the articles’ headlines, whereas others offer full articles for you to view. RSS feeds can be accessed in various ways, even through your web browser!

Firefox

Firefox implements RSS feeds as what it calls Live Bookmarks (shown in Figure 5.6), which are essentially bookmarks with sub-bookmarks, each linking to a new page from your chosen website. Some people like to have several news sites grouped together in a folder called News in the Firefox toolbar, because this allows them to quickly browse through a collection of sites and pick out articles of interest.

FIGURE 5.6 Live Bookmarks for Firefox, making all your news fixes just a mouse click away.
Liferea

Of course, not everyone wants to read RSS feeds with the browser. The main problem with reading RSS feeds with Firefox is that you get to see only the headline, rather than any actual text. This is where a dedicated RSS reader comes in handy, and Liferea (see Figure 5.7) is one of the best.

It is not installed by default but Liferea is available from the repositories under the name liferea. After it is installed, you can find it in the menu at Applications, Internet, Liferea.

By default, Liferea offers a number of RSS feeds, including Planet Debian, Groklaw, and Slashdot. Adding a new feed is straightforward. You select New Subscription under the Feeds menu and paste the URL of the RSS feed into the box. Liferea then retrieves all the current items available through that field, and displays the feed name on the left side for you to select and start reading.

Instant Messaging and Video Conferencing with Empathy

Instant Messaging is one of the biggest ways for people to interact over the Web. AOL was the primary force behind this, especially in America, but other networks and systems soon came onto the market, providing users with a wealth of choice.

No longer just a consumer tool, instant messaging is now a part of the corporate world, with many companies deploying internal instant messaging software for collaboration.

Empathy is the default messaging program in Ubuntu; it can be found in the menu at Applications, Internet, Empathy and can be seen in Figure 5.8. It supports text, voice, and
video chat as well as file transfers using common protocols like Google Talk, AIM, and more. All you have to do is know your account information with a specific service and enter it in to Empathy—and the rest is easy.

![Image of Empathy](image.png)

**FIGURE 5.8** Empathy is easy to set up and use for great collaboration.

You can learn more about Empathy at https://help.ubuntu.com/community/Empathy.

### Internet Relay Chat

As documented in RFC 2812 and RFC 2813, the IRC protocol is used for text conferencing. Like mail and news, IRC uses a client/server model. Although it is rare for an individual to set up and run an IRC server, it can be done. Most people use public IRC servers and access them with IRC clients. IRC is also the favorite and most common form of quick communication among developers in the Ubuntu community, so if that interests you, then you will certainly want to learn to use this tool.

Ubuntu provides a number of graphical IRC clients in the repositories, including XChat, Pidgin, and Quassel. You can even use Empathy, although other products are better suited for this specific task. Ubuntu also makes the console clients epic and irssi available in the repositories for those who eschew X and a graphical interface. Don’t laugh, there are actually many who do this, and not just server admins, especially because they can be run on a remote server and accessed over SSH using Byobu or Screen allowing them to be left running 24/7 on that remote server. For more about Byobu and Screen, see Chapter 35, “Command Line Masterclass.” If you don’t already have a favorite IRC client, you should try them all.
XChat is a very popular IRC client, and the most common recommendation for IRC newcomers using Ubuntu, so we will use it as an example. After you install the program, the documentation for XChat is available in `/usr/share/docs/xchat`. It is a good idea to read them before you begin because they include an introduction and cover some of the basics of IRC.

The XChat application enables you to assign yourself up to three nicknames. You can also specify your real name and your username. Because many people choose not to use their real names in IRC chat, you are free to enter any names you desire in any of the spaces provided. You can select multiple nicknames; you might be banned from an IRC channel under one name, and you could then rejoin using another. If this seems slightly juvenile to you, you are beginning to get an idea of the type of behavior on many IRC channels (but not the ones where serious developer and Ubuntu community interactions take place).

When you open the main XChat screen, a list of IRC servers appears, as shown in Figure 5.9. After you choose a server by double-clicking it, you can view a list of channels available on that server by choosing Window, Channel List. The XChat Channel List window appears. In that window, you can choose to join channels featuring topics that interest you. To join a channel, you double-click it. Ubuntu uses irc.freenode.net for the server and the primary support channel is #ubuntu.

![XChat: Network List](image)

**FIGURE 5.9** The main XChat screen presents a list of available public servers from which to select.
THE WILD SIDE OF IRC

Do not be surprised at the number of lewd topics and the use of crude language on public IRC servers. For a humorous look at the topic of IRC cursing, see www.irc.org/fun_docs/nocuss.html. This site also offers some tips for maintaining IRC etiquette, which is essential if you do not want to be the object of any of that profanity! Here are some of the most important IRC etiquette rules:

- Do not use colored text, all-capitalized text, blinking text, or “bells” (beeps caused by sending ^G to a terminal).
- Show respect for others.
- Ignore people who act inappropriately.

After you select a channel, you can join in the conversation, which appears as onscreen text. The messages scroll down the screen as new messages appear. For an example, see Figure 5.10. You can continue learning about IRC at https://help.ubuntu.com/community/InternetRelayChat.

FIGURE 5.10 Join in an online chatroom about your favorite distro, with XChat.

TIP

You can establish your own IRC server even though Ubuntu does not provide one. Setting up a server is not a task for anyone who is not well versed in Linux or IRC. A popular server is IRCd, which you can obtain from ftp://ftp.irc.org/irc/server/. Before you download IRCd, you should look at the README file to determine what files you need to download, and read the information at http://www.irchelp.org/irchelp/ircd/.
Usenet Newsgroups

The concept of newsgroups revolutionized the way information was exchanged between people across a network. The Usenet network news system created a method for people to electronically communicate with large groups of people with similar interests. As you will see, many of the concepts of Usenet news are embodied in other forms of collaborative communication.

Usenet newsgroups act as a form of public bulletin board system. Any user can subscribe to individual newsgroups and send (or post) messages (called articles) to the newsgroup so that all the other subscribers of the newsgroup can read them. Some newsgroups include an administrator, who must approve each message before it is posted. These are called moderated newsgroups. Other newsgroups are open, allowing any subscribed member to post a message. When an article is posted to the newsgroup, it is transferred to all the other hosts in the news network.

Usenet newsgroups are divided into a hierarchy to make it easier to find individual newsgroups. The hierarchy levels are based on topics, such as computers, science, recreation, and social issues. Each newsgroup is named as a subset of the higher-level topic. For example, the newsgroup comp relates to all computer topics. The newsgroup comp.laptops relates to laptop computer issues. Often the hierarchy goes several layers deep. For example, the newsgroup comp.databases.oracle.server relates to Oracle server database issues.

NOTE

The format of newsgroup articles follows the strict guidelines defined in the Internet standards document Request for Comments (RFC) 1036. Each article must contain two distinct parts: header lines and a message body.

The header lines identify information about when and by whom the article was posted. The body of the message should contain only standard ASCII text characters. No binary characters or files should be posted within news articles. To get around this restriction, binary files are converted to text data, through use of either the standard UNIX uencode program or the newer Multipurpose Internet Mail Extensions (MIME) protocol. The resulting text file is then posted to the newsgroup. Newsgroup readers can then decode the posted text file back into its original binary form.

A collection of articles posted in response to a common topic is called a thread. A thread can contain many articles as users post messages in response to other posted messages. Some newsreader programs allow users to track articles based on the threads to which they belong. This helps simplify the organization of articles in the newsgroup.
TIP

The free news server, news.gmane.org makes the Red Hat and Ubuntu mail lists available via newsgroups. The beta list is available as gmane.linux.redhat.rhl.beta. It is a handy way to read threaded discussions and some prefer it to using the Ubuntu mail list archives.

The protocol used to transfer newsgroup articles from one host to another is Network News Transfer Protocol (NNTP), defined in RFC 975. (You can search RFCs at ftp://metalab.unc.edu/pub/docs/rfc/; look at the file rfc-index.txt.) NNTP was designed as a simple client/server protocol that enables two hosts to exchange newsgroup articles in an efficient manner.

Whether or not your Ubuntu machine is set up as a news server, you can use a newsreader program to read newsgroup articles. The newsreader programs require just a connection to a news server. It does not matter whether the news server is on the same machine or is a remote news server on the other side of the world.

Several programs are available to connect to news servers to read and post articles in newsgroups. If you are interested in Usenet, you might want to check out a program from the Ubuntu repositories called Pan. Pan is a graphical newsreader client that has the capability to download and display all the newsgroups available on a server and display posted news articles. However, Usenet is an old system that predates the creation of the World Wide Web. It was the place to be in the early days and the source of many great memories, but today is little better than a ghost town with wind-blown tumbleweeds, spam, and illegal exchanges of pirated content. Most Internet service providers used to run free Usenet servers, and connecting was easy and common, but most of the free ones are gone now and traffic has dwindled. Feel free to experiment or try to relive the glory days, but Usenet is, alas, well past its prime.

Ubuntu One Cloud Storage

Anyone who has installed Ubuntu has access to a free online cloud storage application called Ubuntu One. The service is built in to the Ubuntu desktop, and the best place to begin is from the menu at System, Preferences, Ubuntu One. By signing up you will receive 2GB of space to use to store anything you would like and make it available to multiple computers with access from Ubuntu desktops (with plans to expand to other Linux distributions and even other operating systems in the future) as well as via a web interface. If that isn’t enough space, larger accounts are available for a fee, which in turn helps support future Ubuntu development. An Ubuntu One account is also needed to purchase music from the Ubuntu One Music Store, covered in Chapter 7, “Multimedia Applications.”

CHAPTER 6
Productivity Applications

Many businesses have already found a way to benefit from open source software, such as office productivity suites like OpenOffice.org and its commercial counterpart, StarOffice, recently renamed Oracle Open Office. These have the cost benefits of not having to pay license fees or support costs. However, more applications beyond these are available in Ubuntu. In this chapter we will explore some of them.

NOTE
It’s important to understand that even though OpenOffice.org does very well most of the time, especially with less-complex documents, it is not 100 percent compatible with Microsoft Office. Why is this? Microsoft is notoriously secretive about its proprietary file formats, and the only way that OpenOffice.org could ensure compatibility would be to reverse-engineer each file format, an exercise akin to taking apart a telephone to see how it works. This reverse-engineering is difficult to do in a legal way and is rarely perfect. However, OpenOffice.org manages to maintain a very high standard of importing and exporting, so you should not experience too many problems except with documents of great complexity. As an example, this book was primarily written using OpenOffice.org, whereas the post-production at the publisher uses Microsoft tools.

A productivity suite is defined as two or more applications bundled together and used for creating documents, presentations, spreadsheets, and databases. Other applications that
may be included in the bundle are email clients, calculators/formula editors, illustration or drawing software, and more. Commonly, they are all tied together by a default look and feel, which makes sticking to one particular suite much easier. Because Ubuntu uses OpenOffice.org as its standard office suite, we will introduce you to Writer and Calc, the two most popular OpenOffice.org components. We will also take a brief look at some of the other Linux-based office suites.

**WORKING WITH OPENOFFICE.ORG**

For the majority of users of productivity suites, OpenOffice.org should fulfill most, if not all, of your requirements. However, the first hurdle is not whether it can do what you require of it, but rather whether it can successfully import and export to proprietary Microsoft formats at a standard that is acceptable to your needs. In the main, OpenOffice.org should import and export with minimal hassle, perhaps getting a bit stuck with some of the more esoteric Microsoft Office formatting. Given that most users do not go much beyond tabs, columns, and tables, this level of compatibility should suffice.

However, you are strongly advised to round up a selection of documents and spreadsheets that seem the most likely to be difficult for the import/export filter and test them thoroughly (of course, keeping a backup of the originals!). There is nothing worse for a system administrator who has deployed a new productivity suite than to suddenly get users complaining that they cannot read their files. This would quickly destroy any benefits gained from the other useful functions within OpenOffice.org, and could even mark the return of proprietary formats and expensive office suites.

On the positive side, OpenOffice.org supports a huge array of file formats and is capable of exporting to nearly 70 types of documents. Such a variety of file formats means that you should be able to successfully use OpenOffice.org in nearly any environment, including formats no longer used by currently produced and maintained software, so it may be able to open some old files and documents you had once given up for lost.

**Introducing OpenOffice.org**

OpenOffice.org contains a number of productivity applications for use in creating text documents, preparing spreadsheets, organizing presentations, managing projects, and so on. The following components of the OpenOffice.org package are included with Ubuntu:

- **Writer**—This word processing program enables you to compose, format, and organize text documents. If you are accustomed to using Microsoft Word, the functionality of OpenOffice.org Writer will be familiar to you. You will learn how to get up and running with Writer later on in this chapter.

- **Calc**—This spreadsheet program enables you to manipulate numbers in a spreadsheet format. Support for all but the most esoteric Microsoft Excel functions means that trading spreadsheets with Excel users should be successful. Calc offers some limited compatibility with Excel macros, but those macros generally have to be
Introducing OpenOffice.org

rewritten. We walk through setting up a basic spreadsheet with some formulas and show you how to build a basic Data Pilot later on in this chapter.

- **Impress**—This presentation program is similar to Microsoft PowerPoint and enables you to create slide show presentations that include graphs, diagrams, and other graphics. Impress also works well with PowerPoint files.

**NOTE**

The following five applications are not included by default with Ubuntu, but are quite useful. All but Dia are a part of the OpenOffice.org project and add features to the suite that are not used as often as those Ubuntu installs by default. You will need to install them from the Ubuntu repositories if you desire or require their functionality.

- **Math**—This math formula editor enables you to write mathematical formulas with a number of math fonts and symbols for inclusion in a word processing document. Such symbols are highly specialized and not easily included in the basic functionality of a word processor. This is of interest primarily to math and science writers, but Math can be useful to anyone who needs to include a complex formula in text.

- **Base**—This is a fully functional database application.

- **Draw**—This graphics application allows you to create images for inclusion in the documents produced with OpenOffice.org. It saves files only in OpenOffice.org format, but it can import most common image formats.

- **Dia**—This technical drawing editor from the GNOME Office suite enables you to create measured drawings, such as those used by architects and engineers. Its functionality is similar to that of Microsoft Visio. When installed, it is found in the menu under Applications, Graphics, Dia Diagram Editor.

- **Planner**—You can use this project management application for project planning, scheduling, and tracking; this application is similar to, but not compatible with, Microsoft Project. It is found in the Office menu as the Project Management item.

**A BRIEF HISTORY OF OPENOFFICE.ORG**

The OpenOffice.org office suite is based on a commercial suite called StarOffice. Originally developed by a German company, StarOffice was purchased by Sun Microsystems in the United States. One of the biggest complaints about the old StarOffice was that all the component applications were integrated under a StarOffice “desktop” that looked very much like a Microsoft Windows desktop, including a Start button and menus. This meant that to edit a simple document, unneeded applications had to be loaded, making the office suite slow to load, slow to run, and quite demanding on system resources.
After the purchase of StarOffice, Sun Microsystems released a large part of the StarOffice code under the GNU Public License, and development began on what has become OpenOffice.org, which is freely available under the GPL. Sun also continued development on StarOffice. The significant differences between the free and commercial versions of the software are that StarOffice provides more fonts and even more import/export file filters than OpenOffice.org (these filters cannot be provided in the GPL version because of licensing restrictions), and StarOffice provides its own relational database, Software AGs Adabas D database.

Recently, Sun was bought by Oracle. Although no announcements have been made, there is some question as to what will happen with OpenOffice.org under the new owners. To make things more interesting, IBM has imported the GPL-licensed OpenOffice codebase and released its own free-as-in-cost office suite based on it called Lotus Symphony, which also has some proprietary additions.

Configuring OpenOffice.org

The installation of OpenOffice.org is done on a systemwide basis, meaning that all users have access to it. However, users may configure OpenOffice.org for their individual needs. This initial configuration happens the first time each user loads any one of the OpenOffice.org components, and might mean the application takes a little longer to load that first time.

TIP

OpenOffice.org is constantly improving its productivity applications. You can check the OpenOffice.org website (http://www.openoffice.org/) for the latest version. The website provides a link to download the source or a precompiled version of the most current working installation files. A more current version might offer file format support that you need. Should you need a Windows-compatible version, you will also find it at the website.

Figure 6.1 shows the Office menu, which is found under Applications. You can see the entries for Presentation (Impress), Spreadsheet (Calc), and Word Processor (Writer).

FIGURE 6.1 The OpenOffice.org suite provided by Ubuntu is simple to configure and use.
As is the case with many Linux applications, you may be somewhat overwhelmed by the sheer number of configuration options available to you in OpenOffice.org. Mercifully, a lot of thought has gone into organizing these options, which are available if you click the Tools menu and select Options. It does not matter which program you use to get to this dialog box; it appears the same if summoned from Writer, Impress, or Calc. It acts as a central configuration management tool for all OpenOffice.org applications. You can use it to set global options for all OpenOffice.org applications, or specific options for each individual component. For instance, in the dialog shown in Figure 6.2, you can change the user details and information, and this is reflected across all OpenOffice.org applications.

OpenOffice.org is a constant work in progress, but the current release is on par with the Sun version of StarOffice 8. You can browse to the OpenOffice.org website to get documentation and answers to frequently asked questions and to offer feedback.

**Working with OpenOffice.org Writer**

Of all the applications that make up OpenOffice.org, the one that you are most likely to use regularly is Writer, the OpenOffice.org word processor. With a visual style very similar to Microsoft’s Word, Writer has a number of strengths over its commercial and vastly more expensive rival. In this section you will learn how to get started with Writer and make use of some of its powerful formatting and layout tools.

**NOTE**

You may be interested to know that Writer was the primary word processor chosen to write and edit this book.
Getting Started with Writer

You can access Writer from the menu at Applications, Office, selecting OpenOffice.org Word Processor. After a few seconds Writer opens up with a blank document and a blinking cursor awaiting your command. It can be tempting to just dive in and start typing your document, but it can be worthwhile to do some initial configuration before you start work.

First, make sure that the options are set to your requirements. Click the Tools menu and select Options to bring up the Options dialog box, as shown in Figure 6.2. The initial screen allows you to personalize OpenOffice.org with your name, address, and contact details, but there are options to configure features that you might also want to alter. Check that your default paths are correct by clicking the Paths option. You may prefer to alter the My Documents path, as shown in Figure 6.3, to something a little more specific than just the Documents directory.

![Click the Edit button to choose your default documents directory.](image)

FIGURE 6.3 Click the Edit button to choose your default documents directory.

You can set OpenOffice.org to save in Microsoft Word format by default, should you so require. This can be done under the Load/Save General options shown in Figure 6.4, and it is a good idea if you value your work to change the Autorecovery settings so that it saves every couple of minutes.

Also shown in Figure 6.4 are a number of options that are specific to Writer. A little bit of time working through these options can give you a highly personalized and extremely productive environment.

Working with Styles and Formatting

One of the significant benefits of using Writer is the ability to easily apply formatting and styles to extremely complex documents. Depending on the types of documents you work
with, you might want to consider creating your own styles beyond the 20 included by default. You can access styles through either the Style drop-down box in the toolbar or the Styles and Formatting window shown in Figure 6.5. If you cannot see the window, press the F11 key to display it.

![FIGURE 6.4 Make sure that you are working with most appropriate file formats.](image)

The easiest way to work with the Styles and Formatting tool is to highlight the text you want to style and double-click the required style in the window. There are quite a few to choose from, but you might find them restrictive if you have more specialized needs. To

![FIGURE 6.5 Writer’s quick and easy-to-use Styles and Formatting tool.](image)
start defining your own styles, click the button shown in Figure 6.6 to bring up options to
add, modify, and load styles for pages, paragraphs, lists, characters, and frames.

![Styles and Formatting](image)

**FIGURE 6.6** You can control styling from a submenu in Styles and Formatting.

### Working with OpenOffice.org Calc

The spreadsheet component of OpenOffice.org is named Calc, and is a very capable Excel alternative.

Calc is used for storing numerical information that you need to analyze in some way. For instance, you could use it to help you budget month by month. It can take care of the calculations for you, as long as you tell Calc what you want it to do. Anyone with experience in Excel will feel right at home with Calc.

In this section, we will show you how to get started with Calc, including entering formulas and formatting. We will also take a look at some of the more advanced features of Calc, including the Data Pilot feature, which allows you to easily summarize information.

### Getting Started with Calc

You can either click the shortcut icon that is located on the top GNOME panel, or select Spreadsheet from the Office menu under the Applications main menu. Whichever route you take, the result is the same and Calc starts to load.

By default, Calc loads with a blank spreadsheet ready for you to enter information into it, as in Figure 6.7.

Calc's layout makes it easy to organize information into rows and columns. As you can see in the example, we have salespeople listed in the left column, customers in the second column, Invoice Date in the third column, and finally Revenue in the fourth column. At the moment, there are no formulas entered to help you interpret the data. Clicking the E30 cell selects it and enables you to enter a formula in the top formula bar. If you begin with the equal sign, Calc knows that you are entering a formula and works accordingly.

In this example, we want to know the total revenue brought in up to now, so the formula to enter is =sum(E4:E29), followed by Return. Calc automatically enters the result into cell E43 for you to see. Now you want to see what the average order value was. To do this, you have to obtain the number of orders made. For this you can use the counta function to count the number of entries in a given list. This is usually used when you need to find out how many entries are in a text list. So, in cell B30, enter =counta(B4:B29) and press Enter. Calc now counts the number of entries in the range and returns the total in B43. Then you need to divide the total revenue by the number of orders to find the average order value. So, in cell E31, enter the formula =E30/B30 to get the average order value.
FIGURE 6.7  Use Calc to store numerical and statistical information.

**TIP**
Calc offers some nifty little features that you can use quickly. The handiest one in our opinion is the capability to select multiple cells and see straight away the total and average of the range. You will find these figures in the bottom-right status bar. This has saved us numerous times when we have needed to get this information quickly!

**Formatting Spreadsheets**
Getting back to our example, it looks a little basic at the moment because no formatting is involved. For instance, what’s the billing currency? You can also see that some of the cells have text that does not fit, which is highlighted by a small right arrow in the cell. We should also add some labels and titles to our spreadsheet to make it a bit more visually appealing.

To start, all the revenue figures can be changed into currency figures. To do this, select all the cells containing revenue information and click the small coin icon shown in Figure 6.8. This immediately formats the cells so that they display the dollar sign and also puts in a thousands separator to make the numbers easier to read.

FIGURE 6.8  Make numbers more meaningful with the currency and percentage icons.
Now you need to space all the cells so that you can read all the information. A quick and easy way to do this is to click the area immediately to the left of column A and immediately above row 1 to select the entire spreadsheet. Now all you have to do is double-click the dividing lines, and each column resizes according to its longest entry.

Next you can add a little color to the worksheet by using the paint can icon in the toolbar. Select the range B2 to E2 with the mouse cursor and click the background color icon to bring up the color window shown in Figure 6.9. Select the color you want to use and Calc fills the cells with that color. You can also change the font color by using the icon immediately to the right in the same way.

![Figure 6.9 - Add a touch of color to an otherwise dull spreadsheet with the fill background icon.](image)

Finally, you need a couple more finishing touches. The first is to enlarge the font for the column headers. Select the range B2 to E2 again and click the font size in the toolbar to change it to something a little larger. You might also want to use the bold and italic options to further emphasize the headers and the totals.

If you have followed the steps as described, you should end up with a spreadsheet similar to the one in Figure 6.10.

**Summarizing Data with Calc**

Calc includes a powerful tool that lets you summarize large groups of data to help you when you need to carry out any analysis. This tool is called a data pilot, and you can use it to quickly summarize data that might normally take a long time if you did the calculations manually. Using the sample spreadsheet from earlier, we will take you through how to build a simple data pilot and show you how to analyze and manipulate long lists of data.

The previous section featured a spreadsheet that showed salespeople, customers, date of invoice, and revenue. At the foot of the spreadsheet were a couple of formulas that enabled you to quickly see the total revenue earned and the average order value.
Now you want to find out how much salespeople have earned individually. You could add this up manually with a calculator, but that would defeat the point of using Calc. So, you need to create a data pilot to summarize the information.

First, you need to select all the cells from B2 to E42 because they contain the data you want to analyze. After these are selected, click the Data menu and select Data Pilot, Start to open the Data Pilot Wizard. The first screen is shown in Figure 6.11 and is defaulted to Current Selection. Make sure that you choose this one to use the data in the selected range, and click OK to continue.

The next screen enables you to lay out your data pilot as you want it. In this example you want to have the Sales Person in the left column marked Row Fields, so click and drag the Sales Person option from the list on the right and drop it onto the Row Fields area. You’re
also interested in the average unit rate for each salesperson, so drag Unit Rate into the Data Fields section and double-click it. In the window that comes up, select Average from the list and click the OK button. Finally, drag Revenue to the Data Field area so you can see how much revenue each salesperson brought in. You should end up with something like Figure 6.12; you are almost ready to display your data pilot.

The final piece in the puzzle is to tell Calc where you want to place the finished data pilot. To do this, click the More button to drop down some extra options and select the box Send Results To to choose a new sheet. When you click OK now, Calc builds the data pilot and displays it on a new sheet in your workbook. The new data pilot is shown in Figure 6.13.

**Office Suites for Ubuntu**

As we have mentioned earlier, OpenOffice.org is the default application suite for Ubuntu. However, as is common in the open source world, there are plenty of alternatives should you find that OpenOffice.org does not meet your specific requirements. These include the popular Gnome Office and also KOffice, the default KDE productivity suite. You are more likely to hear more about OpenOffice.org, especially as more and more people realize that it is generally compatible with Microsoft Office file formats. Interestingly, the state of Massachusetts not long ago elected to standardize on two file formats for use in government: the Adobe Acrobat PDF format and the OASIS OpenDocument format, both of which are supported natively in OpenOffice.org.
FIGURE 6.13 Summarize large volumes of numerical data with ease, using Calc’s Data Pilot function.

NOTE

The decision by the state of Massachusetts to standardize on PDF and OpenDocument has huge ramifications for the open source world. It is the first time that OpenDocument, an open standard, has been specified in this way. It means that anyone who wants to do business with the state government must use OpenDocument-based file formats, and not the proprietary formats in use by Microsoft. Unfortunately for Microsoft, it does not have support for OpenDocument in any of its applications, making them useless to anyone wanting to work with the state government. This is despite Microsoft being a founding member of OASIS, who developed and ratified the OpenDocument standard.

Working with Gnome Office

The other office suite available for GNOME is Gnome Office, which is a collection of individual applications. Unlike OpenOffice.org, Gnome Office does not have a coherent suite of applications, meaning that you have to get used to using a word processor that offers no integration with a spreadsheet and cannot work directly with a presentation package. However, if you need only one or two components, it is worthwhile investigating Gnome Office.
THE GTK WIDGET SET

Open Source developers are always trying to make it easier for people to build applications and help in development. To this end, there are a number of widgets or toolkits that other developers can use to rapidly create and deploy GUI applications. These widgets control things such as drop-down lists, Save As dialogs, window buttons, and general look and feel. Unfortunately, whereas Windows and Apple developers have to worry about only one set of widgets each, Linux has a plethora of different widgets, including GTK+, QT, and Motif. What is worse is that these widgets are incompatible with one another, making it difficult to easily move a finished application from one widget set to another.

GTK is an acronym for GIMP Tool Kit. GIMP, the GNU Image Manipulation Program, is a graphics application very similar to Adobe Photoshop. By using the GTK-based jargon, we save ourselves several hundred words of typing and help move along our discussion of GNOME Office. You might also see similar references to QT and Motif, as well as other widget sets, in these chapters.

Here are some of the primary components of the Gnome Office suite that are available in Ubuntu:

- **AbiWord**—This word processing program enables you to compose, format, and organize text documents and has some compatibility with the Microsoft Word file format. It uses plug-ins (programs that add functionality such as language translation) to enhance its functionality.

- **Gnumeric**—This spreadsheet program enables you to manipulate numbers in a spreadsheet format. Support for all but the most esoteric Microsoft Excel functions means that users should have little trouble trading spreadsheets with Excel users.

- **GIMP**—This graphics application allows you to create images for general use. It can import and export all common graphic file formats. GIMP is similar to Adobe’s Photoshop application and is described in Chapter 7, “Multimedia Applications.”

- **Evolution**—Evolution is a mail client with an interface similar to Microsoft Outlook, providing email, scheduling, and calendaring. It is described in Chapter 5, “On the Internet.”

The loose association of applications known as Gnome Office includes several additional applications that duplicate the functionality of applications already provided by Ubuntu. Those extra GNOME applications are not included in a default installation of Ubuntu to eliminate redundancy. They are all available from the Gnome Office website, at www.gnome.org/gnome-office/. Evolution is available with Ubuntu by default. You have to install the remaining components using the Ubuntu repositories.

Ubuntu provides the AbiWord editor, shown in Figure 6.14, as part of its Extras. AbiWord can import XML, Microsoft Word, RTF, UTF8, plain text, WordPerfect, KWord, and a few other formats. AbiWord is notable for its use of plug-ins, or integrated helper applications,
that extend its capabilities. These plug-ins add language translation, HTML editing, a thesaurus, a Linux command shell, and an online dictionary, among other functions and features. If you need a simple yet powerful word processing application, you should examine AbiWord.

AbiWord is not installed by default in Ubuntu, so you’ll need to install it either using `apt-get` or `synaptic`. The package is simply called `abiword`, although you might want to install the meta-package `gnome-office`, which will include the other Gnome Office applications.

After you’ve installed Abiword, it becomes available in the Applications menu, under the Office submenu. Simply click the icon to launch the application.

If you are familiar with Microsoft Works, the AbiWord interface will be familiar to you because its designers based the interface on Works.

You can use the Gnumeric spreadsheet application to perform financial calculations and to graph data, as shown in Figure 6.15. It can import comma- or tab-separated files, text, or files in the Gnumeric XML format, saving files only as XML or text. You need to install Gnumeric using either `apt-get` or `synaptic` in the same way as Abiword. If you have already installed the `gnome-office` package, Gnumeric will be available under Applications, Office as Gnumeric Spreadsheet.
After you press Enter, the main Gnumeric window appears. You enter data in the spreadsheet by clicking a cell and then typing in the text box. To create a graph, you click and drag over the spreadsheet cells to highlight the desired data, and then you click the Graph Wizard icon in Gnumeric’s toolbar. Gnumeric’s graphing component launches, and you are guided through a series of dialogs to create a graph. When you are finished, you can click and drag a blank area of your spreadsheet, and the graph appears.

The Project Planner application is useful for tracking the progress of projects, much like its Windows counterpart, Microsoft Project. When the main window is displayed, you can start a new project or import an existing project. The application provides three views: Resources, Gantt Charts, and Tasks.

**Working with KOffice**

The KDE office suite KOffice was developed to provide tight integration with the KDE desktop. Integration enables objects in one application to be inserted in other applications via drag-and-drop, and all the applications can communicate with each other, so a change in an object is instantly communicated to other applications. The application integration provided by KDE is a significant enhancement to productivity. (Some GNOME desktop applications share a similar communication facility with each other.) If you use the KDE
desktop instead of the default GNOME desktop, you can enjoy the benefits of this integration, along with the Konqueror web and file browser.

The word processor for KOffice is KWord. KWord is a frames-based word processor, meaning that document pages can be formatted in framesets that hold text, graphics, and objects in enclosed areas. Framesets can be used to format text on a page that includes text and images within columns that the text needs to flow around, making KWord an excellent choice for creating documents other than standard business letters, such as newsletters and brochures.

KWord and other components of KOffice are still under development and lack all the polished features of OpenOffice.org and AbiWord. However, it does have the capability to work with the OpenDocument format found in OpenOffice.org, as well as limited compatibility with Microsoft file formats.

You can access the KOffice components from the Office menu.

KWord asks you to select a document for your session. The KWord client, shown in Figure 6.16, offers sophisticated editing capabilities, including desktop publishing.

![KWord Client](image)

FIGURE 6.16 The KOffice KWord word processing component is a sophisticated frames-based WYSIWYG editor that is suitable for light desktop publishing, supporting several formats, including WordPerfect.

The KOffice KSpread client is a functional spreadsheet program that offers graphing capabilities. Like KWord, KSpread can be accessed from the Office menu.
KDE includes other productivity clients in its collection of KOffice and related applications. These clients include an address book, time tracker, calculator, notepad, and scheduler. One popular client is Kontact, which provides daily, weekly, work week, and monthly views of tasks, to-do lists, and scheduled appointments with background alarms. A journal, or diary, function is also supported within it, and you can synchronize information with your Palm Pilot. You can launch this client from the Office menu.

A typical Kontact window is shown in Figure 6.17.

![Kontact Window](image)

**FIGURE 6.17** KDE’s Kontact client supports editing of tasks and schedules that you can sync with your PDA. Shown here is the address book.

### Productivity Applications Written for Microsoft Windows

Microsoft Windows is fundamentally different from Linux, yet you can install and run some Microsoft Windows applications in Linux by using an application named Wine. Wine enables you to use Microsoft Windows and DOS programs on Unix-based systems. Wine includes a program loader that you can use to execute a Windows binary, along with a .dll library that implements Windows command calls, translating them to the equivalent Unix and X11 command calls. Because of frequent updates to the Wine code base, Wine is not included with Ubuntu. Download a current version of Wine from [www.winehq.org/](http://www.winehq.org/). To see whether your favorite application is supported by Wine, you can look at the Wine application database at [http://appdb.winehq.org/appbrowse.php](http://appdb.winehq.org/appbrowse.php).

Other solutions, primarily CodeWeavers’ CrossOver Office, enable use of Microsoft productivity applications. If you are after a painless way of running not only Microsoft
Office, but also Apple iTunes and other software, you should investigate CodeWeavers. CrossOver Office is one of the simplest programs you can use to get Windows-based programs to work. Check out www.codeweavers.com to download a trial version of the latest software. It requires registration, but do not worry—the guys at CodeWeavers are great and will not misuse your details. The big plus is that you get a whole month to play around with the trial before you decide whether to buy it. Of course, you might get to the end of the 30 days and realize that Linux does what you want it to do and you don’t want to go back to Windows. Do not be afraid; take the plunge!

### RELEVANT UBUNTU COMMANDS

The following commands give you access to productivity applications, tools, and processes in Ubuntu if you want or need to start them from the command line:

- `oowriter`—OpenOffice.org’s Writer
- `oocalc`—OpenOffice.org’s Calc
- `ooimpress`—OpenOffice.org’s Impress
- `kossh`—KDE’s KOffice office suite shell
- `kspread`—KDE’s KSpread spreadsheet
- `gimp`—The GIMP (GNU Image Manipulation Package)
- `gnumeric`—A spreadsheet editor for GNOME
- `planner`—A project management client for GNOME
- `abiword`—A graphical word processor for GNOME

CHAPTER 7
Multimedia Applications

The twenty-first century has become the century of the digital lifestyle, with millions of computer users around the world embracing new technologies, such as digital cameras, MP3 players, and other assorted multimedia gadgets. Whereas ten years ago you might have had a small collection of WAV files scattered about your Windows installation, today you are more likely to have hundreds, if not thousands, of MP3 files scattered across various computers. Along with video clips, animations, and other graphics, the demand for organizing and maintaining these vast libraries is driving development of applications. Popular proprietary applications such as iTunes and Google's Picasa are coveted by Linux users, but open source applications are appearing that provide real alternatives, and for some people these the final reasons they need to move to Linux full time.

This chapter provides an overview of some of the basic multimedia tools included with Ubuntu. You will see how to create your own CDs, watch TV, rip audio CDs into the open source Ogg audio format for playback, as well as manage your media library. You will also learn about how Ubuntu handles graphics and pictures and more.

Sound and Music

Linux had a reputation of lacking good support for sound and multimedia applications in general. However, great strides have been made in recent years to correct this, and support is now a lot better than it used to be. (It might make you smile to know that Microsoft no longer supports the Microsoft Sound Card, but Linux users still enjoy support for it, no doubt just to annoy the folks in
Redmond.) UNIX, however, has always had good multimedia support as David Taylor, UNIX author and guru, points out:

The original graphics work for computers was done by Evans & Sutherland on UNIX systems. The innovations at MIT’s Media Lab were done on UNIX workstations. In 1985, we at HP Labs were creating sophisticated multimedia immersive work environments on UNIX workstations, so maybe UNIX is more multimedia than suggested. Limitations in Linux support doesn’t mean UNIX had the same limitations. I think it was more a matter of logistics, with hundreds of sound cards and thousands of different possible PC configurations.

That last sentence sums it up quite well. UNIX had a limited range of hardware to support; Linux has hundreds of sound cards. Sound card device driver support has been long lacking from manufacturers, and there is still no single standard for the sound subsystem in Linux.

In this section, you learn about sound cards, sound file formats, and the sound applications provided with Ubuntu.

**Sound Cards**

Ubuntu supports a wide variety of sound hardware and software. Two models of sound card drivers compete for prominence in today’s market:

- ALSA, the Advanced Linux Sound Architecture, which is entirely open source
- OSS, the Open Sound System, which offers free and commercial drivers

Ubuntu uses ALSA because ALSA is the sound architecture for the 2.6 series kernels. OSS may still be found here and there, but it is no longer is widespread use and should be considered deprecated.

ALSA supports a long list of sound cards. You can review the list at www.alsa-project.org/main/index.php/Main_Page if you are interested, but Ubuntu detects most sound cards during the original installation and should detect any new additions to the system during boot up. To configure the sound card at any other time, use the sound preferences graphical tool found in the menu at System, Preferences, Sound.

In addition, Ubuntu uses an additional layer of software called PulseAudio. PulseAudio is a sound server and acts as a mediator between the various multimedia programs that have sound output and the ALSA kernel drivers. Over the years there have been many different sound servers used in Linux, each with different strengths, usability issues, and levels of documentation. These various sound servers have often been forced to run side by side on the same computer causing all sorts of confusion and issues. PulseAudio aims to replace all of them and work as a single handler to accept output from applications which use the APIs for any of the major sound servers already in use such as ESD, OSS, Gstreamer, and aRts and route the various output streams together through one handler. This gives several advantages, including the ability to control the output volume of various programs individually.

PulseAudio is still quite young and its full potential has not yet been realized; however, it has already had great improvements in the intervening releases and is better and more
powerful than ever in 10.10. Although there were stability issues and complaints in the first release that included PulseAudio, those don’t seem to be a problem anymore except in unusual hardware combinations and special cases and more and more features have been implemented. For more information about PulseAudio, please see www.pulseaudio.org/.

**Adjusting Volume**

Ubuntu offers a handy utility that you can use to control the volumes for various outputs from your computer. For a simple master volume control, just left click the speaker icon in the top-right corner of the screen and move the slider left or right, as shown in Figure 7.1.

![FIGURE 7.1](image1.png)  
**FIGURE 7.1** Control the master volume level with the volume slider.

Alternatively you can control all the output volumes for the system to make sure that you have set everything to your taste, as shown in Figure 7.2. To access the volume control, left-click the speaker icon and select Sound Preferences.

![FIGURE 7.2](image2.png)  
**FIGURE 7.2** Use the volume control to manage volume settings for all your sound output devices.
Sound Formats

A number of formats exist for storing sound recordings. Some of these formats are associated with specific technologies, and others are used strictly for proprietary reasons. Ubuntu supports several of the most popular sound formats, including:

- **raw (.raw)**—More properly known as **headerless format**, audio files using this format contain an amorphous variety of specific settings and encodings. All other sound files contain a short section of code at the beginning—a header—that identifies the format type.

- **MP3 (.mp3)**—A popular, but commercially licensed, format for the digital encoding used by many Linux and Windows applications. MP3 is not supported by any software included with Ubuntu by default but may be easily installed later. In fact, the first time you try to play an MP3 file, Ubuntu will ask if you want to install the codec needed and will help you through the whole, simple process.

- **WAV (.wav)**—The popular uncompressed Windows audio-visual sound format. It is often used as an intermediate file format when encoding audio.

- **Ogg-Vorbis (.ogg)**—Ubuntu’s preferred audio encoding format. You enjoy better compression and audio playback, and freedom from lawsuits when you use this open-source encoding format for your audio files.

- **FLAC (.flac)**—This is a lossless format popular with audiophiles. The name stands for Free Lossless Audio Format and it is a compressed format, like MP3, but does not suffer from any loss of quality.

**NOTE**

Because of patent and licensing issues, Ubuntu does not by default support the MPEG, MPEG2, and MPEG3 (MP3) file formats. Although we cannot offer any legal advice, it appears that individuals using MP3 software are okay; it is just that Ubuntu cannot distribute the code because of how the code is licensed.

You can also enable the MP3 codec within Ubuntu by downloading a plugin for gstreamer, the GNOME audio system. You do this by installing the gstreamer0.10-plugins-ugly package, which enables the MP3 codec in all the GNOME applications. Even better, there is a package called ubuntu-restricted-extras that you can install that will enable all the major formats you are ever likely to run into. The package can be found in the repositories, and as mentioned earlier in the chapter, Ubuntu will also recommend specific packages as needed when you attempt to use a file type that does not currently have an installed codec package. It really is that easy to deal with multimedia formats in Ubuntu.

Ubuntu even includes software in the repositories (such as the sox command used to convert between sound formats) so that you can more easily listen to audio files provided in a wide variety of formats, such as AU (from NeXT and Sun), AIFF (from Apple and SGI), IFF (originally from Commodore's Amiga), RA (from Real Audio), and VOC (from Creative Labs).
TIP

For an introduction to audio formats, check out the list of audio file formats at www.file-info.com/filetypes/audio with links to detailed information for each.

Ubuntu also offers several utilities for converting sound files from one format to another. Conversion utilities come in handy when you want to use a sound in a format not accepted by your current application of choice. The easiest one to use is also the easiest to install. Install the soundconverter package and then look for the application in the menu at Applications, Sound & Video, Sound Converter. It has a clear graphical interface and easy to understand configuration options.

Listening to Music

If you’re anything like we are, you might be a huge music fan. One of the downsides of having a fairly large music collection is the physical problem of having to store so many CDs. Wouldn’t it be great if you could pack them all away somewhere, yet still have access to all the music when you want it? Some manufacturers experimented with rather bulky jukeboxes that stored 250 CDs at once. The main downside with that was that finding a particular piece of music could take hours, having to cycle through each CD in the hope that it would match your mood.

Fortunately for you and me, Ubuntu is fantastic at working with CDs, even allowing you to rip all your CD collection into a vast searchable music library, letting you quickly create playlists and even giving you the ability to create your own customized CDs. Getting started couldn’t be easier, mainly because Ubuntu comes preconfigured with everything you need to get started.

Rhythmbox

Rhythmbox is a useful application that will play CDs if you insert an audio CD into your computer. It will also attempt to obtain information about the CD from the Internet. If it’s successful, you’ll see the name of the CD appear in Rhythmbox, as shown in Figure 7.3.

When you’re ready to play your CD, simply click the name of the CD under the devices section and click the Play button. You can also define whether the CD should just repeat itself until stopped, or whether you want to shuffle the music (randomize the playlist).

Of course, just listening to your CDs doesn’t really change anything. Rhythmbox acts just like a regular CD player, allowing you to listen to specific tracks and define how you want to listen to your music by using playlists or sorting it by artists. The real fun starts when you click the Copy to Library button in your toolbar. Rhythmbox then starts to extract, or rip, the audio from your CD and store it within the Music directory that is found under your home directory.

Depending on the speed of your optical drive and the power of your computer, the ripping process can take up to 15 minutes to complete a full CD. As it goes along, Rhythmbox automatically adds the files to your media library, which you can access by
clicking the Music button on the left side of the Rhythmbox screen, as you can see in Figure 7.4.

Within the Rhythmbox interface you can easily browse through the list of artist names or album titles, which affects the track listing that appears at the bottom of the screen. The numbers after each artist and album tell you how many tracks are assigned to that specific entry, giving you a heads up before you click them. Double-clicking any entry automatically starts the music playing, so for example, double-clicking an artist’s name causes the music tracks associated with that artist to start playing. When a track starts to play, Rhythmbox automatically attempts to retrieve the CD artwork, which it then displays in the bottom-left corner of the screen.

There’s a lot more that you can do with Rhythmbox, including download and listen to podcasts. A good place to start is the Ubuntu UK podcast at http://podcast.ubuntu-uk.org/. All you have to do is click an RSS link for the feed on that page, copy the link URL, and go to Rhythmbox. There, press Ctrl+P, or go to Music, New Podcast Feed, paste the link into the field, and click the Add button. Rhythmbox then contacts the server and attempts to download the most recent episodes of your chosen podcast, which you can see happening in Figure 7.5.

**Banshee**

Of course, other programs are available for listening to music within Ubuntu. A particular favorite for many is Banshee, another music application that can handle ripping and playing back music, download cover art, sync with portable players, and can even play...
FIGURE 7.4  Rhythmbox gives you a neat interface to browse through your music collection.

FIGURE 7.5  Manage your podcasts using Rhythmbox and never miss an episode again.
video. Banshee is not installed by default with Ubuntu, so you’ll need to download and install it. The package name in the Ubuntu repositories is banshee.

**GETTING MUSIC INTO UBUNTU WITH SOUND JUICER**

A handy utility that is included with Ubuntu is Sound Juicer, found under Applications, Sound and Video as the Audio CD Extractor. Sound Juicer automatically detects when you install a CD and attempt to retrieve the track details from the Internet. From there it will rip the CD tracks into Ogg files for storage on your filesystem. You can see Sound Juicer in action in Figure 7.6

![Sound Juicer](image)

**FIGURE 7.6** Create your own digital music collection with Sound Juicer.

**Buying Music in the Ubuntu One Music Store**

In Chapter 5 we mentioned Ubuntu One cloud storage. If you sign up for a free account, not only do you have the ability to store files on Ubuntu-run servers in the cloud, but you also gain access to the Ubuntu One Music Store. The store is available right inside Rhythmbox Music Player (and at the time of this writing plans were in place to add it to Banshee also). In Rhythmbox, simply click the Ubuntu One link in the window on the left of the screen to get started (Figure 7.7).

**Graphics Manipulation**

Over a very short period of time, digital cameras and digital imagery have become extremely popular, to the point where some traditional film camera manufacturers are switching solely to digital. This meteoric rise has led to an increase in the number of applications that can handle digital imagery. Linux, thanks to its rapid pace of development, is now highly regarded as a multimedia platform for editing digital images.
By default Ubuntu installs the very useful Shotwell Photo Manager (Figure 7.8) in Applications, Graphics, Shotwell Photo Manager. This application is very similar to other photo managers like iPhoto and includes simple tools that are adequate for many users such as red eye reduction, cropping, and color adjustment as well as the ability to interact with online photo hosts such as Facebook, Flickr, and Picasa.

The rest of this section discusses GIMP, a powerful graphics manipulation tool that intermediate and advanced users are likely to enjoy. You also learn about graphic file formats supported by Ubuntu, as well as some tools you can use to convert them if the application you want to use requires a different format.

**The GNU Image Manipulation Program**

One of the best graphics clients available is GIMP. GIMP is a free, GPL-licensed image editor with sophisticated capabilities that can import and export more than 30 different graphics formats, including files created with Adobe Photoshop. It is often compared with Photoshop, and GIMP represents one of the GNU Projects’ first significant successes. Many images in Linux were prepared with GIMP.

GIMP is not installed by default, but after you install it from the repositories it can be found in the menu at Applications, Graphics, GIMP Image Editor.
FIGURE 7.8 For most people, the simple tools in Shotwell Photo Manager are sufficient.

You see an installation dialog box when GIMP is started for the first time, and then a series of dialog boxes that display information regarding the creation and contents of a local GIMP directory. This directory can contain personal settings, preferences, external application resource files, temporary files, and symbolic links to external software tools used by the editor.

WHAT DOES PHOTOSHOP HAVE THAT GIMP DOES NOT?

Although GIMP is powerful, it does lack two features Adobe Photoshop offers that are important to some graphics professionals.

The first of these is the capability to generate color separations for commercial press printers (CMYK for the colors cyan, magenta, yellow, and key [or black]). GIMP uses RGB (red, green, and blue), which is great for video display, but not so great for printing presses. The second feature GIMP lacks is the use of Pantone colors (a patented color specification) to ensure accurate color matching. These deficiencies might not last long. A CMYK plug-in is in the works (an early version is available from cue.yellow-magic.info/softwares/separate-plus/index.html), and the Pantone issues are likely to be addressed in the near future as well.

If these features are unimportant to you, GIMP is an excellent tool. If you must use Adobe Photoshop, you may want to explore using Wine or Codeweavers because there have been consistent reports of success running Photoshop on Linux with these tools. Bear in mind, though, that both Ubuntu and Photoshop release regularly, so check www.winehq.org/ and www.codeweavers.com/ for the current info before assuming it will work.
After the initial configuration has finished, GIMP's main windows and toolboxes appear (Figure 7.9). GIMP's main window contains tools used for selecting, drawing, moving, viewing, enlarging or reducing, airbrushing, painting, smudging, copying, filling, and selecting color.

Using Scanners in Ubuntu

With the rise of digital photography, there has been an equal decline in the need for image scanners. However, there are still times that you want to use a scanner, and Ubuntu makes it easy with a program installed by default in the menu at Applications, Graphics, Simple Scan. Simple Scan (Figure 7.10) is designed to do one thing, scan photos or documents easily. It has few settings or options but does all the things most people would want or need.

You can also use many types of image scanners with GIMP, which is likely to be the choice of people who like to tinker with settings and options or who need greater flexibility than is offered by Simple Scan. If it wasn’t installed when you installed GIMP, install the xsane package. Then, when you scan from GIMP you will have an abundance of settings and options that you can use. You will also be able to use XSane by itself, finding it in the menu at Applications, Graphics, XSane Image Scanner.
Working with Graphics Formats

Image file formats are developed to serve a specific technical purpose (lossless compression, for example, where the file size is reduced without sacrificing image quality) or to meet a need for a proprietary format for competitive reasons. Many file formats are covered by one or more patents. For example, the GIF format had fallen into disfavor with the open-source crowd because the patent holder waited a while before deciding to enforce his patent rights rather than being upfront with requests for patent royalties.

If you want to view or manipulate an image, you need to identify the file format to choose the proper tool for working with the image. The file’s extension is your first indicator of the file’s format. The graphics image formats supported by the applications included with Ubuntu include:

- .bmp—Bitmapped graphics, commonly used in Microsoft Windows
- .gif—CompuServe Graphics Interchange Format
- .jpg—Joint Photographic Experts Group
- .pcx—IBM Paintbrush
- .png—Portable Network Graphics
- .svg—Scalable Vector Graphics
- .tif—Tagged Image File format
An extensive list of image file extensions can be found in the man page for ImageMagick, an excellent application included with Ubuntu, which you learn more about in upcoming sections of this chapter.

**TIP**

Ubuntu includes dozens of graphics conversion programs in its software repositories that are accessible through the command line as well as from a GUI, and there are few, if any, graphics file formats that cannot be manipulated when using Linux. These programs can be called in Perl scripts, shell scripts, or command-line pipes to support many types of complex format conversion and image manipulation tasks. See the man pages for the **ppm**, **pmb**, **pnm**, and **pgm** families of commands. Also see the man page for the `convert` command, which is part of a suite of extremely capable programs included with the ImageMagick suite.

Sometimes, a file you want to manipulate in some way is in a format that cannot be used by either your graphics application or the final application. The solution is to convert the image file—sometimes through several formats. The `convert` utility from ImageMagick is useful, as is the **netpbm** family of utilities. If it is not already installed, ImageMagick can be installed easily from the Ubuntu repositories; the **netpbm** tools are always installed by default. Convert is super simple to use from the command line. Here is an example:

```
matthew@seymour~:$ convert image.gif image.png
```

The `convert` utility converts between image formats recognized by ImageMagick. Color depth and size also can be manipulated during the conversion process. You can use ImageMagick to append images, surround them with borders, add labels, rotate and shade them, and perform other manipulations well suited to scripting. Other commands associated with ImageMagick include `display`, `animate`, `identify`, and `import`. The application supports more than 130 different image formats—(all listed in the man page for ImageMagick).

The **netpbm** tools are installed by default because they compose the underpinnings of graphics format manipulation. The man page for each image format lists related conversion utilities; the number of those utilities gives you some indication of the way that format is used and shows how one is built on another:

- The man page for **ppm**, the portable pixmap file format, lists 47 conversion utilities related to **ppm**. This makes sense because **ppm** or portable pixmap, is considered the lowest common denominator for color image files. It is therefore often used as an intermediate format.

- The man page for **pgm**, the portable graymap file format, lists 22 conversion utilities. This makes sense because **pgm** is the lowest common denominator for grayscale image files.

- The man page for **pnm**, the portable anymap file format, lists 31 conversion utilities related to it. However, there is no format associated with PNM because it operates in concert with **ppm**, **pgm**, and **pmb**.
An examination of the man page for `pmb`, the portable bitmap file format, reveals no conversion utilities. It’s a monochrome format and serves as the foundation of the other related formats.

The easiest way to resize or rotate image files is to install the `nautilus-image-converter` package from the repositories. This lets you right click an image when you are viewing files in the File Browser (for example, from Places > Pictures) and choose menu options to resize or rotate one or multiple images without opening another program.

### Capturing Screen Images

You can use graphics manipulation tools to capture images that are displayed on your computer screen. Although this technique was used for the production of this book, it has broader uses; there is truth to the cliché that a picture is worth a thousand words. Sometimes it is easier to show an example than it is to describe it.

A captured screen image (also called a screen grab or a screenshot) can be used to illustrate an error in the display of an application (a font problem, for example) or an error dialog that is too complex to copy down by hand. You might just want to share an image of your beautifully crafted custom desktop configuration with your friends or illustrate your written documents.

When using the default GNOME desktop, you can take advantage of the built-in screenshot mechanism (`gnome-panel-screenshot`). You can use this tool by pressing the Print Screen key. (Alt+Print Screen takes a screenshot of only the window that has focus on a desktop.) Captured images are saved in `.png` format. You can also find the tool in the menu at Applications, Accessories, Take Screenshot.

### Using Digital Cameras with Ubuntu

Most digital cameras used with Ubuntu fall into one of two categories: webcams (small, low-resolution cameras connected to the computer’s interface) or handheld digital cameras that record image data on disks or memory cards for downloading and viewing on a PC. Ubuntu supports both types. Other types of cameras, such as surveillance cameras that connect directly to a network via wired or wireless connections, need no special support (other than a network connection and viewing software) to be used with a Linux computer.

Ubuntu supports hundreds of different digital cameras, from early parallel-port (CPiA chipset-based) cameras to today’s USB-based cameras. You can even use Intel’s QX3 USB microscope with Ubuntu. The following sections describe some of the more commonly used types of still camera hardware and software supported by Ubuntu.

### Handheld Digital Cameras

Because of the good development carried out in the Linux world, you are able to plug almost any digital camera in to your computer through a USB interface, and Ubuntu automatically recognizes the camera as a USB mass storage device. You can even set
Ubuntu to recognize when a camera is plugged in so that it automatically imports your photographs for you.

**Using Shotwell Photo Manager**

Ubuntu comes by default with a pretty good photo manager called Shotwell Photo Manager (Figure 7.11) that includes simple adjustment tools. You can import your photos into Shotwell, assign tags to them, sort and arrange them, and even upload them to your favorite Internet photo hosting sites such as Facebook, Flickr, and Picasa.

![Shotwell Photo Manager](image)

**Burning CDs and DVDs in Ubuntu**

Linux is generally distributed via the Internet as disc images called ISOs that are ready to be written to CDs or DVDs. Therefore learning how to burn discs is essential if you have to download and install a Linux distribution. You can use CDs and DVDs to:

- Record and store multimedia data, such as backup files, graphics images, and music.
- Rip audio tracks from music CDs (*ripping* refers to extracting music tracks from a music CD) and compile your own music CDs for your personal use.
- Although USB storage devices such as thumb drives are making CDs and DVDs almost as rare as floppy disks, they aren’t quite gone, and many people still find them useful. As long as that remains true, we want to make sure this information is available.
Creating CDs and DVDs with Brasero

Although adequate for quick burns and use in shell scripting, the command-line technique for burning CDs and DVDs is an awkward choice for many people (but we are still going to cover doing so later in this chapter, because others find it useful and desirable). Fortunately, Ubuntu provides several graphical clients; the most useful is Brasero.

Brasero is an easy-to-use graphical CD and DVD burning application that is installed by default. You can find it in the menu at Applications, Sound & Video, Brasero Disc Burner.

Brasero takes a project-based approach to disc burning, opening up with a wizard that allows you to select from four different tasks that you’ll commonly want to do. You can see the opening screen in Figure 7.12. Brasero also remembers previous “projects,” allowing you to quickly create several copies of a disc, which is ideal if you’re planning to pass on copies of Ubuntu to your friends and family.

Burning a Data CD or DVD is as easy as selecting the option in the opening screen and dragging and dropping the files you want to include from the directory tree on the left to the drop area on the right. If you insert a blank CD or DVD in your writer, Brasero keeps an eye on the disc size, and tells you when you reach or exceed the limits. It will also create iso files, which are disc images that contain everything that would exist on the medium if you burned a real CD or DVD in one file that can be mounted by computer file systems, which is useful if you want to create multiple copies of the same disc or if you want to share a disc image, perhaps using a USB thumb drive or over the Internet.

Finally, click the Burn button, input a label for the disc, and Brasero will start creating your new CD or DVD or image file. How long it takes to create a CD or DVD depends on the amount of data you are writing and the speed of your drive.
Creating CDs from the Command Line

In Linux, creating a CD at the command line is a two-step process. You first create the ISO9660-formatted image, and you then burn or write the image onto the CD. The ISO9660 is the default file system for CD-ROMs.

Use the mkisofs command to create the ISO image. The mkisofs command has many options (see the man page for a full listing), but use the following for quick burns:

```
matthew@seymour~:$ mkisofs -r -v -J -l -o /tmp/our_special_cd.iso /source_directory
```

The options used in this example are:

- `-r`—Sets the permission of the files to more useful values. UID and GID (individual and group user ID requirements) are set to zero, all files are globally readable and searchable, and all files are set as executable (for Windows systems).
- `-v`—Displays verbose messages (rather than terse messages) so that you can see what is occurring during the process; these messages can help you resolve problems if they occur.
- `-J`—Uses the Joliet extensions to ISO9660 so that your Windows-using buddies can more easily read the CD. The Joliet (for Windows), Rock Ridge (for UNIX), and HSF (for Mac) extensions to the ISO9660 standard are used to accommodate long filenames rather than the eight-character DOS filenames that the ISO9660 standard supports.
- `-l`—Allows 31-character filenames; DOS does not like it, but everyone else does.
- `-o`—Defines the directory where the image will be written (that is, the output) and its name. The `/tmp` directory is convenient for this purpose, but the image could go anywhere you have write permissions.
- `/source_directory`—Indicates the path to the source directory; that is, the directory containing the files you want to include. There are ways to append additional paths and exclude directories (and files) under the specified path—it is all explained in the man page, if you need that level of complexity. The simple solution is to construct a new directory tree and populate it with the files you want to copy, and then make the image using that directory as the source.

Many more options are available, including options to make the CD bootable.

After you have created the ISO image, you can write it to the CD with the `cdrecord` command:

```
matthew@seymour~:$ cdrecord -eject -v speed=12 dev=0,0,0 /tmp/our_special_cd.iso
```

The options used in this example are:

- `-eject`—Ejects the CD when the write operation is finished.
- `-v`—Displays verbose messages.
- `speed=`—Sets the speed; the rate depends on the individual drive's capabilities. If the drive or the recordable medium is poor, you can use lower speeds to get a good burn.
> dev=—Specifies the device number of the CD writer (the number I told you to write down earlier).

**NOTE**

You can also use the `blank=` option with the `cdrecord` command to erase CD-RW disks. The `cdrecord` command has fewer options than `mkisofs` does, but it offers the `-multi` option, which enables you to make multisession CDs. A multisession CD enables you to write a data track, quit, and then add more data to the CD later. A single-session CD can be written to only once; any leftover CD capacity is wasted. Read about other options in the `cdrecord` man page.

Current capacity for CD media is 700MB of data or 80 minutes of music. (There are 800MB/90 minute CDs, but they are rare.) Some CDs can be overburned; that is, recorded to a capacity in excess of the standard. The `cdrecord` command and some graphical programs are capable of overburning if your CD-RW drive supports it. You can learn more about overburning CDs at www.cdmediaworld.com/hardware/cdrom/cd_oversize.shtml.

---

**Creating DVDs from the Command Line**

There are several competing formats for DVD. The formats are:

- DVD+R
- DVD-R
- DVD+RW
- DVD-RW

Differences in the + and – formats have mostly to do with how the data is modulated onto the DVD itself, with the + format having an edge in buffer underrun recovery. How this is achieved impacts the playability of the newly created DVD on any DVD player. The DVD+ format also has some advantages in recording on scratched or dirty media. Most drives support the DVD+ format. As with any technology, your mileage may vary.

We focus on the DVD+RW drives because most drives support that standard. The software supplied with Ubuntu has support for writing to DVD-R/W (rewritable) media as well. It will be useful for you to review the DVD+RW/+R/-R[W] for Linux HOWTO at http://fy.chalmers.se/~appro/linux/DVD+RW/ before you attempt to use dvd+rw-tools, which you need to install to enable DVD creation (also known as mastering) as well as the cdrtools package. You can ignore the discussion in the HOWTO about kernel patches and compiling the tools.
**TIP**

The 4.7GB size of DVD media is measured as 1000 megabytes per gigabyte, instead of the more traditionally used, but not entirely accurate, 1024 megabytes per gigabyte (more appropriately written GiB), so do not be surprised when the actual formatted capacity, about 4.4GB, is less than you anticipated. A good explanation of the difference and the need for the correction is available at http://en.wikipedia.org/wiki/Gibibyte. Most hard drive manufacturers have also made the switch. `dvd+rw-tools` does not allow you to exceed the capacity of the disk.

You need to have the `dvd+rw-tools` package installed (as well as the `cdrtools` package). The `dvd+rw-tools` package contains the `growisofs` application (that acts as a front end to `mkisofs`) as well as the DVD formatting utility.

You can use DVD media to record data in two ways. The first way is much the same as that used to record CDs in a session, and the second way is to record the data as a true file system, using packet writing.

**Session Writing**

To record data in a session, you use a two-phase process:

1. Format the disk with `dvd+rw-format /dev/scd0` (only necessary the first time you use a disk, where `/dev/scd0` is the device name for your drive).
2. Write your data to the disk with `growisofs -Z /dev/scd0 -R -J /your_files`.

The `growisofs` command simply streams the data to the disk. For subsequent sessions, use the `-M` argument instead of `-Z`. The `-Z` argument is used only for the initial session recording; if you use the `-Z` argument on an already used disk, it erases the existing files.

**CAUTION**

Some DVDs come preformatted; formatting them again when you use them for the first time can make the DVD useless. Always be sure to carefully read the packaging your DVD comes in to ensure that you are not about to create another coaster!

**TIP**

Writing a first session of at least 1GB helps maintain compatibility of your recorded data with other optical drives. DVD players calibrate themselves by attempting to read from specific locations on the disk; you need data there for the drive to read it and calibrate itself.
Also, because of limitations to the ISO9660 file system in Linux, do not start new sessions of a multisession DVD that would create a directory past the 4GB boundary. If you do so, it causes the offsets used to point to the files to “wrap around” and point to the wrong files.

Packet Writing
Packet writing treats the CD or DVD disk like a hard drive in which you create a file system (like ext3) and format the disk, and then write to it randomly as you would to a conventional hard drive. This method, although commonly available on Windows-based computers, was long considered experimental for Linux and was never used much anyway as USB thumb drives became common before the use of CD or DVD-RWs had the opportunity. We do not cover this in detail here, but a quick overview is appropriate.

TIP
DVD+RW media are capable of only about 1,000 writes, so it is very useful to mount them with the noatime option to eliminate any writing to update their inodes or simply mount them read-only when it’s not necessary to write to them.

It is possible to pipe data to the growisofs command:
```
matthew@seymour~:$ sudo your_application | growisofs -Z /dev/scd0=/dev/fd/0
```
It is also possible to burn from an existing image (or file, named pipe, or device):
```
matthew@seymour~:$ sudo growisofs -Z /dev/scd0=image
```
The dvd+rw-tools documentation, found at /usr/share/doc/dvd+rw-tools/index.html, is required reading before your first use of the program. We also suggest that you experiment with DVD-RW (rewritable) media first, as if you make mistakes then you will still be able to reuse the disk, rather than creating several new coasters for your coffee mug.

Viewing Video
You can use Ubuntu tools and applications to view movies and other video presentations on your PC. This section presents some TV and motion picture video software tools included with the Ubuntu distribution you received with this book.

TV and Video Hardware
To watch TV and video content on your PC, you must install a supported TV card or have a video/TV combo card installed. A current list of TV and video cards supported in Linux can be found at www.exploits.org/v4l/.

Freely available Linux support for TV display from video cards that have a TV-out jack is improved over a couple of years ago, but still rather poor. That support must come from the X driver, not from a video device that Video4Linux supports with a device driver. Some of the combo TV-tuner/video display cards have support, including the Matrox
Marvel, the Matrox Rainbow Runner G-Series, and the RivaTV cards. Many other combo cards lack support, although an independent developer might have hacked something together to support his own card. Your best course of action is to perform a thorough Internet search with Google.

Many of the TV-only PCI cards are supported. In Linux, however, they are supported by the video chipset they use, and not by the name some manufacturer has slapped on a generic board (the same board is typically sold by different manufacturers under different names). The most common chipset is the Brooktree Bt*** series of chips; they are supported by the bttv device driver.

If you have a supported card in your computer, it should be detected during installation. If you add it later, the hardware detection utility should detect it and configure it. It is possible to try to configure it by hand, but because the Ubuntu kernel czars try to compile every hardware option available as a module and make it available, doing so isn’t likely to be of much use. Even so, this is what you would do:

First, to determine what chipset your card has, use the `lspci` command to list the PCI device information, find the TV card listing, and look for the chipset that the card uses. For example, the `lspci` output for one computer shows

```
matthew@seymour-$: lspci
00:00.0 Host bridge: Advanced Micro Devices [AMD] AMD-760 [IGD4-1P] System Controller (rev 13)
00:01.0 PCI bridge: Advanced Micro Devices [AMD] AMD-760 [IGD4-1P] AGP Bridge
00:07.0 ISA bridge: VIA Technologies, Inc. VT82C686 [Apollo Super South] (rev 40)
00:07.1 IDE interface: VIA Technologies, Inc. VT82C586B PIPC Bus Master IDE (rev 06)
00:07.2 USB Controller: VIA Technologies, Inc. USB (rev 1a)
00:07.3 USB Controller: VIA Technologies, Inc. USB (rev 1a)
00:07.4 SMBus: VIA Technologies, Inc. VT82C686 [Apollo Super ACPI] (rev 40)
00:09.0 Multimedia audio controller: Ensoniq 5880 AudioPCI (rev 02)
00:0b.0 Multimedia video controller: Brooktree Corporation Bt878 Video Capture (rev 02)
00:0b.1 Multimedia controller: Brooktree Corporation Bt878 Audio Capture (rev 02)
00:0d.0 Ethernet controller: Realtek Semiconductor Co., Ltd. RTL-8029(AS)
00:0f.0 FireWire (IEEE 1394): Texas Instruments TSB12LV23 IEEE-1394 Controller
00:11.0 Network controller: Standard Microsystems Corp [SMC] SMC2602W EZConnect
01:05.0 VGA compatible controller: nVidia Corporation NV15 [GeForce2 Ti] (rev a4)
```

Here, the lines listing the multimedia video controller and multimedia controller say that this TV board uses a Brooktree Bt878 Video Capture chip and a Brooktree Bt878 Audio Capture chip. This card uses the Bt878 chipset. Your results will be different, depending on what card and chipset your computer has. This card happened to be an ATI All-in-Wonder VE (also known as ATI TV-Wonder). (The VE means Value Edition; hence, there is no TV-out connector and no radio chip on the card; what a value!).

Then you would figure out what module was needed, probably using Google to search for “Bt878 linux” or “Bt878 Ubuntu,” and start reading documentation. You would want to
look for official pages first rather than blog posts. Finally, you would then need to enter some information into /etc/modules.conf. This file does not exist anymore in a default Ubuntu installation, but may be created as needed and will be read at boot time. Then, you would calculate the module and kernel dependencies with `sudo depmod -a` and `sudo modprobe <module name>` to load the module. Again, this is not necessary in Ubuntu as the people doing kernel configuration create a module for everything that exists, so if it is available to them, they will make it available to you with no extra work on your part, and the system scans to see what should be loaded at boot and pulls in what is needed then.

**Video Formats**

Ubuntu recognizes a variety of video formats. The formats created by the MPEG group, Apple, and Microsoft dominate, however. At the heart of video formats are the codecs—the encoders and decoders of the video and audio information. These codecs are typically proprietary, but free codecs do exist. Here is a list of the most common video formats and their associated file extensions:

- `.mpeg`—The MPEG video format; also known as `.mpg`
- `.qt`—The QuickTime video format from Apple
- `.mov`—Another QuickTime video format
- `.avi`—The Windows audio visual format

**Viewing Video in Linux**

Out of the box, Ubuntu does not support any of the proprietary video codecs due to licensing restrictions. However this functionality can be acquired if you install the `ubuntu-restricted-extras` package from the Ubuntu software repositories. You can learn more about this at [https://help.ubuntu.com/community/RestrictedFormats](https://help.ubuntu.com/community/RestrictedFormats).

You can watch video files and video DVDs with Totem Movie Player (Figure 7.13), which is installed by default and may be found in the menu at Applications, Sound & Video, Movie Player. This may also be used with several other file formats and for both video and audio and is especially well suited for almost anything you are likely to want to use after the `ubuntu-restricted-extras` package is installed.

**ADOBE FLASH**

The Adobe Flash plug-in for the Firefox browser is a commercial multimedia application that isn’t provided with Ubuntu out of the box, but many people find it useful. Adobe Flash enables you to view Flash content at websites that support it. The easiest way of getting hold of the official version of Flash is to install the `ubuntu-restricted-extras` package. After you’ve done this, any flash animations will play quite happily within any Firefox-based browsers.

Another interesting video viewer application is VLC (Figure 7.14), which is available in the software repositories. VLC uses its own set of audio and video codecs and supports a wider
range of video formats than any other media player we have encountered. If VLC can’t play it, it probably can’t be played.

**FIGURE 7.13** Totem Movie Player works with most common video and audio formats.

**FIGURE 7.14** VLC is a powerful and capable media player.

**Personal Video Recorders**

The best reason to attach a television antenna to your computer, however, is to use the video card and the computer as a personal video recorder.

The commercial personal video recorder, TiVo, started a new trend by using Linux running on a PowerPC processor to record television programming with a variety of customizations. You can turn your computer into a personal digital video recorder with Myth TV from www.mythtv.org/, a Linux-based digital video recorder software project, made even easier for Ubuntu users by the Mythbuntu project at www.mythbuntu.org/. Everything you need is available in the Ubuntu repositories and may be installed and configured easily thanks to the people involved in these projects.
Video Editing

You can now create and edit video in Ubuntu using PiTiVi (Figure 7.15), installed by default and found in the menu at Applications, Sound & Video, PiTiVi Video Editor. You may import any video clip in any format that is supported by GStreamer, the main multimedia framework used in Ubuntu. This should include the files created by your digital camera, which should mount in Ubuntu as a storage device, making the transfer of the files from the camera to your computer quick and easy. PiTiVi lets you move scenes around, cut things, add your own soundtrack, and more.

When you install Ubuntu, by default you will use the GNOME desktop, discussed in Chapter 3. The GNOME desktop has specific strengths that appeal to many users. However, some of us have unique requirements or just like to tinker. This chapter will discuss some of the alternatives to GNOME, their strengths and weaknesses, and how to install them. This is not a complete listing of all the options available, but rather a brief survey of some of the more popular options to consider helping you get your feet wet in the realm of Linux desktop software.

**GNOME IS NOT THE ONLY OPTION**

When you install Ubuntu, you also install the GNOME desktop. However, this is neither your only option nor are you limited to only one desktop installed at a time. Each of the desktops we discuss in this chapter may be installed alongside GNOME in standard Ubuntu and you will be allowed to choose which one to use each time you log in as well as which one to use by default. This makes testing a new option less risky, because switching back to what you already know is simple.

**Desktop Environment**

A desktop environment is a graphical user interface for computers, specifically an interface that uses the idea of a physical office desk as a metaphor to make interacting with the computer simple to comprehend. As in a real-world office, a computer desktop environment will use files to
contain documents which contain information that is necessary for office tasks to be done. Computer systems take the metaphor further by adding applications, programs that allow users to create, manipulate and delete those documents as needed, much as might be done in the real world, but with greater efficiency and often with greater power.

A computer desktop will include a windowing system, another metaphoric way to deal with information that makes conceptualizing the complexity occurring behind the scenes in the digital realm easier. Files, folders (or directories), and applications open in a graphic display that may be moved around the user's desktop just as paper documents and file folders may be moved to different locations on a physical desktop for convenience and efficiency. This windowing system will include the graphical bits (called widgets) needed to draw the windows on the screen as well as all the program code needed to perform the actions desired behind the scenes while displaying those actions using the pretty metaphor. For example, moving a document from one folder to another on a desktop involves little more than a mouse click followed by a drag and drop. Behind the scenes, the desktop environment is listening to the window manager's instructions to move a file from one directory to another and then telling the window manager to draw the event on the screen as it is accomplished.

The Ubuntu software repositories include all the popular desktop environments available for Linux and make installing and trying them out easy to do. It is also possible for an adventurous person to find other desktop environments that will work on Ubuntu and download and install them. We don't cover that process here.

It is also possible to use one desktop environment while substituting a different window manager into that environment instead of using the one that comes with the desktop environment by default. For example, the standard GNOME window manager is called Metacity. It is stable and works quite well. However, Ubuntu uses a different window manager called Compiz if the installation process detects the presence of video hardware capable of taking advantage of the extra flashy features it provides (otherwise the installer configures Ubuntu to use Metacity). To make matters more interesting, you can replace either of those with other window managers such as Enlightenment (Figure 8.1), which does things in a unique and interesting manner.

In this chapter, we focus on complete desktop environments using the default window manager. In addition, because this is an Ubuntu-focused book, we focus on Ubuntu refined versions of environments such as KDE and Xfce rather than their default versions, although the default versions are also available in the Ubuntu repositories if you want to seek them out.

**KDE and Kubuntu**

The KDE project began back in 1996 with the goal of creating a quality desktop environment for the Linux desktop that was free, worked well, and which was well-integrated, meaning that programs and interfaces would have a consistent look and feel where all the parts fit together seamlessly, rather than looking like a jumbled compilation of a bunch of assorted bits.
FIGURE 8.1 Enlightment is a very unique and interesting desktop environment option.

The project has always been focused on end users rather than creating a simple GUI for the systems administrator. This is an important point, because from the beginning, the intent has been to make any computer user comfortable and able to do what they want to do without necessarily requiring a full grasp of what is happening behind the scenes. This focus continues today and is shared by other desktop environments, notably GNOME, which was started in 1997 by people once involved in the KDE project who left after a dispute over software licensing.

The cause of that dispute no longer exists as the licenses today are equivalently free, but the projects diverged a bit in their focus: GNOME seeking a desktop of zenlike simplicity with simple and elegant defaults and use while KDE pursues more flash and configuration options. Honestly, they are each great desktop environments that are well-integrated with a high degree of professionalism and quality and are easily the top two in the Linux world—try them both and see which you prefer.

Kubuntu is a project that started in the Ubuntu community very early on with the simple goal of allowing users to install and use KDE in Ubuntu. To make this even easier for people who already know they prefer KDE over GNOME, you can download an install disk for Kubuntu, which is Ubuntu minus GNOME plus KDE plus a few Kubuntu-specific enhancements. You may also install Kubuntu in standard Ubuntu and alongside GNOME by installing the kubuntu-desktop package from the Ubuntu software repositories.
Kubuntu (Figure 8.2) uses a different set of default programs for most tasks: web browsing, email, and so on. Most were written specifically for the KDE desktop environment, making KDE one of the most closely integrated and consistent Linux desktops available.

**FIGURE 8.2** The Kubuntu desktop.

**Xfce and Xubuntu**

Xfce is a lighter desktop environment that requires less memory and processing power than either GNOME or KDE and is therefore often suggested for use on older machines. It does not deserve to be relegated to that role because it also works great on current hardware and is often a quality choice for a different reason. Xfce has been developed using the traditional UNIX philosophy of software: do one thing, do it well, and play well with others.

Each part of the Xfce desktop environment is modular, you may add or remove bits at will, substitute other programs that perform the same function, and everything created by or included in Xfce is expected to work according to simple standards that allow other programs to interact with it easily.

On one hand this sometimes means that people look at Xfce and think it isn’t as seamlessly integrated and smooth as the two main desktop environments. On the other hand, it means that if you prefer the GNOME file manager (Nautilus) over the one included with Xfce (Thunar), then just install Nautilus and use it, either side by side with Thunar or remove Thunar completely. This is a huge part of what makes Xfce so lightweight, it has very few dependency requirements and is highly flexible.
Originally, Xubuntu (Figure 8.3) was designed to create a lighter weight version of Ubuntu that would run well on older hardware because of the lighter code dependencies of Xfce. Over time, some people discovered they liked the desktop environment for other reasons and the older hardware use case became less of a focus. It was the modularity of Xfce combined with a smoothness of operation that won people over and the distribution began to take some of the favored bits from Ubuntu’s customized version of GNOME and added them to Xfce to replace some of its defaults. What we have today is a very nice amalgamation of Ubuntu GNOME bits, Xfce bits, and a few other things not included by default in either.

![The Xubuntu desktop.](image)

Xubuntu still uses less memory and fewer CPU cycles than a standard Ubuntu or Kubuntu install; however, thinking of it only in those terms doesn't do it justice. To install Xubuntu with the Xfce desktop environment, install the xubuntu-desktop package.

**Ubuntu Netbook Edition**

Although Ubuntu Netbook Edition (UNE) is specifically focused on creating a version of Ubuntu ready to install and run well on small, low-powered devices, some have found its interface to be preferable to any standard desktop. For that reason, we don't want to limit your thinking and lead you to believe it is suitable only for those devices.
UNE comes with most of the same programs included that are in the standard Ubuntu installation. The main difference is that in UNE the graphical interface has been modified to save space on small screens, making this a far better option for users with small monitors.

The UNE interface is smooth and pretty, but looks different than a traditional window management system with overlapping windows of content or open programs. Here all programs open full-screen by default. There is only a top panel on the screen from which you can switch from window to window. It isn’t designed for you to drag and drop from window to another (although you can just as easily cut and paste, so real functionality is not lost), but rather to maximize the screen real estate for whatever you are using at a particular moment.

When you have no windows open or they are all minimized, UNE uses a unique menu system (Figure 8.4) that makes finding what you need easy and uses nice, large icons that are easy to view on a small screen. Most people using a netbook prefer using this interface on their computer over the standard GNOME interface. We have also met several laptop and even desktop users who use it simply because they find it more interesting, enjoyable, or beautiful.

![Figure 8.4](image.png)

**FIGURE 8.4** Ubuntu Netbook Edition uses a unique and beautiful menu system.

You can install Ubuntu Netbook Edition with the `ubuntu-netbook` package from the software repositories. If you want to do a fresh installation on a netbook, you can download it and follow the easy instructions for creating a bootable USB thumb drive (because netbooks do not include CD or DVD drives) at www.ubuntu.com/netbook/get-ubuntu/download.
LXDE and Lubuntu

The previously discussed desktop environments are all officially recognized derivatives of Ubuntu, acknowledged by the developer community and well-represented within it. This section discusses a project that is hoping to achieve that same status, but which is still quite new and experimental, Lubuntu. Lubuntu is based on LXDE.

LXDE is an extremely fast desktop environment that uses less memory and fewer CPU cycles than any of the others discussed. It is being developed specifically with lower powered computers such as netbooks in mind, but that isn’t the sole use case. For example, Knoppix, which is a Linux distribution that runs from a live, bootable CD or DVD, now uses LXDE. Knoppix is a longtime favorite of sysadmins for emergency repairs of unbootable systems as well as for its portability. It recently switched from KDE to LXDE to benefit from this lightness because running an operating system from a CD or DVD is generally much slower than when it is installed on a hard drive.

As the focus in Xubuntu turned from speed and lightness to enjoying the flexibility of Xfce, a gap was created. Users and developers interested in less-expensive hardware, such as mobile Internet devices and ARM or Mips-processor based computers, wanted to find a way to run a distribution of Linux that shared the community of Ubuntu, a beautiful and useful desktop, and that did not get bogged down on slower machines. LXDE is quite new and its development philosophy fits quite well with the hopes and dreams of these users, so it seems a perfect fit.

The Lubuntu (Figure 8.5) distribution is still very new and is not yet recommended for use as a primary desktop. The developers are working within the Ubuntu community and making consistent progress, and if you are inclined, they are also appealing for interested people to join the development team and help out. You may install `lubuntu-desktop` from the Ubuntu repositories to check out the current progress. Who knows? Maybe you will discover it is already both stable and useful enough for your needs. Even if it isn’t ready, it may excite or interest you so much that you decide to jump in and help out.
The Lubuntu desktop is quite attractive.

This page intentionally left blank
Playing games is a fun part of computing. For some of us, games are a big part of the appeal of any operating system, at least for uses beyond the business or corporate environment. From the humble card games that entertain millions during their coffee breaks, to the heavily involved first-person shooters that involve players dotted around the globe, Linux offers a quality gaming platform that may surprise you.

In this chapter we’ll explore some of the common games available for you to download and install easily in Ubuntu.

Ubuntu Gaming

A small number of games come installed by default with standard desktop Ubuntu, mostly simple things to divert your attention for a few minutes between tasks, games such as solitaire or sudoku (Figure 9.1). These are easy to try out and learn, and you may find them enjoyable.

Most of us who enjoy games will want to find something more. Thankfully, games for Linux do not stop there—several popular games have native Linux support. We will discuss a small number of our favorites here.

Emulators

In addition, there are even emulators available that enable you to play classic games, such as the LucasArts ScummVM games like Secret of Monkey Island, natively under Linux. There are emulators for DOS, NES, SNES and many more. If you are interested in them, do a search online for
Dgen/SDL, DosBox, xtrs, FCEUltra, GnGeo, SDLMama, ScummVM, and Stella. The documentation for emulators is hit or miss, but if you are lucky you may be able to play your favorite old games for consoles or operating systems that no longer exist or which current OS versions do not support.

**Installing Proprietary Video Drivers**

A major gripe of Linux users has been the difficulty involved in getting modern 3D graphics cards to work. Thankfully, both AMD (owner of the now-defunct ATI brand) and Nvidia support Linux, albeit by using closed-source drivers. This means that Ubuntu does not ship with native 3D drivers activated for either graphics card, but they are easily installed, often during or just after the operating system is installed. These drivers are needed for most of the more visually spectacular games.

Both Nvidia and AMD produce proprietary drivers, meaning that the source code is not open or available for outside developers to read or modify. Because of this it is hard for some Linux distros to include them as part of their standard installation. The Ubuntu community has taken a pragmatic approach of including both Nvidia and AMD drivers within the main Ubuntu distro, but disabled by default. That way anyone who has Nvidia or AMD hardware and wants to do so can activate those drivers to take advantage of their features.

**NOTE**

If you think that proprietary drivers are the only way on Linux, we should mention that there is a lot of development going into providing totally free and open source drivers for slightly older graphics cards. Ubuntu will automatically select the best “free” driver for your system and allow you to switch the proprietary driver should you want to. Although the open source drivers will provide 3D acceleration, this support doesn’t always extend to a full feature set or to the more recent graphics cards.
It’s very easy to activate the proprietary driver if you need to; from the menu select System, Administration, and Hardware Drivers.

Installing a different hardware driver requires super-user privileges, so a confirmation check will be run to see if you are permitted and then you will be asked for your password. After the Hardware Drivers dialog window has opened, read the descriptions and look for the recommended entry for your hardware, highlight it, and click Activate at the lower right. Ubuntu will confirm that you want to use the proprietary driver and, if you agree, will automatically download and configure the relevant driver. If you want to revert to the open driver, do the same thing, but select the activated driver and click Remove at the lower right, as shown in Figure 9.2, in the same place where the earlier Activate button was.

![Hardware Drivers dialog window](image)

**FIGURE 9.2** Use the Hardware Drivers Manager to activate or deactivate the appropriate proprietary graphics driver for your graphics card.

### Installing Games in Ubuntu

In this section we’ll take a look at how to install some of the more popular games for Ubuntu, all of which may be easily installed using Ubuntu Software Center, along with hundreds more listed in under Games. Alongside the usual shoot-‘em-up games, you’ll also find one or two strategy-focused titles.
Warsow

Warsow is a free and very fast-paced first-person shooter (FPS) game that is available on Windows, Mac OS X, and Linux. Members of the Ubuntu community have packaged the game and make it available directly and easily for Ubuntu users from the software repositories. The game involves quick movements, grabbing power ups and weapons before your enemies do, and trying to plant a bomb and steal your enemy’s flag without anyone seeing you. You can jump, dash, dodge, and even wall jump your way through out the colorful 3D environment. Figure 9.3 shows a game just getting started with lots of weapons, platforms and ramps, and power-ups in sight.

![Warsow Game Image](image)

FIGURE 9.3 Warsow is one of the newest and fastest FPS games available.

Scorched 3D

Scorched 3D is based on an old DOS game called Scorched Earth. The object and game play are similar: there are multiple players and you enter targeting details to try to destroy the other players using a variety of missile-like weapons. You earn points for each win and can buy new weapons at the end of each round. This time around, there is an amazing array of weapons available and the game play is completely in stunning 3D as seen in Figure 9.4.

Scorched 3D is based on turns. Each player shoots once, then all other players take a shot before the first player shoots again. The game allows you to have more than 20 players at the same time, including both human and computer controlled players. You may play a
local game, over a LAN, or even over the Internet. Scorched 3D also runs on Windows, Mac OS X and Linux, so you may play with your friends regardless of what platform their computer uses.

**Frozen Bubble**

Frozen Bubble is an amusing little game with sharp graphics, nice music, and easy gameplay. You may play alone or against another player. The goal is to use your colored marbles to knock down the ones above you within a certain amount of time. You have to hit at least two at a time that are the same color as the one you shoot for anything to fall; otherwise, your shot joins the menagerie above and brings your demise somewhat more quickly, as illustrated in Figure 9.5. There is a lot more to Frozen Bubble, but even with the details it is easy enough for a child to play and interesting enough to hold the interest of most adults.

**SuperTux**

Many of us grew up in the era when game play was more important than graphics. Even so, we still liked flashy and pretty looking games. SuperTux is a throwback to the Mario era. It is a 2D side scroller in which you jump, run, and occasionally shoot something if you have the appropriate power-up. This time, your hero is Tux, the Linux penguin. There are more than 25 levels available, as well as a level editor for you to create your own. If
you enjoy running, jumping, hitting your head to get money, and jumping on your enemies, this game is for you. Figure 9.6 gives you the basic look and feel.

FIGURE 9.5  Move left or right to aim, press up to fire.

FIGURE 9.6  Although the look and feel of this game takes me back to my childhood, it is far from dull or boring.
Battle for Wesnoth

One of the most popular games currently available for Linux is Battle for Wesnoth (see Figure 9.7), a strategy game featuring both single and multiplayer options. Based in a fantasy land, you are responsible for building armies to wage war against your foes who are attacking you. Game play may be based on scenarios, such as in single player mode where some scenarios are preinstalled and others may be easily downloaded, or based on trying to better your friends at a LAN party or online.

Battle for Wesnoth also comes with a map editor that lets you create your own scenarios. There is an active community that shares their work and welcomes new contributions. You will find the URL for the website in the Reference section of this chapter.

Games for Kids

Kids, both young and old, are not left out. Check out game packages such as gCompris, Childsplay, and TuxPaint to get started. Some of these are educational, some teach computer skills such as using a mouse or a keyboard, and others are just for amusement.
Many developers are also parents who have placed a high priority on making quality software for their children to enjoy on their favorite platform. You can search for children's games in the Ubuntu Software Center and find lots of great things to try.

## Playing Windows Games

Ubuntu is primarily aimed at desktop computer users who want a system that is stable, powerful, and easy to use. It is not primarily a gaming platform. In fact, compared to Windows, there are not nearly as many games available or being developed (although the number is growing and has improved) This doesn't mean hard-core gamers need to feel left out, though. There are two projects that exist to help game lovers play most Windows-based games on Linux.

A project called Wine uses application interfaces to make Windows programs believe they are running on a Windows platform and not a Linux platform. Bear in mind that Wine stands for *wine is not an emulator*, so do not start thinking of it as such—the community can get quite touchy about it!

Wine is a compatibility layer (not an emulator) that aims to make Windows software believe it is running on Windows even when it is running on Linux. Although the open-source, free software project won’t run everything, it does run a very large number of Windows programs, including many games.

Cedega is a fork of the Wine project that adds some proprietary touches and a focus on games and, for a fee, allows you to download and use their compatibility layer.

### TIP

The keys to successful gaming in Linux are to always read the documentation thoroughly, always investigate the Internet resources thoroughly, and always understand your system. Installing games is a great way to learn about your system because the reward of success is so much fun.

System administrators would have a boring, but much easier life without users. In reality, it's impossible to have a system with absolutely no users, so it is important that you learn how to effectively manage and administer your users as they work with your system. Whether you are creating a single user account or modifying a group that holds hundreds of user accounts, the fundamentals of user administration are the same.

User management and administration includes allocating and managing home directories, putting in place good password policies, and applying an effective security policy that includes things such as disk quotas and file and directory access permissions. We will take a look at all these areas within this chapter as well as some of the different types of users that you are likely to find on a typical Linux system.

**User Accounts**

You normally find three types of users on Linux systems: the super-user, the day-to-day user, and the system user. Each type is essential to the smooth running of your system. Learning the differences between the three is essential if you are to work efficiently and safely within your Linux environment.

All users who access your system must have accounts on the system. Ubuntu uses the `/etc/passwd` file to store information on the user accounts that are present on the system. All users, regardless of their type, have a one line entry in this file which contains their username (typically used for logging in to the system), an encrypted field for
the password (which contains an x to denote that a password is present), a User ID (commonly referred to as the UID) and a Group ID (commonly referred to as the GID). The last two fields show the location of the home directory (usually /home/username) and the default shell for the user (/bin/bash is the default for new users). There is also a field called GECOS that uses a comma delimited list to record information about the account or the user, most often when this is used it will record the user’s full name and contact information.

NOTE

Although the password field contains an x, this doesn’t mean that what you read here is the actual password! All passwords are stored in /etc/shadow in an encrypted format for safe keeping. Ubuntu automatically refers to this file whenever a password is required.

In keeping with long-standing tradition in UNIX-style operating systems, Ubuntu make use of the well-established UNIX file ownership and permission system. To start with, everything in these systems is treated as a file and all files (which can include directories and devices) can be assigned one or more of read, write and execute permissions. These three ‘flags’ can also be assigned as desired to each of three categories: the owner of the file, a member of a group, or anyone else on the system. The security for a file is drawn from these permissions and from file ownership. As the system administrator (also commonly referred to as the super-user) it is your responsibility to manage these settings effectively and ensure that the users have proper UIDs and GIDs. Perhaps most importantly the system administrator has the ability to lock away sensitive files from users who should not have access to them through these file permissions.

The Super-User/Root User

No matter how many system administrators there are for a system, there can only be one super-user account. The super-user account, more commonly referred to as the root user, has total and complete control over all aspects of the system. They can access any part of the file system, read, change, or delete any file, grant and revoke access to files and directories, and can carry out any operation on the system, including destroying it if they so wish. The root user is unique in that it has a UID of 0 and GID of 0.

In other words, the root user has supreme power over your system. With this in mind, it’s important that you do not work as root all the time as you may inadvertently cause serious damage to your system, perhaps even making it totally unusable. Instead, you should rely on root only when you need to make specific changes to your system that require root privileges. As soon as you’ve finished your work you can switch back to your normal user account to carry on working.

In Ubuntu you execute a command with root, or super-user, privileges using the sudo command like this:

```
matthew@seymour:~$ sudo apt-get update
```
You will then be prompted for your password, which will not show on the screen as you enter it, and press Enter. Ubuntu will then carry out the command (in this case updating information about available software) as if you were running it as root.

THE ROOT USER

If you've used other Linux distros then you may be a little puzzled by the use of the sudo command as not all distros use it. In short, Ubuntu allows the first user on the system access to full root privileges using the sudo command. It also disables the root account so no one can actually login with the username root.

In other Linux distros you change to the root user by issuing the command su – and then entering the root password when prompted. This lands you at the root prompt, which is shown as a pound sign (#). From here you are able to execute any command you wish. To get to a root prompt in Ubuntu you need to execute the command sudo -i which, after you enter your password, will give you the prompt so familiar to other Linux distros. When you’ve finished working as root just type exit and hit Enter to get back to a normal user prompt ($).

A regular user is someone who logs on to the system to use it for nonadministrative tasks such as word processing or email. These users do not need to make system wide changes or manage other users. However, they might want to be able to change settings specific to their account (for instance, a desktop background). Depending on how much control the system administrator (the root or super-user) likes to wield, regular users might not even be able to do that!

The super-user grants privileges to regular users using file and directory permissions (as covered in Chapter 4, “Command Line Quickstart”). For example, if the super-user does not want you to change your settings in ~/.profile (the ~ is a shell shortcut representing your home directory), root can alter the permissions so that you may read from, but not write to, that file.

CAUTION

Because of the potential for making a catastrophic error as the super-user, always use your system as a regular user and only use your super-user powers temporarily to do specific administration tasks. This is easier to remember in Ubuntu where the use of sudo is default and the root account is initially disabled. If you work on a multiuser system, consider this advice an absolute rule; if root were to delete the wrong file or kill the wrong process, the results could be disastrous for the system (and likely the business that owns and operates it). On your home system, you can do as you please. Running as root makes many things easier, but much less safe, and we still do not recommend doing so. In any setting, however, the risks of running as root are significant and we cannot stress how important it is to be careful when working as root.

The third type of user is the system user. The system user is not a person, but rather an administrative account that the system uses during day-to-day runnings of various
services. For example, the system user named www-data owns the Apache web server and all the associated files. Only that user and root can have access to these files—no one else can access or make changes to these files. System users do not have a home directory or password, nor do they permit access to the system through a login prompt.

You will find a list of all the users on a system in the /etc/passwd file.

**User IDs and Group IDs**

A computer is, by its very nature, a number-oriented machine. It identifies users and groups by numbers known as the *user ID (UID)* and *group ID (GID)*. The alphabetic names display on your screen just for ease of use.

As previously mentioned, the root user is UID 0. Numbers from 1 through 499 and number 65,534 are the system, sometimes called logical or psuedo users. Regular users have UIDs beginning with 1,000; Ubuntu assigns them sequentially beginning with this number.

With only a few exceptions, the GID is the same as the UID.

Ubuntu creates a private GID for every UID of 1,000 and greater. The system administrator can add other users to a GID or create a totally new group and add users to it. Unlike Windows NT and some UNIX variants, a group cannot be a member of another group in Ubuntu (or any Linux distribution).

**File Permissions**

As you learned in Chapter 4, there are three types of permissions: read, write, and execute (r, w, x). For any file or directory, permissions are assigned to three categories: user, group, and other. In this section, we will focus on group permissions. Before we do, we want to highlight three commands used to change the group, user, or access permissions of a file or directory:

- **chgrp**—Changes the group ownership of a file or directory
- **chown**—Changes the owner of a file or directory
- **chmod**—Changes the access permissions of a file or directory

These commands can be used to reproduce organizational structures and permissions in the real world in your Ubuntu system (see the next section, “Managing Groups”). For example, a human resources department can share health-benefit memos to all company employees by making the files readable (but not writable) by anyone in an accessible directory. On the other hand, programmers in the company’s research and development section, although able to access each other’s source code files, would not have read or write access to HR pay scale or personnel files (and certainly would not want HR or marketing poking around R&D).

These commands are used to easily manage group and file ownerships and permissions from the command line. It is essential that you know these commands because there are
times when you are likely to have only a command-line interface to work with; such as when a well-meaning but fat-fingered system administrator set incorrect permissions on X11 rendering the system incapable of working with a graphical interface (No, we won’t tell that story, but if you press them, most systems administrators have similar tales of woe).

USER STEREOTYPES

As is the case in many professions, exaggerated stereotypes have emerged for users and system administrators. Many stereotypes contain elements of truth mixed with generous amounts of hyperbole and humor and serve to assist us in understanding the characteristics of and differences in the stereotyped subjects. The stereotypes of the luser and the BOFH (not-so-nice terms for users and administrators, respectively) serve as cautionary tales describing what behavior is acceptable and unacceptable in the computing community.

Understanding these stereotypes allows you to better define the appropriate and inappropriate roles of system administrators, users, and others. You can find a description of each on Wikipedia at: http://en.wikipedia.org/wiki/BOFH and http://en.wikipedia.org/wiki/Luser.

Managing Groups

Groups can make managing users a lot easier. Instead of having to assign individual permissions to every user, you can use groups to grant or revoke permissions to a large number of users quickly and easily. Setting group permissions allows you to set up workspaces for collaborative working and to control what devices can be used, such as external drives or DVD writers. This approach also represents a secure method of limiting access to system resources to only those users who need them. As an example, the system administrator could put the users matthew, ryan, heather, holly, debra, and mark in a new group named unleashed. Those users could each create files intended for their group work and chgrp those files to unleashed.

Now, everyone in the unleashed group—but no one else except root—can work with those files. The system administrator would probably create a directory owned by that group so that its members could have an easily accessed place to store those files. The system administrator could also add other users such as sonya and nicole to the group and remove existing users when their part of the work is done. The system administrator could make the user matthew the group administrator so that matthew could decide how group membership should be changed. You could also put restrictions on the DVD writer so that only matthew could burn DVDs, thus protecting sensitive material from falling into the wrong hands.
Group Listing

Different UNIX operating systems implement the group concept in various ways. Ubuntu uses a scheme called *UPG (user private group)* where by default all users are assigned to a group with their own name. (The user's username and group name are identical.) All the groups on a system are listed in `/etc/group` file.

Here is a example of a portion of the `/etc/group` file:

```
matthew@seymour:~$ cat /etc/group
root:x:0:
daemon:x:1:
bin:x:2:
sys:x:3:
adm:x:4:matthew
tty:x:5:
disk:x:6:
mail:x:8:
news:x:9:
fax:x:21:matthew
voice:x:22:
cdrom:x:24:matthew
floppy:x:25:matthew
tape:x:26:matthew
www-data:x:33:
crontab:x:107:
ssh:x:109:
admin:x:115:matthew
saned:x:116:
gdm:x:119:
matthew:x:1000:
ntp:x:122:
```

In this sample you see a number of groups, mostly for services (mail, news, and so on) and devices (floppy, disk, and so on). As previously mentioned, the system services groups allow those services to have ownership and control of their files. For example, adding postfix to the mail group, as shown previously, enables the postfix application to access mail’s files in the manner that mail would decide for group access to its file. Adding a regular user to a device’s group permits the regular user to use the device with permissions granted by the group owner. Adding user *matthew* to the group cdrom, for example, allows *matthew* to use the optical drive device. You learn how to add and remove users from groups in the next section.

Group Management Tools

Ubuntu provides several command-line tools for managing groups, but also provides graphical tools for doing so. Most experienced system administrators prefer the command-line tools because they are quick and easy to use, are always available even when there is...
no graphic user interface, and because they can be included in scripts she may write if the
system administrator wants to write a quick program to perform a repetitive task.

Here are the most commonly used group management command-line tools:

- **groupadd**—This command creates and adds a new group.
- **groupdel**—This command removes an existing group.
- **groupmod**—This command creates a group name or GIDs but doesn’t add or delete
  members from a group.
- **gpasswd**—This command creates a group password. Every group can have a group
  password and an administrator. Use the `-A` argument to assign a user as group
  administrator.
- **useradd -G**—The `-G` argument adds a user to a group during the initial user creation.
  (More arguments are used to create a user.)
- **usermod -G**—This command allows you to add a user to a group so long as the user
  is not logged in at the time.
- **grpck**—This command checks the `/etc/group` file for typos.

Let’s say there is a DVD-RW device (`/dev/scd0`) on our computer that the system adminis-
trator wants a regular user named *ryan* to have permission to access. This is the process to
grant *ryan* that access:

1. Add a new group with the `groupadd` command:
   ```bash
   matthew@seymour:~$ sudo groupadd dvdrw
   ```
2. Change the group ownership of the device to the new group with the `chgrp`
   command:
   ```bash
   matthew@seymour:~$ sudo chgrp dvdrw /dev/scd0
   ```
3. Add the approved user to the group with the `usermod` command:
   ```bash
   matthew@seymour:~$ sudo usermod -G dvdrw ryan
   ```
4. Make user *ryan* the group administrator with the `gpasswd` command so that he can
   add new users to the group:
   ```bash
   matthew@seymour:~$ sudo gpasswd -A ryan
   ```

Now *ryan* has permission to use the DVD-RW drive, as would anyone else added to the
group by either the super-user or *ryan* because he is now also a group administrator and
can add users to the group.

The system administrator can also use the graphical interface that Ubuntu provides, as
shown in Figure 10.1. It is accessed from the menu at System, Administration, Users and
Groups.
Note that the full set of group commands and options are not available from the graphical interface. This limits the usefulness of the GUI to a subset of the most frequently used commands. You learn more about using the Ubuntu User Manager GUI in the next section of this chapter.

Managing Users

Users must be created, assigned a UID, provided a home directory, provided an initial set of files for their home directory, and assigned to groups so that they can use the system resources securely and efficiently. The system administrator in some situations might want or need to not only restrict a user’s access to specific files and folders, but also the amount of disk space an account may use.

User Management Tools

As with groups, Ubuntu provides several command-line tools for managing users, but also provides graphical tools for doing so. Most experienced system administrators prefer the command-line tools because they are quick and easy to use, are always available even when there is no graphic user interface, and because they can be included in scripts she may write if the system administrator wants to write a quick program to perform a repetitive task. Here are the most common commands to manage users:

- `useradd`—This command adds a new user account to the system. Its options permit the system administrator to specify the user’s home directory and initial group or to
create the user with the default home directory and group assignments (based on the new account’s username).

- **useradd** -D—This command sets the system defaults for creating the user’s home directory, account expiration date, default group, and command shell. See the specific options in `man useradd`. Used without any arguments, it displays the defaults for the system. The default set of files for a user are found in `/etc/skel`.

### NOTE

The set of files initially used to populate a new user’s home directory are kept in `/etc/skel`. This is convenient for the system administrator because any special files, links, or directories that need to be universally applied can be placed in `/etc/skel` and will be duplicated automatically with appropriate permissions for each new user.

```
matthew@seymour:$ ls -la /etc/skel
```

<table>
<thead>
<tr>
<th>Permissions</th>
<th>Owner</th>
<th>Group</th>
<th>Size</th>
<th>Date/Time</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>drwxr-xr-x</td>
<td>154 root root</td>
<td>12288</td>
<td>2010-07-01 16:30</td>
<td>..</td>
<td></td>
</tr>
<tr>
<td>-rw-r--r--</td>
<td>1 root root</td>
<td>220</td>
<td>2009-09-13 22:08</td>
<td>.bash_logout</td>
<td></td>
</tr>
<tr>
<td>-rw-r--r--</td>
<td>1 root root</td>
<td>3103</td>
<td>2010-04-18 19:15</td>
<td>.bashrc</td>
<td></td>
</tr>
<tr>
<td>-rw-r--r--</td>
<td>1 root root</td>
<td>179</td>
<td>2010-03-26 05:31</td>
<td>examples.desktop</td>
<td></td>
</tr>
<tr>
<td>-rw-r--r--</td>
<td>1 root root</td>
<td>675</td>
<td>2009-09-13 22:08</td>
<td>.profile</td>
<td></td>
</tr>
</tbody>
</table>

Each line provides the file permissions, the number of files housed under that file or directory name, the file owner, the file group, the file size, the creation date, and the filename.

As you can see, root owns every file here. The `useradd` command copies everything in `/etc/skel` to the new home directory and resets file ownership and permissions to the new user.

Certain user files might exist that the system administrator doesn’t want the user to change; the permissions for those files in `/home/username` can be reset so that the user can read them but can’t write to them.

- **userdel**—This command completely removes a user’s account (thereby eliminating that user’s home directory and all files it contains).
passwd—This command updates the “authentication tokens” used by the password management system.

**TIP**
To lock a user out of his account, use the following command:

```
matthew@seymour:-$ sudo passwd -l username
```

This prepends an ! (exclamation point, also called a bang) to the user’s encrypted password; the command to reverse the process uses the -u option.

usermod—This command changes several user attributes. The most commonly used arguments are -s to change the shell and -u to change the UID. No changes can be made while the user is logged in or running a process.

chsh—This command changes the user’s default shell. For Ubuntu, the default shell is /bin/bash, known as the Bash, or Bourne Again Shell.

### Adding New Users

The command-line approach to adding a user is quite simple and can be accomplished on a single line. In our example below, the system administrator uses the useradd command to add the new user heather. The command adduser (a variant found on some UNIX systems) is a symbolic link to useradd, so both commands work the same. In this example, we use the -p option to set the password the user requested; we use the -s to set her special shell (in place of the default bash shell), and the -u option to specify her UID. (If we create a user with the default settings, we do not need to use these options.) All we want to do can be accomplished on one line:

```
matthew@seymour:-$ sudo useradd heather -p c00kieZ4ME -s /bin/zsh -u 1042
```

The system administrator can also use the graphical interface that Ubuntu provides. You will find this in the menu at System, Administration, Users and Groups. Here, the system administrator is adding a new user to the system where user heather uses the bash command shell.

These are the steps we used to add the same account as shown in the preceding command, but using the graphical User Manager interface:

1. Launch the Ubuntu User Manager graphical interface from the menu at System, Administration, Users and Groups.
2. Click the Add User button to bring up the Add User dialog window (again, refer back to Figure 10.1).
3. Fill in the form with the new user’s name and desired username (Figure 10.2).

![Create New User](image1)

**FIGURE 10.2** Adding a new user is simple. The GUI provides a set of options for user management spread over several screens as shown here.

4. Assign a good password (Figure 10.3).

![Change User Password](image2)

**FIGURE 10.3** Change User Password.

5. Highlight the new user in the list and click Advanced Settings (Figure 10.4).
6. You may change User Privilege settings here as you like, then click the Advanced tab (Figure 10.5).

7. Open the drop down shell menu to select the desired shell (Figure 10.6).
8. Either use the arrows to the right of the User ID box to adjust the UID up or down, or assign a number greater than 1000 by entering it directly in the box. The system will prevent you from assigning a number already in use by another user account (Figure 10.7).

9. Click OK to save the settings.

Note that the user is being manually assigned the UID of 1042 because that is her UID on another machine that will be connected to this machine. Systems keep track of users by UID numbers and not by names. Even though the accounts would have the same usernames, the two machines would not recognize heather as the same user if two different UIDs were assigned.

**NOTE**

A Linux username can be any alphanumeric combination that does not begin with a special character reserved for shell script use (see Chapter 11, “Automating Tasks,” for disallowed characters, mostly <space> and punctuation characters). Usernames are often the user’s first name plus the first initial of her last name or the first initial of the user’s first name and his entire last name. These are common practices on larger systems with many users because it makes life simpler for the system administrator, but neither is a rule nor a requirement.
Monitoring User Activity on the System

Monitoring user activity is part of the system administrator’s duties and an essential task in tracking how system resources are being used. The `w` command tells the system administrator who is logged in, where he is logged in, and what he is doing. No one can hide from the super-user. The `w` command can be followed by a specific user’s name to show only that user.

The `ac` command provides information about the total connect time of a user measured in hours. It accesses the `/var/log/wtmp` file for the source of its information. The `ac` command proves most useful in shell scripts to generate reports on operating system usage for management review. Note that to use the `ac` command you will have to install the `acct` package from the Ubuntu repositories.

TIP

Interestingly, a phenomenon known as *timewarp* can occur where an entry in the `wtmp` files jumps back into the past and `ac` shows unusual amounts of time accounted for users. Although this can be attributed to some innocuous factors having to do with the system clock, it is worthy of investigation by the system administrator because it can also be the result of a security breach.

The last command searches through the `/var/log/wtmp` file and lists all the users logged in and out since that file was first created. The user reboot exists so that you might know
who has logged in since the last reboot. A companion to \texttt{last} is the command \texttt{lastb}, which shows all failed, or bad, logins. It is useful for determining whether a legitimate user is having trouble or a hacker is attempting access.

\textbf{NOTE}

The accounting system on your computer keeps track of usage user statistics and is kept in the current \texttt{/var/log/wtmp} file. That file is managed by the \texttt{init} and \texttt{login} processes. If you want to explore the depths of the accounting system, use the GNU info system: \texttt{info accounting}.

\section*{Managing Passwords}

Passwords are an integral part of Linux security, and they are the most visible part to the user. In this section, you learn how to establish a minimal password policy for your system, where the passwords are stored, and how to manage passwords for your users.

\section*{System Password Policy}

An effective password policy is a fundamental part of a good system administration plan. The policy should cover the following:

\begin{itemize}
\item Allowed and forbidden passwords
\item Frequency of mandated password changes
\item Retrieval or replacement of lost or forgotten passwords
\item Password handling by users
\end{itemize}

\section*{The Password File}

The password file is \texttt{/etc/passwd}, and it is the database file for all users on the system. The format of each line is as follows:

\begin{verbatim}
\end{verbatim}

The fields are self-explanatory except for the \texttt{gecos} field. This field is for miscellaneous information about the user, such as the user’s full name, office location, office and home phone numbers, and possibly a brief text message. For security and privacy reasons, this field is little used today, but the system administrator should be aware of its existence because the \texttt{gecos} field is used by traditional UNIX programs such as \texttt{finger} and \texttt{mail}. For that reason, it is commonly referred to as the \textit{finger information field}. The data in this field will be comma delimited; the \texttt{gecos} field can be changed with the \texttt{chfn} (change \texttt{finger}) command.

Note that a colon separates all fields in the \texttt{/etc/passwd} file. If no information is available for a field, that field is empty, but all the colons remain.
If an asterisk appears in the password field, that user will not be permitted to log on. Why does this feature exist? So that a user can be easily disabled and (possibly) reinstated later without having to be created all over again. The traditional UNIX way of accomplishing this task is for the system administrator to manually edit this field. Ubuntu provides a more elegant method with the `passwd -l` command mentioned earlier in this chapter.

Several services run as pseudo-users, usually with root permissions. These are the system, or logical, users mentioned previously. You would not want these accounts available for general login for security reasons, so they are assigned `/sbin/nologin` or `/bin/false` as their shell, which prohibits any logins from these accounts.

A list of `/etc/passwd` reveals the following (abridged for brevity):

```
matthew@seymour:-$ cat /etc/passwd
root:x:0:0:root:/root:/bin/bash
bin:x:2:2:bin:/bin:/bin/sh
sys:x:3:3:sys:/dev:/bin/sh
games:x:5:60:games:/usr/games:/bin/sh
man:x:6:12:man:/var/cache/man:/bin/sh
mail:x:8:8:mail:/var/mail:/bin/sh
news:x:9:9:news:/var/spool/news:/bin/sh
uucp:x:10:10:uucp:/var/spool/uucp:/bin/sh
www-data:x:33:33:www-data:/var/www:/bin/sh
gnats:x:41:41:Gnats Bug-Reporting System (admin):/var/lib/gnats:/bin/sh
nobody:x:65534:65534:nobody:/nonexistent:/bin/sh
messagebus:x:102:106::/var/run/dbus:/bin/false
avahi:x:105:111:Avahi mDNS daemon,,,:/var/run/avahi-daemon:/bin/false
couchdb:x:106:113:CouchDB Administrator,,,:/var/lib/couchdb:/bin/bash
haldaemon:x:107:114:Hardware abstraction layer,,,:/var/run/hald:/bin/false
kernoops:x:109:65534:Kernel Oops Tracking Daemon,,,:/bin/false
gdm:x:112:119:Gnome Display Manager:/var/lib/gdm:/bin/false
matthew:x:1000:1000:Matthew Helmke,,,:/home/matthew:/bin/bash
sshd:x:114:65534:/var/run/sshd:/usr/sbin/nologin
ntp:x:115:122::/home/ntp:/bin/false
pulse:x:111:117:PulseAudio daemon,,,:/var/run/pulse:/bin/false
```

Note that none of the password fields show a password, but rather contain an x. This is because they are shadow passwords, a useful security enhancement to Linux.

**Shadow Passwords**

It is considered a security risk to keep passwords in `/etc/passwd` because anyone with read access could run a cracking program on the file and obtain the passwords with little trouble. To avoid this risk, *shadow passwords* are used so that only an x appears in the password field of `/etc/passwd`; the real passwords are kept in `/etc/shadow`, a file that can only be read by the system administrator (and PAM, the Pluggable Authentication Modules authentication manager; see the “PAM Explained” sidebar for an explanation of PAM).
Special versions of the traditional password and login programs must be used to enable shadow passwords. Shadow passwords are automatically enabled during installation of Ubuntu.

Let’s examine an abbreviated listing of the shadow companion to /etc/passwd, the /etc/shadow file:

```
matthew@seymour:~$ sudo cat /etc/shadow
root:!:14547:0:99999:7:::
daemon:*:14544:0:99999:7:::
bin:*:14544:0:99999:7:::
sys:*:14544:0:99999:7:::
games:*:14544:0:99999:7:::
man:*:14544:0:99999:7:::
mail:*:14544:0:99999:7:::
www-data:*:14544:0:99999:7:::
irc:*:14544:0:99999:7:::
nobody:*:14544:0:99999:7:::
libuuid:!*:14544:0:99999:7:::
syslog:*:14544:0:99999:7:::
messagebus:*:14544:0:99999:7:::
kernoops:*:14544:0:99999:7:::
gdm:*:14544:0:99999:7:::
mattew:$6$wtML.mV4$.I5WeTp9tgKijJM4uLR5p6TVUqPrSvJ0N2W/t/0jVBrWQrOySEEDvXsA/sKSE1QsfmNmfPjYxVrjZ21/Ir70:14564:0:99999:7:::
sshd:*:14547:0:99999:7:::
ntp:*:14548:0:99999:7:::
usbmux:*:14724:0:99999:7:::
pulse:*:14725:0:99999:7:::
```

The fields are separated by colons and are, in order:

- The user’s login name.
- The encrypted password for the user.
- The day of which the last password change occurred, measured in the number of days since January 1, 1970. This date is known in UNIX circles as the epoch. Just so you know, the billionth second since the epoch occurred was in September 2001; that was the UNIX version of Y2K—as with the real Y2K, nothing much happened.
- The number of days before the password can be changed (prevents changing a password and then changing it back to the old password right away—a dangerous security practice).
- The number of days after which the password must be changed. This can be set to force the change of a newly issued password known to the system administrator.
- The number of days before the password expiration that the user is warned it will expire.
The number of days after the password expires that the account is disabled (for security).

Similar to the password change date, although this is the number of days since January 1, 1970 that the account has been disabled.

The final field is a “reserved” field and is not currently allocated for any use.

Note that password expiration dates and warnings are disabled by default in Ubuntu. These features are not often used on home systems and usually not even used for small offices. It is the system administrator’s responsibility to establish and enforce password expiration policies if they are to exist.

The permissions on the `/etc/shadow` file should be set so that it is not writable or readable by regular users: The permissions should be 600.

### PAM EXPLAINED

Pluggable Authentication Modules (PAM) is a system of libraries that handle the tasks of authentication on your computer. It uses four management groups: account management, authentication management, password management, and session management. This allows the system administrator to choose how individual applications will authenticate users. Ubuntu has preinstalled and preconfigured all the necessary PAM files for you.

The configuration files in Ubuntu are found in `/etc/pam.d`. These files are named for the service they control, and the format is as follows:

```
type control module-path module-arguments
```

The type field is the management group that the rule corresponds to. The control field tells PAM what to do if authentication fails. The final two items deal with the PAM module used and any arguments it needs. Programs that use PAM typically come packaged with appropriate entries for the `/etc/pam.d` directory. To achieve greater security, the system administrator can modify the default entries. Misconfiguration can have unpredictable results, so back up the configuration files before you modify them. The defaults provided by Ubuntu are adequate for home and small office users.

An example of a PAM configuration file with the formatted entries as described previously is shown next. Here are the contents of `/etc/pam.d/gdm`:

```
# %PAM-1.0
auth  requisite  pam_nologin.so
auth  required  pam_env.so readenv=1
auth  required  pam_env.so readenv=1 envfile=/etc/default/locale
auth  sufficient  pam_succeed_if.so user ingroup nopasswdlogin
@include common-auth
auth  optional  pam_gnome_keyring.so
@include common-account
```
Managing Password Security for Users

Selecting appropriate user passwords is always an exercise in trade-offs. A password such as password (do not laugh, it has been used too often in the real world and with devastating consequences) is just too easy to guess by an intruder. So are simple words or number combinations (the numbers from a street address or date of birth, for example). You would be surprised how many people use easily guessed passwords such as 123456, iloveyou, Qwerty, or abc123.

On the other hand, a password such as 2a56u'F($84u&"Hiu44Ik%$([#EJD is sure to present great difficulty to an intruder (or an auditor). However, that password is so difficult to remember that it would be likely that the password owner would write that password down on a sticky note attached to his monitor.

The system administrator has control, with settings in the /etc/shadow file, over how often the password must be changed. The settings can be changed by the super-user using a text editor, or the chage command (see man shadow and man chage for details).

Changing Passwords in a Batch

On a large system, there might be times when a large number of users and their passwords need some attention. The super-user can change passwords in a batch by using the chpasswd command, which accepts input as a name/password pair per line in the following form:

matthew@seymour:~$ sudo chpasswd username:password

Passwords can be changed en masse by redirecting a list of name and password pairs to the command. An appropriate shell script can be constructed with the information gleaned from Chapter 11.

However, Ubuntu also provides the newusers command to add users in a batch from a text file. This command also allows a user to be added to a group, and a new directory can be added for the user, too.
Granting System Administrator Privileges to Regular Users

On occasion, it may be necessary for a regular user to run a command as if they were the root user. They usually do not need these powers, but a user might on a special occasion—for example, to temporarily access certain devices or run a command for testing purposes.

There are two ways to run commands with root privileges. The first way is useful if you are the owner of both the super-user account (an enabled root account) and a regular user; the second way is useful if you are not a regular user but are not privileged to access all super-user functions (this might happen on a large, multiuser network with senior and junior administrators as well as regular users). Let's look at each.

Temporarily Changing User Identity with the `su` Command

This first scenario requires the existence of a root account, which is not enabled by default on Ubuntu systems and is not generally recommended in the Ubuntu community. However, there are times when it makes sense. Discussing that is beyond the scope of this chapter, but for the sake of argument, for the scenario and details in this section assume we are operating in one of those special cases and that a root account has been enabled.

What if you have access to an enabled root account as a super-user, but are logged on as a regular user because you are performing nonadministrative tasks, and you find you need to do something that only the super-user can do? The `su` command is available for this purpose.

NOTE

A popular misconception is that the `su` command is short for `super-user`; it really just means `substitute user`. An important but often overlooked distinction is that between `su` and `su -`. In the former instance, you become that user but keep your own environmental variables (such as paths). In the latter, you inherit the environment of that user. This is most noticeable when you use `su` to become the super-user, root. Without appending the `-`, you do not inherit the path variable that includes `/bin` or `/sbin`, so you must always enter the full path to those commands when you just `su` to `root`.

Don’t forget that on a standard Ubuntu system, the first created user is classed as root, whilst the true root account is disabled. To enable the root account you would enter the command `sudo passwd` at the command line and enter your password and a new root password. After this has been completed, you can `su` to `root`. We suggest you read this before doing so to ensure you understand the reason the root account is not enabled by default: https://help.ubuntu.com/community/RootSudo.

Because almost all Linux file system security revolves around file permissions, it can be useful to occasionally become a different user with permission to access files belonging to other users or groups or to access special files (such as the communications port `/dev/ttyS0`
when using a modem or the sound device `/dev/audio` when playing a game). You can use the `su` command to temporarily switch to another user identity, and then switch back.

The `su` command spawns a new shell, changing both the UID and GID of the existing user and automatically changes the environmental variables associated with that user, known as *inheriting the environment*. Refer to Chapter 4 for more information on environment variables.

The syntax for the `su` command is as follows:

```
matthew@seymour:~$ su option username arguments
```

The man page for `su` gives more details, but some highlights of the `su` command are here:

- `c`, `--command COMMAND`
  pass a single COMMAND to the shell with `-c`

- `m`, `--preserve-environment`
  do not reset environment variables

- `l` a full login simulation for the substituted user,
  the same as specifying the dash alone

You can invoke the `su` command in different ways that yield diverse results. By using `su` alone, you can become root, but you keep your regular user environment. This can be verified by using the `printenv` command before and after the change. Note that the working directory (you can execute `pwd` as a command line to print the current working directory) has not changed. By executing the following, you become root and inherit root's environment:

```
matthew@seymour:~$ su -
```

By executing the following, you become that user and inherit the super-user's environment—a pretty handy tool. (Remember: Inheriting the environment comes from using the dash in the command; omit that, and you keep your "old" environment.) To become another user, specify a different user's name on the command line:

```
matthew@seymour:~$ su - other_user
```

When leaving an identity to return to your usual user identity, use the `exit` command. For example, while logged on as a regular user,

```
matthew@seymour:~$ su - root
```

the system prompts for a password:

```
Password:
```

When the password is entered correctly, the root user's prompt appears:

```
root~#
```

To return to the regular user's identity, just type:

```
root~# exit
```
This takes you to the regular user's prompt:

```
matthew@seymour:~$
```

If you need to allow other users access to certain commands with root privileges, you must give them the password for the root account (often referred to as the root password) so that they can use `su`—that definitely is not a secure solution. The next section describes a more flexible and secure method of allowing normal users to perform selected root tasks and the preferred method for sharing and using super-user privileges in Ubuntu.

## Granting Root Privileges on Occasion—The `sudo` Command

It is often necessary to delegate some of the authority that root wields on a system. For a large system, this makes sense because no single individual will always be available to perform super-user functions. The problem is that UNIX permissions come with an all-or-nothing authority. Enter `sudo`, an application that permits the assignment of one, several, or all the root-only system commands.

### NOTE

As mentioned earlier, the `sudo` command is pervasive in Ubuntu, because it is used by default. If you want to get to a root shell, thereby removing the need to type `sudo` for every command, just enter `sudo -i` to get the root prompt. To return to a normal user prompt, enter `exit` and press Return. Again, this is a bit dangerous because if you are not paying attention and forget to exit root, you could cause severe damage to the system. It is usually better to choose one method or the other and use it consistently, and the Ubuntu community consistently uses and recommends using `sudo` for each command, even if it gets tedious, because it is a good reminder to think about what you are doing.

After it is configured, using `sudo` is simple. An authorized user merely precedes a super-user authority-needed command with `sudo`, like this:

```
matthew@seymour:~$ sudo command
```

When the command is entered, `sudo` checks the `/etc/sudoers` file to see whether the user is authorized to wield super-user privileges; if so, `sudo` use is authorized for a specific length of time. The user is then prompted for her password (to preserve accountability and provide some measure of security), and then the command is run as if root had issued it. During the time allotted, which is 15 minutes by default in Ubuntu, `sudo` can be used again once or multiple times without a password. If an unauthorized user attempts to execute a `sudo` command, a record of the unauthorized attempt is kept in the system log and a mail message is sent to the super-user.

Three man pages are associated with `sudo`: `sudo`, `sudoers`, and `visudo`. The first covers the command itself, the second the format of the `/etc/sudoers` file, and the third the use of the special editor for `/etc/sudoers`. You should use the special editing command because it checks the file for parse errors and locks the file to prevent others from editing it at the same time. The `visudo` command uses the `vi` editor, so you might need a quick review of
the \texttt{vi} editing commands found in Chapter 4, “Command Line Quickstart,” in the section “Working with \texttt{vi}.” You begin the editing by executing the \texttt{visudo} command with this:

```
matthew@seymour:~$ sudo visudo
```

The default /etc/sudoers file looks like this:

```
# /etc/sudoers
#
# This file MUST be edited with the 'visudo' command as root.
#
# See the man page for details on how to write a sudoers file.
#
Defaults env_reset

# Host alias specification

# User alias specification

# Cmnd alias specification

# User privilege specification

root    ALL=(ALL) ALL

# Uncomment to allow members of group sudo to not need a password
# (Note that later entries override this, so you might need to move
# it further down)
# %sudo ALL=NOPASSWD: ALL

# Members of the admin group may gain root privileges
%admin ALL=(ALL) ALL
```

The basic format of a sudoers line in the file is as follows:

```
user host_computer=command
```

The user can be an individual user or a group (a \% in front identifies a name as a group). The host_computer is normally ALL for all hosts on the network and localhost for the local machine, but the host computer can referenced as a subnet or any specific host. The command in the sudoers line can be ALL, a list of specific commands, or a restriction on specific commands (formed by prepending a \! to the command). A number of options are available for use with the sudoers line, and aliases can be used to simplify the assignment of privileges. Again, the sudoers man page will give the details, but here are a few examples:

If we add the line

```
%wheel       ALL=(ALL)       NOPASSWD: ALL
```

any user we add to the wheel group can execute any command without a password.
Suppose that we want to give a user john permission across the network to be able to add users with the graphical interface. We would add the line:

```
john ALL=/users-admin
```
or perhaps grant permission only on her local computer:

```
john 192.168.1.87=/usr/bin/users-admin
```

If we want to give the editor group system wide permission with no password required to delete files:

```
%editors ALL=NOPASSWD: /bin/rm
```

If we want to give every user permission with no password required to mount the CD drive on the localhost:

```
ALL localhost=NOPASSWD:/sbin/mount /dev/scd0 /mnt/cdrom /sbin/umount /mnt/cdrom
```

It is also possible to use wildcards in the construction of the sudoers file. Aliases can be used, too, to make it easier to define users and groups. Although the man page for sudoers contains some examples, www.komar.org/pres/sudo/toc.html provides illustrative notes and comments of sudo use at a large mythical, example company. The sudo home page at www.sudo.ws/ is also a useful resource for additional explanations and examples.

The following command presents users with a list of the commands they are entitled to use:

```
matthew@seymour:~$ sudo -l
```

**ADDING EXTRA SUDO USERS**

As mentioned earlier, by default Ubuntu grants the first created user full root access through the sudo command. If you need to add this capability for other users, you can do this easily by adding each user to the admin group or by using the User Manager tool to allow them to administer the System, which can be found in the User Privileges tab when you edit the properties for a user.

**Disk Quotas**

On large systems with many users, you often need to control the amount of disk space a user can use. Disk quotas are designed specifically for this purpose. Quotas, managed per each partition, can be set for both individual users as well as groups; quotas for the group need not be as large as the aggregate quotas for the individuals in the groups.
When files are created, both a user and a group own them; ownership of the files is always part of the metadata about the files. This makes quotas based on both users and groups easy to manage.

**NOTE**

Disk quota management is not really useful or needed on a home system and rarely, if ever, on a small office system. It is unlikely you will see or implement this in either circumstance.

To manage disk quotas, you must have the `quota` and `quotatool` packages installed on your system. Quota management with Ubuntu is not enabled by default and has traditionally been enabled and configured manually by system administrators. System administrators use the family of quota commands, such as `quotacheck` to initialize the quota database files, `edquota` to set and edit user quotas, `setquota` to configure disk quotas, and `quotaon` or `quotaoff` to control the service. (Other utilities include `warnquota` for automatically sending mail to users over their disk space usage limit.)

**Implementing Quotas**

Quotas are not enabled by default, even if the quota software package is installed on your Ubuntu system. When quotas are installed and enabled, you can see which partitions have either user quotas, group quotas, or both by looking at the fourth field in the `/etc/fstab` file. For example, one line in `/etc/fstab` shows that quotas are enabled for the `/home` partition:

```
/dev/hda5     /home    ext3        defaults,usrquota,grpquota 1 1
```

The root of the partition with quotas enabled will have the files `quota.user` or `quota.group` in them (or both files, if both types of quotas are enabled), and the files will contain the actual quotas. The permissions of these files should be `600` so that users cannot read or write to them. (Otherwise, users would change them to allow ample space for their music files and Internet art collections.) To initialize disk quotas, the partitions must be remounted. This is easily accomplished with the following:

```
matthew@seymour:~$ sudo mount -o ro,remount /partition_to_be_remounted /mount_point
```

The underlying console tools (complete with man pages) are:

- `quotaon, quotaoff`—Toggles quotas on a partition
- `repquota`—A summary status report on users and groups
quotacheck—Updates the status of quotas (compares new and old tables of disk usage); it is run after fsck

edquota—A basic quota management command

Manually Configuring Quotas

Manual configuration of quotas involves changing entries in your system’s file system table, /etc/fstab, to add the usrquota mount option to the desired portion of your file system. As an example in a simple file system, quota management can be enabled like this:

```
LABEL=/           /                ext3    defaults,usrquota        1 1
```

Group-level quotas can also be enabled by using the grpquota option. As the root operator, you must then create a file (using our example of creating user quotas) named quota.user in the designated portion of the file system, like so:

```
matthew@seymour:-$ sudo touch /quota.user
```

You should then turn on the use of quotas using the quotaon command:

```
matthew@seymour:-$ sudo quotaon -av
```

You can then edit user quotas with the edquota command to set hard and soft limits on file system use. The default system editor (vi unless you change your EDITOR environment variable) will be launched when editing a user’s quota.

Any user can find out what their quotas are with:

```
matthew@seymour:-$ quota -v
```

NOTE

Ubuntu does not support any graphical tools that enable you to configure disk quotas. A Quota mini-HOWTO is maintained at www.tldp.org/HOWTO/Quota.html.

RELATED UBUNTU COMMANDS

You will use these commands to manage user accounts in Ubuntu:

- `ac`—A user account-statistics command
- `change`—Sets or modifies user password expiration policies
- `chfn`—Creates or modifies user finger information in /etc/passwd
- `chgrp`—Modifies group memberships
- `chmod`—Changes file permissions
- `chown`—Changes file ownerships
- `chpasswd`—Batch command to modify user passwords
- `chsh`—Modifies a user’s shell
- `groups`—Displays existing group memberships
- `logname`—Displays a user’s login name
- `newusers`—Batches user management command
- `passwd`—Creates or modifies user passwords
- `su`—Executes shell or command as another user
- `sudo`—Manages selected user execution permissions
- `useradd`—Creates, modifies, or manages users
- `usermod`—Edits a user’s login profile

**Reference**

- [http://tldp.org/HOWTO/Shadow-Password-HOWTO.html](http://tldp.org/HOWTO/Shadow-Password-HOWTO.html)—The Shadow-Password HOWTO delves into the murky depths of shadow passwords and even discusses why you might not want to use them.

- [http://tldp.org/HOWTO/Security-HOWTO/](http://tldp.org/HOWTO/Security-HOWTO/)—A must-read HOWTO, the Security HOWTO is a good overview of security issues. Especially applicable to this chapter are sections on creating accounts, file permissions, and password security.

- [http://www.kernel.org/pub/linux/libs/pam/index.html](http://www.kernel.org/pub/linux/libs/pam/index.html)—The Pluggable Authentication Modules suite contains complex and highly useful applications that provide additional security and logging for passwords. PAM is installed by default in Ubuntu. It isn’t necessary to understand the intricacies of PAM to use it effectively.
In this chapter you learn about the five ways to automate tasks on your system: making tasks into services that run as your system starts, making them services you start and stop by hand, scheduling them to run at specific times, connecting multiple commands together on the shell, and writing custom scripts that group everything under one command.

After you turn on the power switch, the boot process begins with the computer executing code stored in a chip called the BIOS; this process occurs no matter what operating system you have installed. The Linux boot process begins when the code known as the boot loader starts loading the Linux kernel and ends only when the login prompt appears.

As a system administrator, you will use the skills you learn in this chapter to control your system’s services and manage runlevels on your computer. Understanding the management of the system services and states is essential to understanding how Linux works (especially in a multi-user environment) and will help untangle the mysteries of a few of your Ubuntu system’s configuration files. Furthermore, a good knowledge of the cron daemon that handles task scheduling is essential for administrators at all skill levels.

This chapter is also an introduction to the basics of creating shell scripts, or executable text files written to conform to shell syntax. Shell scripts run like any other command under Linux and can contain complex logic or a simple series of Linux command-line instructions. You can also run other shell scripts from within a shell program. The features and functions for several Linux shells are discussed in this chapter after a short introduction to working from the shell command line. You learn how to write and execute a simple
shell program using bash, one of the most popular Linux shells and the default shell in Ubuntu and most other distributions.

**Running Services at Bootup**

Although most people consider a computer to be either on or off, in Ubuntu there are a number of states in between. Known as *runlevels*, they define what system services are started upon bootup. These services are simply applications running in the background that provide some needed function to your system, such as getting information from your mouse and sending it to the display; or a service could monitor the partitions to see whether they have enough free space left on them. Services are typically loaded and run (also referred to as being started) during the boot process, in the same way as Microsoft Windows services are. Internally, Ubuntu uses a system known as Upstart instead of the classic and venerable SysVinit, but Upstart has a special backward compatibility layer that can use runlevels in the way that Linux veterans are accustomed to doing for services not otherwise handled by Upstart. There will be more on Upstart later in the chapter.

You can manage nearly every aspect of your computer and how it behaves after booting via configuring and ordering boot scripts, as well as by using various system administration utilities included with Ubuntu. In this chapter, you learn how to work with these boot scripts and system administration utilities. This chapter also offers advice for troubleshooting and fixing problems that might arise with software configuration or the introduction or removal of various types of hardware from your system.

**Beginning the Boot Loading Process**

Although the actual boot loading mechanism for Linux varies on different hardware platforms (such as the SPARC, Alpha, or PowerPC systems), Intel-based PCs running Ubuntu most often use the same mechanism throughout product lines. This process is accomplished through a basic input/output system, or BIOS. The BIOS is an application stored in a chip on the motherboard that initializes the hardware on the motherboard (and often the hardware that’s attached to the motherboard). The BIOS gets the system ready to load and run the software that we recognize as the operating system.

As a last step, the BIOS code looks for a special program known as the boot loader or boot code. The instructions in this little bit of code tell the BIOS where the Linux kernel is located, how it should be loaded into memory, and how it should be started.

If all goes well, the BIOS looks for a bootable volume such as a floppy disk, CD-ROM, hard drive, RAM disk, USB drive, or other media. The bootable volume contains a special hexadecimal value written to the volume by the boot loader application (such as Ubuntu’s default GRUB2 since Ubuntu 9.10 or GRUB in older releases, or even LILO, which some older distributions used, although LILO has never been shipped by default by Ubuntu) when the boot loader code was first installed in the system’s drives. The BIOS searches volumes in the order established by the BIOS settings (for example, USB first, followed by a DVD-ROM, and then a hard drive) and then boots from the first bootable volume it
finds. Modern BIOSs allow considerable flexibility in choosing the device used for booting the system.

**NOTE**

If the BIOS detects a hardware problem, the boot process will fail and the BIOS will generate a few beeps from the system speaker. These “beep codes” indicate the nature of the problem the BIOS has encountered. The codes vary among manufacturers, and the diagnosis of problems occurring during this phase of the boot process is beyond the scope of this book and does not involve Linux. If you encounter a problem, you should consult the motherboard manual or contact the manufacturer of the motherboard.

Next, the BIOS looks on the bootable volume for boot code in the partition boot sector also known as the Master Boot Record (MBR) of the first hard disk. The MBR contains the boot loader code and the partition table—think of it like an index for a book, plus a few comments on how to start reading the book. If the BIOS finds a boot loader, it loads the boot loader code into memory. At that point, the BIOSs job is completed, and it passes control of the system to the boot loader.

The boot loader locates the Linux kernel on the disk and loads it into memory. After that task is completed, the boot loader passes control of the system to the Linux kernel. You can see how one process builds on another in an approach that enables many different operating systems to work with the same hardware.

**NOTE**

Linux is very flexible and can be booted from multiple images on a CD-ROM, over a network using PXE (pronounced “pixie”) or NetBoot, or on a headless server with the console display sent over a serial or network connection. Work is even underway to create a special Linux BIOS at www.coreboot.org/ that will expedite the boot process because Linux does not need many of the services offered by the typical BIOS.

This kind of flexibility enables Linux to be used in a variety of ways, such as remote servers or diskless workstations, which are not generally seen in personal home use.

**Loading the Linux Kernel**

In a general sense, the kernel manages the system resources. As the user, you do not often interact with the kernel, but instead you interact with the applications that you are using. Linux refers to each application as a process, and the kernel assigns each process a number called a process ID (PID). Traditionally, the Linux kernel loads and runs a process named init, which is also known as the “ancestor of all processes” because it starts every subsequent process. Ubuntu has replaced init with Upstart, which is being written by Ubuntu developers and made available for any distribution to use, but we will walk through the traditional method first because Upstart allows for backward compatibility for those services it is not yet configured to handle. We will discuss Upstart shortly.
This next step of the boot process traditionally begins with a message that the Linux kernel is loading, and a series of messages that are printed to the screen, giving you the status of each command. A failure should display an error message. The `quiet` option may be passed to the kernel at boot time to suppress many of these messages. Ubuntu does not display these messages by default, but instead uses a boot process created by the Fedora/Red Hat developers called Plymouth that is fast and incorporates a beautiful boot screen.

If the boot process were halted at this point, the system would just sit idle and the screen would be blank. To make the system useful for users, we need to start the system services. Those services are some of the applications that allow us to interact with the system.

### System Services and Runlevels

The `init` command traditionally boots a Linux system to a specific system state, commonly referred to as its runlevel.

Runlevels determine which of the many available system services are started, as well as in which order they start. A special runlevel is used to stop the system, and a special runlevel is used for system maintenance. As you will see, there are other runlevels for special purposes.

You traditionally use runlevels to manage the system services running on a Linux computer. All these special files and scripts are set up during installation but you can change and control them manually.

### Runlevel Definitions

The runlevels are defined in a traditional Linux system in `/etc/init.d`. Some distributions use the traditional `/etc/inittab` file to manage boot services. Ubuntu has not used this for several years since Upstart has been created and is used in the boot process, so by default the file does not exist. However, if you have used one in the past and want to create one in Ubuntu, it will be read and honored. Since it is not standard in Ubuntu, we are not going to cover `/etc/inittab`.

Each runlevel tells the `init` command what services to start or stop. Although runlevels might all have custom definitions, Ubuntu has adopted some standards for runlevels:

- **Runlevel 0**—Known as “halt,” this runlevel is used to shut down the system.
- **Runlevel 1**—This is a special runlevel, defined as “single,” which boots Ubuntu to a root access shell prompt where only the root user may log in. It has networking, X, and multi-user access turned off. This is the maintenance or rescue mode. It allows the system administrator to perform work on the system, make backups, or repair configuration or other files.
- **Runlevel 2**—This is the default runlevel for Ubuntu.
- **Runlevels 3–5**—These runlevels aren’t used in Ubuntu but are often used in other Linux distributions.
- **Runlevel 6**—This runlevel is used to reboot the system.
Runlevel 1 (also known as single-user mode or maintenance mode) is most commonly used to repair file systems and change the root password on a system when the password has been forgotten. Trespassers with physical access to the machine can also use runlevel 1 to access your system.

**CAUTION**

Never forget that uncontrolled physical access is virtually a guarantee of access to your data by an intruder.

### Booting into the Default Runlevel

Ubuntu boots into runlevel 2 by default, which means it starts the system as normal and leaves you inside the X Window System looking at the Gnome login prompt. It knows what runlevel 2 needs to load by looking in the rc*.d directories in /etc. Ubuntu contains directories for rc0.d through to rc5.d and rcS.d.

Assuming that the value is 1, the rc script then executes all the scripts under the /etc/rc.1 directory and then launches the graphical login.

If Ubuntu is booted to runlevel 1, for example, scripts beginning with the letter K followed by scripts beginning with the letter S under the /etc/rc1.d directory are then executed:

```
matthew@seymour:~$ ls /etc/rc1.d/
K10jackd        K20rsync             K20vboxdrv   K80cups      S70pppd-dns
K15pulseaudio   K20saned             K20winbind   README       S90single
K20acpi-support K20saslauthd         K74bluetooth S30killprocs
K20kerneloops   K20speech-dispatcher K77ntp       S70dns-clean
```

These scripts, as with all scripts in the rc*.d directories, are actually symbolic links to system service scripts that reside in the /etc/init.d directory.

The rc1.d links are prefaced with a letter and number, such as K15 or S10. The (K) or (S) in these prefixes indicate whether or not a particular service should be killed (K) or started (S) and pass a value of stop or start to the appropriate /etc/init.d script. The number in the prefix executes the specific /etc/init.d script in a particular order. The symlinks have numbers to delineate the order in which they are started. Nothing is sacred about a specific number, but some services need to be running before others are started. You would not want your Ubuntu system to attempt, for example, to mount a remote Network File System (NFS) volume without first starting networking and NFS services.

### Understanding init Scripts and the Final Stage of Initialization

Each /etc/init.d script, or init script, contains logic that determines what to do when receiving a start or stop value. The logic might be a simple switch statement for execution, as in this example:

```bash
case "$1" in
```
Although the scripts can be used to customize the way that the system runs from power-on, absent the replacement of the kernel, this script approach also means that the system does not have to be halted in total to start, stop, upgrade, or install new services.

Note that not all scripts will use this approach, and that other messages might be passed to the service script, such as restart, reload, or status. Also, not all scripts will respond to the same set of messages (with the exception of start and stop, which they all have to accept by convention) because each service might require special commands.

After all the system scripts have been run, your system is configured and all the necessary system services have been started. If you are using a runlevel other than 5, the final act of the init process is to launch the user shell—bash, tcsh, zsh, or any of the many command shells available. The shell launches and you see a login prompt on the screen.

### Controlling Services at Boot with Administrative Tools

You can configure what services run at startup from the menus at System, Preferences, Startup Applications (shown in Figure 11.1). Here Ubuntu lists all the services that you can have automatically start at boot time. They are usually all enabled by default, but you can uncheck the ones you don’t want and click OK. It is not recommended that you disable services randomly “to make things go faster.” Some services might be vital for the contin-
Beginning the Boot Loading Process

uing operation of your computer, such as the graphical login manager and the system communication bus.

![Startup Applications Preferences](image)

**FIGURE 11.1** You can enable and disable Ubuntu’s bootup services by toggling the check boxes in the Services dialog.

### Changing Runlevels

After making changes to system services and runlevels, you can use the `telinit` command to change runlevels on-the-fly on a running Ubuntu system. Changing runlevels this way allows system administrators to alter selected parts of a running system to make changes to the services or to put changes into effect that have already been made (such as reassignment of network addresses for a networking interface).

For example, a system administrator can quickly change the system to maintenance or single-user mode by using the `telinit` command with its `S` option like this:

```
matthew@seymour:-$ sudo telinit S
```

The `telinit` command uses the `init` command to change runlevels and shut down currently running services.

After booting to single-user mode, you can then return to multi-user mode, like this:

```
matthew@seymour:-$ sudo telinit 2
```

**TIP**

Linux is full of shortcuts: If you exit the single-user shell by typing `exit` at the prompt, you will go back to the default runlevel without worrying about using `telinit`.

Troubleshooting Runlevel Problems

Reordering or changing system services during a particular runlevel is rarely necessary when using Ubuntu unless some disaster occurs. But system administrators should have a basic understanding of how Linux boots and how services are controlled in order to perform troubleshooting or to diagnose problems. By using additional utilities such as the dmesg | less command to read kernel output after booting or by examining system logging with cat /var/log/messages | less, it is possible to gain a bit more detail about what is going on when faced with troublesome drivers or service failure.

To better understand how to troubleshoot service problems in Ubuntu, look at the diagnosis and resolution of a typical service-related issue.

In this example, X will not start: You don’t see a desktop displayed, nor does the computer seem to respond to keyboard input. The X server might either be hung in a loop, repeatedly failing, or might exit to a shell prompt with or without an error message.

The X server only attempts to restart itself in runlevel 2, so to determine whether the X server is hung in a loop, try switching to runlevel 1.

TIP

If you are working on a multi-user system and might inadvertently interrupt the work of other users, first ask them to save their current work, then change to a safer runlevel, such as single user mode.

Change to runlevel 1 by running the command **telinit 1. This switch to runlevel 1 will stop the X server from attempting to restart itself.**

Now you can easily examine the error and attempt to fix it.

First, try to start the X server “naked” (without also launching the window manager). If you are successful, you will get a gray screen with a large X in the middle. If so, kill X with the Ctrl+Alt+Backspace key combination, and look at your window manager configuration. (This configuration varies according to which window manager you have chosen.)

Let us assume that X won’t run “naked.” If we look at the log file for Xorg (it’s clearly identified in the /var/log directory), we’ll pay attention to any line that begins with (EE), the special error code. We can also examine the error log file, .xsessions-error, in our home directory if such a file exists.

If we find an error line, the cause of the error might or might not be apparent to us. The nice thing about the Linux community is that it is very unlikely that you are the first person to experience that error. Enter the error message (or better, a unique part of it) into www.google.com/linux and discover what others have had to say about the problem. You might need to adjust your search to yield usable results, but that level of detail is beyond the scope of this chapter. Make adjustments and retest as before until you achieve success.

Fix the X configuration and start X with **startx. Repeat as necessary.**
CAUTION

Before making any changes to any configuration file, always make a backup copy of the original, unmodified file. Our practice is to append the extension .original to the copy because that is a unique and unambiguous identifier.

If you need to restore the original configuration file, do not rename it, but copy it back to its original name.

Starting and Stopping Services Manually

If you change a configuration file for a system service, it is usually necessary to stop and restart the service to make it read the new configuration. If you are reconfiguring the X server, it is often convenient to change from runlevel 2 to runlevel 1 to make testing easier and then switch back to runlevel 2 to re-enable the graphical login. If a service is improperly configured, it is easier to stop and restart it until you have it configured correctly than it is to reboot the entire machine.

The traditional way to manage a service (as root) is to call the service’s /etc/init.d name on the command line with an appropriate keyword, such as start, status, or stop. For example, to start the Apache web server, call the /etc/init.d/apache2 script like this:

```
sudo /etc/init.d/apache2 start
Starting apache 2.2 web server                                    [ OK ]
```

The script will execute the proper program(s) and report the status of it. Stopping services is equally easy, using the stop keyword.

Using Upstart

Upstart was originally developed for Ubuntu. It is currently in use by a growing number of distributions including Fedora (9 and later), Nokia’s Maemo platform, and Google’s Chrome OS. Upstart is an event based replacement for the /sbin/init daemon and System-V init system. It handles starting of tasks and services during boot and stops them during shutdown. It also supervises them while the system is running and is intended to become a way to have tasks and services start or stop automatically based on specific events that happen rather than having to call a script manually to start or stop them. This is a big change and a big deal because it will make the overall system much more flexible, configurable, and responsive to conditions.

Basically, in Upstart, tasks and services are started and stopped by events. Events are generated as other tasks and services are started and stopped and may be received from any other process on the system. Services may be respawned if they die unexpectedly and communication with the init daemon occurs over D-Bus. Planned features that have not yet been implemented include the ability for events to be created at timed intervals or at scheduled times or as files or directories are changed and the creation of user services that users can start and stop themselves. This means that eventually Upstart jobs could even...
replace the venerable `cron` as well as do things previously impossible on any UNIX or Linux version!

For now, Upstart is being used for boot and shutdown and not all services have Upstart jobs written. Those that exist reside as expected in `/etc/init` and are easily accessible in the same basic manner as init jobs. If an Upstart job exists and you try to manage it using the traditional method, you will get a message like this:

```
matthew@seymour:~$ sudo /etc/init.d/ufw stop
```

Rather than invoking init scripts through `/etc/init.d`, use the `service` utility, e.g. `service ufw stop`. Because the script you are attempting to invoke has been converted to an Upstart job, you may also use the `stop` utility, e.g. `stop ufw`.

In this case, to start or stop Ubuntu's Uncomplicated Firewall (UFW), you just enter:

```
sudo start ufw
```
or

```
sudo stop ufw
```

Upstart is still quite new and in heavy development. Not much documentation exists and this is on purpose. Processes and features are not yet set in stone, so while the foundation is being extended the development team felt it best to keep the details a bit muddy to keep information that is changing quickly from propagating and requiring a ton of work or making it impossible to fix or replace incorrect or changed information later in the public knowledgebase. If you want to learn more about Upstart, start with http://upstart.ubuntu.com/. More details are expected to be released as development continues, but if you are the impatient type who loves to play with the latest shiny toy and aren’t afraid of getting your hands dirty, then with some digging you should be able to find what you want or need using the website and the examples already installed on your computer.

### Scheduling Tasks

There are three ways to schedule commands in Ubuntu, all of which work in different ways. The first is the `at` command, which specifies a command to run at a specific time and date relative to today. The second is the `batch` command, which is actually a script that redirects you to the `at` command with some extra options set so your command runs when the system is quiet. The last option is the `cron` daemon, which is the Linux way of executing tasks at a given time.

### Using `at` and `batch` to Schedule Tasks for Later

If there is a time-intensive task you want to run, but you do not want to do it while you are still logged in, you can tell Ubuntu to run it later with the `at` command. To use `at`, you need to tell it the time at which you want to run and then press Enter. You will then see a new prompt that starts with `at>`, and everything you type there until you press `Ctrl+D` will be the commands you want `at` to run.
When the designated time arrives, at will perform each action individually and in order, which means later commands can rely on the results of earlier commands. In this next example, run at just after 5 p.m., at is used to download and extract the latest Linux kernel at a time when the network should be quiet:

```
matthew@seymour:~$ at now + 7 hours
at> wget http://www.kernel.org/pub/linux/kernel/v2.6/linux-2.6.10.tar.bz2
at> tar xvfjlp linux-2.6.10.tar.bz2
at> <EOT>
job 2 at 2010-07-08 20:01
```

Specifying `now + 7 hours` as the time does what you would expect: at was run at 8 p.m., so the command will run just after 3 a.m.

If you have a more complex job, you can use the `-f` parameter to have at read its commands from a file, like this:

```
echo wget http://www.kernel.org/pub/linux/kernel/v2.6/linux-2.6.10.tar.bz2\;
tar xvfjlp linux-2.6.10.tar.bz2 > myjob.job
at -f myjob.job tomorrow
```

As you can see, at is flexible about the time format it takes; you can specify it in three ways:

- Using the `now` parameter, you can specify how many minutes, hours, days, or weeks relative to the current time—for example, `now + 4 weeks` would run the command one month from today.

- You can also specify several special times, including `tomorrow`, `midnight`, `noon`, or `teatime` (4 p.m.). If you do not specify a time with `tomorrow`, your job is set for precisely 24 hours from the current time.

- You can specify an exact date and time using `HH:MM MM/DD/YY` format—for example, `16:40 22/12/10` for 4:40 p.m. on the 22nd of December 2010.

When your job is submitted, at will report the job number, date, and time that the job will be executed; the queue identifier; plus the job owner (you). It will also capture all your environment variables and store them along with the job so that, when your job runs, it can restore the variables, preserving your execution environment.

The job number and job queue identifier are both important. When you schedule a job using at, it is placed into queue “a” by default, which means it runs at your specified time and takes up a normal amount of resources.

There is an alternative command, batch, which is really just a shell script that calls at with a few extra options. These options `(-q b -m now, if you were interested)` set at to run on queue b `(-q b)`, mailing the user on completion `(-m)`, and running immediately `(-now)`. The queue part is what is important: Jobs scheduled on queue b will only be executed when system load falls below 0.8—that is, when the system is not running at full load.
Furthermore, it will run with a lower niceness, meaning a queue jobs usually have a niceness of 2, whereas b queue jobs have a niceness of 4.

Because batch always specifies now as its time, you need not specify your own time; it will simply run as soon as the system is quiet. Having a default niceness of 4 means that batched commands will get less system resources than a queue job's (at's default) and less system resources than most other programs. You can optionally specify other queues using at. Queue c runs at niceness 6, queue d runs at niceness 8, and so on. However, it is important to note that the system load is only checked before the command is run. If the load is lower than 0.8, your batch job will be run. If the system load subsequently rises beyond 0.8, your batch job will continue to run, albeit in the background, thanks to its niceness value.

When you submit a job for execution, you will also be returned a job number. If you forget this or just want to see a list of other jobs you have scheduled to run later, use the atq command with no parameters. If you run this as a normal user, it will print only your jobs; running it as a super-user will print everyone's jobs. The output is in the same format as when you submit a job, so you get the ID number, execution time, queue ID, and owner of each job.

If you want to delete a job, use the atrm command followed by the ID number of the job you want to delete. This next example shows atq and atrm being used to list jobs and delete one:

```
matthew@seymour:~$ atq
14 2010-01-20 23:33 a matthew
16 2010-02-03 22:34 a matthew
17 2010-01-25 22:34 a matthew
15 2010-01-22 04:34 a matthew
18 2010-01-22 01:35 b matthew
matthew@seymour:~$ atrm 16
matthew@seymour:~$ atq
14 2010-01-20 23:33 a matthew
17 2010-01-25 22:34 a matthew
15 2010-01-22 04:34 a matthew
18 2010-01-22 01:35 b matthew
```

In that example, job 16 is deleted using atrm, and so it does not show up in the second call to atq.

The default configuration for at and batch is to allow everyone to use it, which is not always the desired behavior. Access is controlled through two files: /etc/at.allow and /etc/at.deny. By default, at.deny exists but is empty, which allows everyone to use at and batch. You can enter usernames into at.deny, one per line, to stop those users scheduling jobs.

Alternatively, you can use the at.allow file; this does not exist by default. If you have a blank at.allow file, no one except root is allowed to schedule jobs. As with at.deny, you can add usernames to at.allow one per line, and those users will be able to schedule jobs. You should use either at.deny or at.allow: When someone tries to run at or batch,
Ubuntu checks for her username in `at.allow`. If it is in there, or if `at.allow` does not exist, Ubuntu checks for her username in `at.deny`. If her username is in `at.deny` or `at.deny` does not exist, she is not allowed to schedule jobs.

**Using cron to Run Jobs Repeatedly**

The `at` and `batch` commands work well if you just want to execute a single task at a later date, but they are less useful if you want to run a task frequently. Instead, the `crond` daemon exists for running tasks repeatedly based upon system—and user—requests. Cron has a similar permissions system to `at`: Users listed in the `cron.deny` file are not allowed to use Cron, and users listed in the `cron.allow` file are. An empty `cron.deny` file—the default—means everyone can set jobs. An empty `cron.allow` file means that no one (except root) can set jobs.

There are two types of jobs: system jobs and user jobs. Only root can edit system jobs, whereas any user whose name appears in `cron.allow` or does not appear in `cron.deny` can run user jobs. System jobs are controlled through the `/etc/crontab` file, which by default looks like this:

```plaintext
SHELL=/bin/sh
PATH=/usr/local/sbin:/usr/local/bin:/sbin:/bin:/usr/sbin:/usr/bin

# m h dom mon dow user   command
17 *   *   *   *   root    cd / && run-parts —report /etc/cron.hourly
25 6   *   *   *   root    test -x /usr/sbin/anacron || ( cd / && run-parts —report
/etc/cron.daily )
47 6   *   *   7   root    test -x /usr/sbin/anacron || ( cd / && run-parts —report
/etc/cron.weekly )
52 6   1   *   *   root    test -x /usr/sbin/anacron || ( cd / && run-parts —report
/etc/cron.monthly )
```

The first two lines specify which shell should be used to execute the job (defaults to the shell of the user who owns the `crontab` file, usually `/bin/bash`), and the search path for executables that will be used. It’s important that you avoid using environment variables in this path statement, because they may not be set when the job runs.

The next line starts with a pound sign (`#`) and so is treated as a comment and ignored. The next four lines are the important parts: They are the jobs themselves.

Each job is specified in seven fields that define the time to run, owner, and command. The first five commands specify the execution time in quite a quirky order: minute (0–59), hour (0–23), day of the month (1–31), month of the year (1–12), and day of the week (0–7). For day of the week, both 0 and 7 are Sunday, which means that 1 is Monday, 3 is Wednesday, and so on. If you want to specify “all values” (that is, every minute, every hour, every day, and so on), use an asterisk, `*`.

The next field specifies the username of the owner of the job. When a job is executed, it uses the username specified here. The last field is the command to execute.
So, the first job runs at minute 17, every hour of every day of every month and executes the command `run-parts /etc/cron.hourly`. The `run-parts` command is a simple script that runs all programs inside a given directory—in this case, `/etc/cron.hourly`. So, in this case, the job will execute at 00:17 (17 minutes past midnight), 01:17, 02:17, 03:17, and so on, and will use all the programs listed in the `cron.hourly` directory.

The next job runs at minute 25 and hour 6 of every day of every month, running `run-parts /etc/cron.daily`. Because of the hour limitation, this script will run only once per day, at 6:25 a.m. Note that it uses minute 25 rather than minute 17 so that daily jobs do not clash with hourly jobs. You should be able to guess what the next two jobs do, simply by looking at the commands they run!

Inside each of those four directories (`cron.hourly`, `cron.daily`, `cron.weekly`, and `cron.monthly`) are a collection of shell scripts that will be run by `run-parts`. For example, in `cron.daily` you will have scripts like `logrotate`, which handles backing up of log files, and `makewhatis`, which updates the `whatis` database. You can add other system tasks to these directories if you want to, but you should be careful to ensure your scripts are correct.

---

**CAUTION**

The `cron` daemon reads all the system `crontab` files and all user `crontab` files once a minute (on the minute, i.e. at 6:00:00, 6:01:00, and so on) to check for changes. However, any new jobs it finds will not be executed until at least 1 minute has passed.

For example, if it is 6:01:49 (that is, 49 seconds past 1 minute past 6 a.m.) and you set a `cron` job to run at 6:02, it will not execute. At 6:02, the `cron` daemon will reread its configuration files and see the new job, but it will not be able to execute it. If you set the job to run at 6:02 a.m. every day, it will be executed the following morning and every subsequent morning.

This same situation exists when deleting jobs. If it is 6:01:49 and you have a job scheduled to run at 6:02, deleting it will make no difference: `cron` will run it before it rereads the `crontab` files for changes. However, after it has reread the `crontab` file and noticed the job is no longer there, it will not be executed in subsequent days.

---

There are alternative ways of specifying dates. For example, you can use sets of dates and times by using hyphens of commas, such as hours 9–15 would execute at 9, 10, 11, 12, 13, 14, and 15 (from 9 a.m. to 3 p.m.), whereas 9, 11, 13, 15 would miss out at the even hours. Note that it is important you do not put spaces into these sets because the `cron` daemon will interpret them as the next field. You can define a step value with a slash (/) to show time division: */4 for hours means “every four hours all day,” and 0-12/3 means “every three hours from midnight to noon.” You can also specify day and month names rather than numbers, using three-character abbreviations: Sun, Mon, Tue, Fri, Sat for days, or Jan, Feb, Mar, Oct, Nov, Dec for months.

As well as system jobs, there are also user jobs for those users who have the correct permissions. User jobs are stored in the `/var/spool/cron` directory, with each user having his own file in his named after his username—for instance, `/var/spool/cron/matthew` or...
/var/spool/cron/root. The contents of these files contain the jobs the user wants to run and take roughly the same format as the /etc/crontab file, with the exception that the owner of the job should not be specified because it will always be the same as the filename.

To edit your own crontab file, type crontab –e. This brings up a text editor (vim by default, but you can set the EDITOR environment variable to change that) where you can enter your entries. The format of this file is a little different from the format for the main crontab because this time there is no need to specify the owner of the job—it is always you.

So, this time each line is made up of six fields: minute (0–59), hour (0–23), day of the month (1–31), month of the year (1–12), day of the week (0–7), and then the command to run. If you are using vim and are new to it, press i to enter insert mode to edit your text; then press Esc to exit insert mode. To save and quit, type a colon followed by wq and press Enter.

When programming, we tend to use a sandbox subdirectory in our home directory where we keep all sorts of temporary files that we were just playing around with. We can use a personal job to empty that directory every morning at 6 a.m. so that we get a fresh start each morning. Here is how that would look in our crontab file:

```
0 6 * * * rm –rf /home/matthew/sandbox/*
```

If you are not allowed to schedule jobs, you will be stopped from editing your crontab file.

After your jobs are placed, you can use the command crontab –l to list your jobs. This just prints the contents of your crontab file, so its output will be the same as the line you just entered.

If you want to remove just one job, the easiest thing to do is type crontab –e to edit your crontab file in vim; then, after having moved the cursor to the job you want to delete, type dd (two ds) to delete that line. If you want to delete all your jobs, you can use crontab –r to delete your crontab file.

---

**Basic Shell Control**

Ubuntu includes a rich assortment of capable, flexible, and powerful shells. Each shell is different but has numerous built-in commands and configurable command-line prompts and might include features such as command-line history, the ability to recall and use a previous command line, and command-line editing. As an example, the bash shell is so powerful that it is possible to write a minimal web server entirely in bash’s language using 114 lines of script (see the link at the end of this chapter).

Although there are many shells to choose from, most people stick with the default, bash. This is because bash does everything most people need to do, and more. Only change your shell if you really need to.
Table 11.1 lists each shell, along with its description and location, in your Ubuntu file system.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>bash</td>
<td>The Bourne Again SHell</td>
<td>/bin/bash</td>
</tr>
<tr>
<td>ksh</td>
<td>The Korn shell</td>
<td>/bin/ksh, /usr/bin/ksh</td>
</tr>
<tr>
<td>pdksh</td>
<td>A symbolic link to ksh</td>
<td>/usr/bin/pdksh</td>
</tr>
<tr>
<td>rsh</td>
<td>The restricted shell (for network operation)</td>
<td>/usr/bin/rsh</td>
</tr>
<tr>
<td>sh</td>
<td>A symbolic link to bash</td>
<td>/bin/sh</td>
</tr>
<tr>
<td>tcsh</td>
<td>A csh-compatible shell</td>
<td>/bin/tcsh</td>
</tr>
<tr>
<td>zsh</td>
<td>A compatible csh, ksh, and sh shell</td>
<td>/bin/zsh</td>
</tr>
</tbody>
</table>

**LEARNING MORE ABOUT YOUR SHELL**

All the shells listed in Table 11.1 have accompanying man pages, along with other documentation under the /usr/share/doc directory. Some of the documentation can be quite lengthy, but it is generally much better to have too much documentation than too little! The bash shell includes more than 100 pages in its manual, and the zsh shell documentation is so extensive that it includes the zshall meta man page (use man zshall to read this overview)!

**The Shell Command Line**

Having a basic understanding of the capabilities of the shell command line can help you write better shell scripts. If, after you have finished reading this short introduction, you want to learn more about the command line, check out Chapter 35, “Command Line Masterclass.” You can use the shell command line to perform a number of different tasks, including:

- Searching files or directories with programs using pattern-matching, or expressions; these commands include the GNU gawk (linked as awk) and the grep family of commands, including egrep and fgrep.
- Getting data from and sending data to a file or command, known as input and output redirection.
- Feeding or filtering a program’s output to another command (called using pipes).

A shell can also have built-in job-control commands to launch the command line as a background process, suspend a running program, selectively retrieve or kill running or suspended programs, and perform other types of process control.
Multiple commands can be run on a single command line using a semicolon to separate commands:

```
matthew@seymour:-$ w ; free ; df
```

```
18:14:13 up 4:35, 2 users, load average: 0.97, 0.99, 1.04
USER TTY FROM LOGIN@ IDLE JCPU PCPU WHAT
matthew tty7 :0 13:39 4:35m 24:34 0.32s gnome-session
matthew pts/0 :0.0 17:24 0.00s 1.19s 4.98s gnome-terminal
```

```
total used free shared buffers cached
Mem: 4055692 1801104 2254588 0 134096 757532
```

```
USER TTY FROM LOGIN@ IDLE JCPU PCPU WHAT
matthew tty7 :0 13:39 4:35m 24:34 0.32s gnome-session
matthew pts/0 :0.0 17:24 0.00s 1.19s 4.98s gnome-terminal
```

```
/dev/sda1 14421344 6509276 7179508 48% /
none 2020136 336 2019800 1% /dev
none 2027844 3004 2024840 1% /dev/shm
none 2027844 224 2027620 1% /var/run
none 2027844 0 2027844 0% /var/lock
none 2027844 0 2027844 0% /lib/init/rw
/dev/sda6 284593052 144336704 125799860 54% /home
```

This example displays the output of the `w`, `free`, and `df` commands. Long shell command lines can be extended inside shell scripts or at the command line by using the backslash character (`\`). For example,

```
matthew@seymour:-$ echo "this is a long "
> command line and" ; echo "shows that multiple commands"
> may be strung out."
```

```
this is a long command line and
shows that multiple commands may be strung out.
```

The first three lines of this example are a single command line. In that single line are two instances of the echo command. Note that when you use the backslash as a line-continuation character, it must be the last character on the command line (or in your shell script, as you will see later on in this chapter).

Using the basic features of the shell command line is easy, but mastering use of all features can be difficult. Entire books have been devoted to using shells, writing shell scripts, and using pattern-matching expressions. The following sections provide an overview of some features of the shell command line relating to writing scripts.

---

**GROKKING GREP**

If you plan to develop shell scripts to expand the capabilities of pattern-matching commands such as grep, you will benefit from learning more about using expressions. One of the definitive guides to using the pattern-matching capabilities of UNIX and Linux commands is *Mastering Regular Expressions* by Jeffrey E. F. Freidl (O’Reilly), ISBN: 0-596-52812-4.
Shell Pattern-Matching Support

The shell command line allows you to use strings of specially constructed character patterns for wildcard matches. This is a different simpler capability than that supported by GNU utilities such as grep, which can use more complex patterns, known as expressions, to search through files or directories or to filter data input to or out of commands.

The shell’s pattern strings can be simple or complex, but even using a small subset of the available characters in simple wildcards can yield constructive results at the command line. Some common characters used for shell pattern matching are:

- `*`—Matches any character. For example, to find all files in the current directory ending in .txt, you could use
  ```bash
  matthew@seymour:~$ ls *.txt
  ```

- `?`—Matches a single character. For example, to find all files in the current directory ending in the extension .d?c (where ? could be 0–9, a–z, or A–Z), you could use
  ```bash
  matthew@seymour:~$ ls *.d?c
  ```

- `[xxx]` or `[x-x]`—Matches a range of characters. For example, to list all files in a directory with names containing numbers, you could use
  ```bash
  matthew@seymour:~$ ls *[0-9]*
  ```

- `\x`—Matches or escapes a character such as ? or a tab character. For example, to create a file with a name containing question mark, you could use
  ```bash
  matthew~$ touch foo\?
  ```

Note that the shell might not interpret some characters or regular expressions in the same manner as a Linux command, and mixing wildcards and regular expressions in shell scripts can lead to problems unless you’re careful. For example, finding patterns in text is best left to regular expressions used with commands such as grep; simple wildcards should be used for filtering or matching filenames on the command line. And although both Linux command expressions and shell scripts can recognize the backslash as an escape character in patterns, the dollar sign ($) will have two wildly different meanings (single-character pattern matching in expressions and variable assignment in scripts).

**CAUTION**

Make sure you read your command carefully when using wildcards; an all-too-common error is to type something like rm -rf * .txt with a space between the * and the .txt. By the time you wonder why the command is taking so long, Bash will already have deleted most of your files. The problem is that it will treat the * and the .txt separately. * will match everything, so Bash will delete all your files.

Redirecting Input and Output

You can create, overwrite, and append data to files at the command line, using a process called *input* and *output redirection*. The shell recognizes several special characters for this process, such as >, <, or >>.
In this example, the output of the `ls` command is redirected to create a file named `textfiles.listing`:

```
matthew@seymour:~$ ls *.txt >textfiles.listing
```

Use output redirection with care because it is possible to overwrite existing files. For example, specifying a different directory but using the same output filename will overwrite the existing `textfiles.listing`:

```
matthew@seymour:~$ ls /usr/share/doc/mutt-1.4/*.txt >textfiles.listing
```

Fortunately, most shells are smart enough to recognize when you might do something foolish. Here, the bash shell warns that the command is attempting to redirect output to a directory:

```
matthew@seymour:~$ mkdir foo
matthew@seymour:~$ ls >foo
bash: foo: Is a directory
```

Output can be appended to a file without overwriting existing content by using the append operator, `>>`. In this example, the directory listing will be appended to the end of `textfiles.listing` instead of overwriting its contents:

```
matthew@seymour:~$ ls /usr/share/doc/mutt-1.4/*.txt >>textfiles.listing
```

You can use `input redirection` to feed data into a command by using the `<` like this:

```
matthew@seymour:~$ cat < textfiles.listing
```

You can use the shell `here` operator, `<<`, to specify the end of input on the shell command line:

```
matthew@seymour:~$ cat >simple_script <<DONE
> echo "this is a simple script"
> DONE
$ cat simple_script
```

In this example, the shell will feed the cat command you are typing (input) until the pattern `DONE` is recognized. The output file `simple_script` is then saved and its contents verified. This same technique can be used in scripts to create content based on the output of various commands and define an end-of-input or delimiter.

### Piping Data

Many Linux commands can be used in concert in a single, connected command line to transform data from one form to another. Stringing Linux commands together in this fashion is known as using or creating *pipes*. Pipes are created on the command line with the bar operator (`|`). For example, a pipe can be used to perform a complex task from a single command line like this:

```
matthew@seymour:~$ find /d2 -name '*.txt' -print | xargs cat | \ tr ' ' '\n' | sort | uniq >output.txt
```

This example takes the output of the find command to feed the cat command (via `xargs`) the name all text files under the `/d2` command. The content of all matching files is then fed through the `tr` command to change each space in the data stream into a carriage
return. The stream of words is then sorted, and identical adjacent lines are removed using the \texttt{uniq} command. The output, a raw list of words, is then saved in the file named \texttt{output.txt}.

\section*{Background Processing}

The shell allows you to start a command and then launch it into the background as a process by using an ampersand (\&) at the end of a command line. This technique is often used at the command line of an X terminal window to start a client and return to the command line. For example, to launch another terminal window using the \texttt{xterm} client,

\begin{verbatim}
matthew@seymour:~$ xterm &
[3] 1437
\end{verbatim}

The numbers echoed back show a number (3 in this example), which is a job number, or reference number for a shell process, and a Process ID number, or PID (1437 in this example). The \texttt{xterm} window session can be killed by using the shell's built-in \texttt{kill} command, along with the job number like this:

\begin{verbatim}
matthew@seymour:~$ kill %3
\end{verbatim}

Or the process can be killed by using the \texttt{kill} command, along with the PID, like so:

\begin{verbatim}
matthew@seymour:~$ kill 1437
\end{verbatim}

Background processing can be used in shell scripts to start commands that take a long time, such as backups:

\begin{verbatim}
matthew@seymour:~$ tar -czf /backup/home.tgz /home &
\end{verbatim}

\section*{Writing and Executing a Shell Script}

Why should you write and use shell scripts? Shell scripts can save you time and typing, especially if you routinely use the same command lines multiple times every day. Although you could also use the history function (press the Up or Down keys while using \texttt{bash} or use the \texttt{history} command), a shell script can add flexibility with command-line argument substitution and built-in help.

Although a shell script won’t execute faster than a program written in a computer language such as C, a shell program can be smaller in size than a compiled program. The shell program does not require any additional library support other than the shell or, if used, existing commands installed on your system. The process of creating and testing shell scripts is also generally simpler and faster than the development process for equivalent C language commands.
NOTE

Hundreds of commands included with Ubuntu are actually shell scripts, and many other good shell script examples are available over the Internet—a quick search will yield numerous links to online tutorials and scripting guides from fellow Linux users and developers. For example, the startx command, used to start an X Window session from the text console, is a shell script used every day by most users. To learn more about shell scripting with bash, see the Advanced Bash-Scripting Guide, listed in the “Reference” section at the end of this chapter. You’ll also find Sams Teach Yourself Shell Programming in 24 Hours a helpful guide to learning more about using the shell to build your own commands.

When you are learning to write and execute your first shell scripts, start with scripts for simple, but useful tasks. Begin with short examples, and then expand the scripts as you build on your experience and knowledge. Make liberal use of comments (lines preceded with a pound # sign) to document each section of your script. Include an author statement and overview of the script as additional help, along with a creation date or version number. Write shell scripts using a text editor such as vi because it does not automatically wrap lines of text. Line wrapping can break script syntax and cause problems. If you use the nano editor, include its -w flag to disable line wrap.

In this section, you learn how to write a simple shell script to set up a number of aliases (command synonyms) whenever you log on. Instead of typing all the aliases every time you log on, you can put them in a file by using a text editor, such as vi, and then execute the file. Normally these changes are saved in systemwide shell configuration files under the /etc directory to make the changes active for all users or in your .bashrc, .cshrc (if you use tcsh), or .bash_profile files in your home directory.

Here is what is contained in myenv, a sample shell script created for this purpose (for bash):

```bash
#!/bin/sh
alias ll='ls -l'
alias ldir='ls -aF'
alias copy='cp'
```

This simple script creates command aliases, or convenient shorthand forms of commands, for the ls and cp commands. The ll alias provides a long directory listing: The ldir alias is the ls command, but prints indicators (for directories or executable files) in listings. The copy alias is the same as the cp command. You can experiment and add your own options or create aliases of other commands with options you frequently use.

You can execute myenv in a variety of ways under Linux. As shown in this example, you can make myenv executable by using the chmod command and then execute it as you would any other native Linux command:

```
matthew@seymour:~$ chmod +x myenv
```
This line turns on the executable permission of myenv, which can be checked with the `ls` command and its `-l` option like this:

```
matthew@seymour:$ ls -l myenv
-rwxr-xr-x 1 matthew matthew 0 2010-07-08 18:19 myenv
```

### Running the New Shell Program

You can run your new shell program in several ways. Each method will produce the same results, which is a testament to the flexibility of using the shell with Linux. One way to run your shell program is to execute the file `myenv` from the command line as if it were a Linux command:

```
matthew@seymour:$ ./myenv
```

A second way to execute `myenv` under a particular shell, such as `pdksh`, is as follows:

```
matthew@seymour:$ pdksh myenv
```

This invokes a new `pdksh` shell and passes the filename `myenv` as a parameter to execute the file. A third way will require you to create a directory named `bin` in your home directory, and to then copy the new shell program into this directory. You can then run the program without the need to specify a specific location or to use a shell. You do this like so:

```
matthew@seymour:$ mkdir bin
matthew@seymour:$ mv myenv bin
matthew@seymour:$ myenv
```

This works because Ubuntu is set up by default to include the executable path `$HOME/bin` in your shell's environment. You can view this environment variable, named `PATH`, by piping the output of the `env` command through `fgrep` like so:

```
matthew@seymour:$ env | fgrep PATH
/usr/kerberos/bin:/usr/local/bin:/bin:/usr/bin:
/usr/X11R6/bin:/sbin:/home/matthew/bin
```

As you can see, the user (matthew in this example) can use the new `bin` directory to hold executable files. Another way to bring up an environment variable is to use the `echo` command along with the variable name (in this case, `$PATH`):

```
matthew@seymour:$ echo $PATH
/usr/kerberos/bin:/usr/local/bin:/usr/bin:/bin:/usr/X11R6/bin:/home/bball/bin
```

---

**CAUTION**

Never put . in your `$PATH` to execute files or a command in the current directory—this presents a serious security risk, especially for the root operator, and even more so if . is first in your `$PATH` search order. Trojan scripts placed by crackers in directories such as `/tmp` can be used for malicious purposes, and will be executed immediately if the current working directory is part of your `$PATH`.

---

Storing Shell Scripts for Systemwide Access

After you execute the command `myenv`, you should be able to use `ldir` from the command line to get a list of files under the current directory and `ll` to get a list of files with attributes displayed. However, the best way to use the new commands in `myenv` is to put them into your shell’s login or profile file. For Ubuntu, and nearly all Linux users, the default shell is `bash`, so you can make these commands available for everyone on your system by putting them in the `/etc/bashrc` file. Systemwide aliases for `tcsh` are contained in files with the extension `.csh` under the `/etc/profile.d` directory. The `pdksh` shell can use these command aliases as well.

NOTE

To use a shell other than `bash` after logging in, use the `chsh` command from the command line or the `system-config-users` client during an X session. You’ll be asked for your password (or the root password if using `system-config-users`), as well as the location and name of the new shell (see Table 11.1). The new shell will become your default shell, but only if its name is in the list of acceptable system shells in `/etc/shells`.

Interpreting Shell Scripts Through Specific Shells

The majority of shell scripts use a shebang line (`#!/`) at the beginning to control the type of shell used to run the script; this bang line calls for an sh-incantation of `bash`:

```
#!/bin/sh
```

A shebang line (it is short for “sharp” and “bang”, two names for # and !) tells the Linux kernel that a specific command (a shell, or in the case of other scripts, perhaps awk or Perl) is to be used to interpret the contents of the file. Using a shebang line is common practice for all shell scripting. For example, if you write a shell script using `bash`, but want the script to execute as if run by the Bourne shell, `sh`, the first line of your script will contain `#!/bin/sh`, which is a link to the `bash` shell. Running `bash` as `sh` will cause `bash` to act as a Bourne shell. This is the reason for the symbolic link `sh`, which points to `bash`.

THE SHEBANG LINE

The shebang line is a magic number, as defined in `/usr/share/magic`—a text database of magic numbers for the Linux `file` command. Magic numbers are used by many different Linux commands to quickly identify a type of file, and the database format is documented in the section five manual page named `magic` (read by using `man 5 magic`). For example, magic numbers can be used by the Linux `file` command to display the identity of a script (no matter what filename is used) as a shell script using a specific shell or other interpreter such as awk or Perl.
You might also find different or new environment variables available to your scripts by using different shells. For example, if you launch csh from the bash command line, you will find several new variables or variables with slightly different definitions, such as:

```
matthew@seymour:~$ env
...
VENDOR=intel
MACHTYPE=i386
HOSTTYPE=i386-linux
HOST=thinkpad.home.org
```

On the other hand, bash might provide these variables or variables of the same name with a slightly different definition, such as:

```
$ env
...
HOSTTYPE=i386
HOSTNAME=thinkpad.home.org
```

Although the behavior of a shebang line is not defined by POSIX, variations of its use can be helpful when you are writing shell scripts. For example, as described in the wish man page, you can use a shell to help execute programs called within a shell script without needing to hard code pathnames of programs. The wish command is a windowing Tool Control Language (tcl) interpreter that can be used to write graphical clients. Avoiding the use of specific pathnames to programs increases shell script portability because not every UNIX or Linux system has programs in the same location.

For example, if you want to use the wish command, your first inclination might be to write

```
#!/usr/local/bin/wish
```

Although this will work on many other operating systems, the script will fail under Linux because wish is located under the /usr/bin directory. However, if you write the command line this way,

```
#!/bin/sh
exec wish "$@
```

you can use the wish command (as a binary or a shell script itself); your first inclination might be to write in Linux.

**Using Variables in Shell Scripts**

When writing shell scripts for Linux, you work with three types of variables:

- **Environment variables**—Part of the system environment, you can use them in your shell program. New variables can be defined, and some of them, such as PATH, can also be modified within a shell program.

- **Built-in variables**—Variables such as options used on the command (interpreted by the shell as a *positional argument*) are provided by Linux. Unlike environment variables, you cannot modify them.
User variables—Variables defined within a script when you write a shell script. You can use and modify them at will within the shell script but are not available to be used outside of the script.

A major difference between shell programming and other programming languages is that in shell programming, variables are not typed—that is, you do not have to specify whether a variable is a number or a string, and so on.

Assigning a Value to a Variable

Say that you want to use a variable called lcount to count the number of iterations in a loop within a shell program. You can declare and initialize this variable as follows:

<table>
<thead>
<tr>
<th>Command</th>
<th>Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>lcount=0</td>
<td>pdksh and bash</td>
</tr>
<tr>
<td>set lcount=0</td>
<td>tcsh</td>
</tr>
</tbody>
</table>

NOTE

Under pdksh and bash, you must ensure that the equal sign (=) does not have spaces before and after it.

To store a string in a variable, you can use the following:

<table>
<thead>
<tr>
<th>Command</th>
<th>Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>myname=Sanjiv</td>
<td>pdksh and bash</td>
</tr>
<tr>
<td>set myname=Sanjiv</td>
<td>tcsh</td>
</tr>
</tbody>
</table>

Use the preceding variable form if the string doesn’t have embedded spaces. If a string has embedded spaces, you can do the assignment as follows:

<table>
<thead>
<tr>
<th>Command</th>
<th>Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>myname=&quot;Sanjiv Guha&quot;</td>
<td>pdksh and bash</td>
</tr>
<tr>
<td>set myname=&quot;Sanjiv Guha&quot;</td>
<td>tcsh</td>
</tr>
</tbody>
</table>
Accessing Variable Values

You can access the value of a variable by prefixing the variable name with a $ (dollar sign). That is, if the variable name is `var`, you can access the variable by using `$var`.

If you want to assign the value of `var` to the variable `lcount`, you can do so as follows:

<table>
<thead>
<tr>
<th>Command</th>
<th>Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>lcount=$var</code></td>
<td>pdksh and bash</td>
</tr>
<tr>
<td><code>set</code></td>
<td>tcsh</td>
</tr>
<tr>
<td><code>lcount=$var</code></td>
<td></td>
</tr>
</tbody>
</table>

**Positional Parameters**

It is possible to pass options from the command line or from another shell script to your shell program.

These options are supplied to the shell program by Linux as *positional parameters*, which have special names provided by the system. The first parameter is stored in a variable called `1` (number 1) and can be accessed by using `$1` within the program. The second parameter is stored in a variable called `2` and can be accessed by using `$2` within the program, and so on. One or more of the higher numbered positional parameters can be omitted while you’re invoking a shell program.

Understanding how to use these positional parameters and how to access and use variables retrieved from the command line is necessary when developing more advanced shell programs.

**A Simple Example of a Positional Parameter**

For example, if a shell program `mygm` expects two parameters—such as a first name and a last name—you can invoke the shell program with only one parameter, the first name. However, you cannot invoke it with only the second parameter, the last name.

Here is a shell program called `mygm1`, which takes only one parameter (a name) and displays it on the screen:

```bash
#!/bin/sh
# Name display program
if [ $# -eq 0 ]
then
  echo "Name not provided"
else
  echo "Your name is "$1
fi
```
If you execute `mypgm1`, as follows,

```
$ bash mypgm1
```

you get the following output:

Name not provided

However, if you execute `mypgm1`, as follows,

```
$ bash mypgm1 Sanjiv
```

you get the following output:

Your name is Sanjiv

The shell program `mypgm1` also illustrates another aspect of shell programming: the built-in variables provided to the shell by the Linux kernel. In `mypgm1`, the built-in variable `$#` provides the number of positional parameters passed to the shell program. You learn more about working with built-in variables in the next major section of this chapter.

### Using Positional Parameters to Access and Retrieve Variables from the Command Line

Using positional parameters in scripts can be helpful if you need to use command lines with piped commands requiring complex arguments. Shell programs containing positional parameters can be even more convenient if the commands are infrequently used. For example, if you use your Ubuntu system with an attached voice modem as an answering machine, you can write a script to issue a command that retrieves and plays the voice messages. The following lines convert a saved sound file (in `.rmd` or voice-phone format) and pipe the result to your system’s audio device:

```
#!/bin/sh
# play voice message in /var/spool/voice/incoming
rmdtopvf /var/spool/voice/incoming/$1 | pvfspeed -s 8000 | \ pvftobasic > /dev/audio
```

A voice message can then easily be played back using this script (perhaps named `pmm`):

```
$pmm name_of_message
```

Shell scripts that contain positional parameters are often used for automating routine and mundane jobs, such as system log report generation, file system checks, user resource accounting, printer use accounting, and other system, network, or security administration tasks.
Using a Simple Script to Automate Tasks

You could use a simple script, for example, to examine your system log for certain keywords. If the script is run via your system’s scheduling table, /etc/crontab, it can help automate security monitoring. By combining the output capabilities of existing Linux commands with the language facilities of the shell, you can quickly build a useful script to perform a task normally requiring a number of command lines. For example, you can create a short script, named greplog, like this:

```
#!/bin/sh
#    name:  greplog
#      use:  mail grep of designated log using keyword
# version:  v.01 08aug02
#
#  author: bb
#
# usage: greplog [keyword] [logpathname]
#
#  bugs: does not check for correct number of arguments

# build report name using keyword search and date
log_report=/tmp/$1.logreport.`date '+%m%d%y'`

# build report header with system type, hostname, date and time
echo "=====================================================
     $log_report" >>$log_report
echo "           S Y S T E M   M O N I T O R   L O G" >>$log_report
echo uname -a >>$log_report
echo "Log report for" `hostname -f` "on" `date '+%c'" >>$log_report
echo "=====================================================" >>$log_report ; echo "" >>$log_report

# record log search start
echo "Search for->" $1 "starting" `date '+%r'" >>$log_report
echo "" >>$log_report

# get and save grep results of keyword ($1) from logfile ($2)
grep -i $1 $2 >>$log_report

# build report footer with time
echo "" >>$log_report
echo "End of" $log_report at `date '+%r'" >>$log_report

# mail report to root
mail -s "Log Analysis for $1" root <$log_report
```

In this example, the script creates the variable `$log_report`, which will be the filename of the temporary report. The keyword `($1)` and first argument on the command line is used as part of the filename, along with the current date (with perhaps a better approach to use `$$` instead of the date, which will append the script’s PID as a file extension). Next, the report header containing some formatted text, the output of the `uname` command, and the hostname and date is added to the report. The start of the search is then recorded, and any matches of the keyword in the log are added to the report. A footer containing the name of the report and the time is then added. The report is mailed to root with the search term as the subject of the message, and the temporary file is deleted.

You can test the script by running it manually and feeding it a keyword and a pathname to the system log, `/var/log/messages`, like this:

```
# greplog FAILED /var/log/messages
```

Note that your system should be running the `syslogd` daemon. If any login failures have occurred on your system, the root operator might get an email message that looks like this:

```
Date: Thu, 23 Oct 2003 16:23:24 -0400
From: root <root@stinkpad.home.org>
To: root@stinkpad.home.org
Subject: FAILED

==============================================================
S Y S T E M   M O N I T O R   L O G
Linux stinky 2.4.22-1.2088.nptl #1 Thu Oct 9 20:21:24 EDT 2003 i686 i686 i386 +GNU/Linux
Log report for stinkpad.home.org on Thu 23 Oct 2003 04:23:24 PM EDT
==============================================================

Oct 23 16:23:04 stinkpad login[1769]: FAILED LOGIN 3 FROM (null) FOR bball,
+Authentication failure

End of /tmp/FAILED.logreport.102303 at 04:23:24 PM

To further automate the process, you can include command lines using the script in another script to generate a series of searches and reports.
Built-In Variables

Built-in variables are special variables provided to shell by Linux that can be used to make decisions within a shell program. You cannot modify the values of these variables within the shell program.

Some of these variables are:

- `$#`—Number of positional parameters passed to the shell program
- `$?`—Completion code of the last command or shell program executed within the shell program (returned value)
- `$0`—The name of the shell program
- `$*`—A single string of all arguments passed at the time of invocation of the shell program

To show these built-in variables in use, here is a sample program called `mypgm2`:

```
#!/bin/sh
#my test program
echo "Number of parameters is $#"
echo "Program name is $0"
echo "Parameters as a single string is $*"
```

If you execute `mypgm2` from the command line in `pdksh` and `bash` as follows,

```
$ bash mypgm2 Sanjiv Guha
```

you get the following result:

```
Number of parameters is 2
Program name is mypgm2
Parameters as a single string is Sanjiv Guha
```

Special Characters

Some characters have special meaning to Linux shells; these characters represent commands, denote specific use for surrounding text, or provide search parameters. Special characters provide a sort of shorthand by incorporating these rather complex meanings into a simple character. Some special characters are shown in Table 11.2.
Special characters are very useful to you when you’re creating shell scripts, but if you inadvertently use a special character as part of variable names or strings, your program will behave incorrectly. As you learn in later parts of this section, you can use one of the special characters in a string if you precede it with an escape character (\, or backslash) to indicate that it isn’t being used as a special character and shouldn’t be treated as such by the program.

A few special characters deserve special note. They are the double quotes ("), the single quotes (‘), the backslash (\), and the backtick (‘)—all discussed in the following sections.

### Using Double Quotes to Resolve Variables in Strings with Embedded Spaces

If a string contains embedded spaces, you can enclose the string in double quotes (") so that the shell interprets the whole string as one entity instead of more than one.

### TABLE 11.2 Special Shell Characters

<table>
<thead>
<tr>
<th>Character</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>$</td>
<td>Indicates the beginning of a shell variable name</td>
</tr>
<tr>
<td>;</td>
<td>Pipes standard output to next command</td>
</tr>
<tr>
<td>#</td>
<td>Starts a comment</td>
</tr>
<tr>
<td>&amp;</td>
<td>Executes a process in the background</td>
</tr>
<tr>
<td>?</td>
<td>Matches one character</td>
</tr>
<tr>
<td>*</td>
<td>Matches one or more characters</td>
</tr>
<tr>
<td>&gt;</td>
<td>Output redirection operator</td>
</tr>
<tr>
<td>&lt;</td>
<td>Input redirection operator</td>
</tr>
<tr>
<td>`</td>
<td>Command substitution (the backquote or backtick—the key above the Tab key on most keyboards)</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>Output redirection operator (to append to a file)</td>
</tr>
<tr>
<td>&lt;&lt;</td>
<td>Wait until following end-of-input string (HERE operator)</td>
</tr>
<tr>
<td>[ ]</td>
<td>Range of characters</td>
</tr>
<tr>
<td>[a-z]</td>
<td>All characters a through z</td>
</tr>
<tr>
<td>[a,z] or [az]</td>
<td>Characters a or z</td>
</tr>
<tr>
<td>Space</td>
<td>Delimiter between two words</td>
</tr>
</tbody>
</table>
For example, if you assigned the value of `abc def` (abc followed by one space, followed by def) to a variable called `x` in a shell program as follows, you would get an error because the shell would try to execute `def` as a separate command:

<table>
<thead>
<tr>
<th>Command</th>
<th>Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x=&quot;abc def&quot;</code></td>
<td>pdksh and bash</td>
</tr>
<tr>
<td><code>set x = &quot;adb def&quot;</code></td>
<td>tcsh</td>
</tr>
</tbody>
</table>

The shell will execute the string as a single command if you surround the string in double quotes as follows:

<table>
<thead>
<tr>
<th>Command</th>
<th>Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x=abc def</code></td>
<td>pdksh and bash</td>
</tr>
<tr>
<td><code>set x=abc def</code></td>
<td>tcsh</td>
</tr>
</tbody>
</table>

The double quotes resolve all variables within the string. Here is an example for `pdksh` and `bash`:

```bash
var="test string"
newvar="Value of var is $var"
echo $newvar
```

Here is the same example for `tcsh`:

```bash
set var="test string"
set newvar="Value of var is $var"
echo $newvar
```

If you execute a shell program containing the preceding three lines, you get the following result:

```
Value of var is test string
```

### Using Single Quotes to Maintain Unexpanded Variables

You can surround a string with single quotes (') to stop the shell from expanding variables and interpreting special characters. When used for the latter purpose, the single quote is an escape character, similar to the backslash, which you learn about in the next section. Here, you learn how to use the single quote to avoid expanding a variable in a shell script. An unexpanded variable maintains its original form in the output.

In the following examples, the double quotes in the preceding examples have been changed to single quotes.
pdksh and bash:
var='test string'
newvar='Value of var is $var'
echo $newvar
tcsh:
set var = 'test string'
set newvar = 'Value of var is $var'
echo $newvar

If you execute a shell program containing these three lines, you get the following result:
Value of var is $var

As you can see, the variable var maintains its original format in the results, rather than having been expanded.

Using the Backslash as an Escape Character

As you learned earlier, the backslash (\) serves as an escape character that stops the shell from interpreting the succeeding character as a special character. Say that you want to assign a value of $test to a variable called var. If you use the following command, the shell reads the special character $ and interprets $test as the value of the variable test. No value has been assigned to test; a null value is stored in var as follows:

<table>
<thead>
<tr>
<th>Command</th>
<th>Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>var=$test</td>
<td>pdksh and bash</td>
</tr>
<tr>
<td>set</td>
<td>tcsh</td>
</tr>
<tr>
<td>var=$test</td>
<td></td>
</tr>
</tbody>
</table>

Unfortunately, this assignment may work for bash and pdksh, but it returns an error of “undefined variable” if you use it with tcsh. Use the following commands to correctly store $test in var:

<table>
<thead>
<tr>
<th>Command</th>
<th>Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>var=<code>wc -l test.txt</code></td>
<td>pdksh and bash</td>
</tr>
<tr>
<td>set var = <code>wc -l test.txt</code></td>
<td>tcsh</td>
</tr>
</tbody>
</table>

The backslash before the dollar sign (\$) signals the shell to interpret the $ as any other ordinary character and not to associate any special meaning to it. You could also use single quotes (’) around the $test variable to get the same result.

Using the Backtick to Replace a String with Output

You can use the backtick (‘) character to signal the shell to replace a string with its output when executed. This is called command substitution. This special character can be used in
shell programs when you want the result of the execution of a command to be stored in a variable. For example, if you want to count the number of lines in a file called test.txt in the current directory and store the result in a variable called var, you can use the following command:

```
Command    Environment
var=$test   pdksh and bash
set var = \\
\$test     tcsh
```

**Comparison of Expressions in pdksh and bash**

Comparing values or evaluating the differences between similar bits of data—such as file information, character strings, or numbers—is a task known as *comparison of expressions*. Comparison of expressions is an integral part of using logic in shell programs to accomplish tasks. The way the logical comparison of two operators (numeric or string) is done varies slightly in different shells. In pdksh and bash, a command called `test` can be used to achieve comparisons of expressions. In tcsh, you can write an expression to accomplish the same thing.

This section covers comparison operations using the pdksh or bash shells. Later in the chapter, you learn how to compare expressions in the tcsh shell.

The pdksh and bash shell syntax provide a command named `test` to compare strings, numbers, and files. The syntax of the `test` command is as follows:

```
test expression
or
[ expression ]
```

Both forms of the `test` commands are processed the same way by pdksh and bash. The `test` commands support the following types of comparisons:

- String comparison
- Numeric comparison
- File operators
- Logical operators

**String Comparison**

The following operators can be used to compare two string expressions:

- `=`—To compare whether two strings are equal
- `!=`—To compare whether two strings are not equal
- `-n`—To evaluate whether the string length is greater than zero
- `-z`—To evaluate whether the string length is equal to zero
Next are some examples using these operators when comparing two strings, string1 and string2, in a shell program called compare1:

```bash
#!/bin/sh
string1="abc"
string2="abd"
if [ $string1 = $string2 ]; then
    echo "string1 equal to string2"
else
    echo "string1 not equal to string2"
fi

if [ $string2 != string1 ]; then
    echo "string2 not equal to string1"
else
    echo "string2 equal to string2"
fi

if [ $string1 ]; then
    echo "string1 is not empty"
else
    echo "string1 is empty"
fi

if [ -n $string2 ]; then
    echo "string2 has a length greater than zero"
else
    echo "string2 has length equal to zero"
fi

if [ -z $string1 ]; then
    echo "string1 has a length equal to zero"
else
    echo "string1 has a length greater than zero"
fi

If you execute compare1, you get the following result:

string1 not equal to string2
string2 not equal to string1
string1 is not empty
string2 has a length greater than zero
string1 has a length greater than zero

If two strings are not equal in size, the system pads out the shorter string with trailing spaces for comparison. That is, if the value of string1 is abc and that of string2 is ab,
string2 will be padded with a trailing space for comparison purposes—it will have a value of ab.

**Number Comparison**  The following operators can be used to compare two numbers:

- `eq`—To compare whether two numbers are equal
- `ge`—To compare whether one number is greater than or equal to the other number
- `le`—To compare whether one number is less than or equal to the other number
- `ne`—To compare whether two numbers are not equal
- `gt`—To compare whether one number is greater than the other number
- `lt`—To compare whether one number is less than the other number

The following shell program compares three numbers, `number1`, `number2`, and `number3`:

```bash
#!/bin/sh
number1=5
number2=10
number3=5

if [ $number1 -eq $number3 ]; then
    echo "number1 is equal to number3"
else
    echo "number1 is not equal to number3"
fi

if [ $number1 -ne $number2 ]; then
    echo "number1 is not equal to number2"
else
    echo "number1 is equal to number2"
fi

if [ $number1 -gt $number2 ]; then
    echo "number1 is greater than number2"
else
    echo "number1 is not greater than number2"
fi

if [ $number1 -ge $number3 ]; then
    echo "number1 is greater than or equal to number3"
else
    echo "number1 is not greater than or equal to number3"
fi

if [ $number1 -lt $number2 ]; then
    echo "number1 is less than number2"
else
    echo "number1 is not less than number2"
fi
```
echo "number1 is less than number2"
else
  echo "number1 is not less than number2"
fi

if [ $number1 -le $number3 ]; then
  echo "number1 is less than or equal to number3"
else
  echo "number1 is not less than or equal to number3"
fi

When you execute the shell program, you get the following results:

number1 is equal to number3  
number1 is not equal to number2  
number1 is not greater than number2  
number1 is greater than or equal to number3  
number1 is less than number2  
number1 is less than or equal to number3

File Operators

The following operators can be used as file comparison operators:

- -d—To ascertain whether a file is a directory
- -f—To ascertain whether a file is a regular file
- -r—To ascertain whether read permission is set for a file
- -s—To ascertain whether a file exists and has a length greater than zero
- -w—To ascertain whether write permission is set for a file
- -x—To ascertain whether execute permission is set for a file

Assume that a shell program called compare3 is in a directory with a file called file1 and a subdirectory dir1 under the current directory. Assume that file1 has a permission of r-x (read and execute permission) and dir1 has a permission of rwx (read, write, and execute permission). The code for the shell program would look like this:

#!/bin/sh
if [ -d $dir1 ]; then
  echo "dir1 is a directory"
else
  echo "dir1 is not a directory"
fi

if [ -f $dir1 ]; then
  echo "dir1 is a regular file"
else
echo "dir1 is not a regular file"
fi

if [ -r $file1 ]; then
    echo "file1 has read permission"
else
    echo "file1 does not have read permission"
fi

if [ -w $file1 ]; then
    echo "file1 has write permission"
else
    echo "file1 does not have write permission"
fi

if [ -x $dir1 ]; then
    echo "dir1 has execute permission"
else
    echo "dir1 does not have execute permission"
fi

If you execute the shell program, you get the following results:

dir1 is a directory
file1 is a regular file
file1 has read permission
file1 does not have write permission
dir1 has execute permission

Logical Operators
Logical operators are used to compare expressions using Boolean logic, which compares values using characters representing \texttt{NOT}, \texttt{AND}, and \texttt{OR}.

\begin{itemize}
\item \texttt{!}—To negate a logical expression
\item \texttt{-a}—To logically \texttt{AND} two logical expressions
\item \texttt{-o}—To logically \texttt{OR} two logical expressions
\end{itemize}

This example named \texttt{logic} uses the file and directory mentioned in the previous \texttt{compare3} example.

```
#!/bin/sh
if [ -x $file1 -a -x $dir1 ]; then
    echo "file1 and dir1 are executable"
else
    echo "at least one of file1 or dir1 are not executable"
fi
```
if [ -w file1 -o -w dir1 ]; then  
  echo file1 or dir1 are writable
else  
  echo neither file1 or dir1 are executable
fi

if [ ! -w file1 ]; then  
  echo file1 is not writable
else  
  echo file1 is writable
fi
If you execute logic, it will yield the following result:  
file1 and dir1 are executable  
file1 or dir1 are writable  
file1 is not writable

Comparing Expressions with tcsh

As stated earlier, the method for comparing expressions in tcsh is different from the  
method used under pdksh and bash. The comparison of expression demonstrated in this  
section uses the syntax necessary for the tcsh shell environment.

String Comparison

The following operators can be used to compare two string expressions:

  ➤  ==—To compare whether two strings are equal
  ➤  !=—To compare whether two strings are not equal

The following examples compare two strings, string1 and string2, in the shell program  
compare1:

#!/bin/tcsh  
set string1 = "abc"  
set string2 = "abd"

if (string1 == string2) then  
  echo "string1 equal to string2"
else  
  echo "string1 not equal to string2"
endif

if (string2 != string1) then  
  echo "string2 not equal to string1"
else  
  echo "string2 equal to string1"
endif
If you execute `compare1`, you get the following results:

string1 not equal to string2
string2 not equal to string1

**Number Comparison**

These operators can be used to compare two numbers:

- `>=`—To compare whether one number is greater than or equal to the other number
- `<=`—To compare whether one number is less than or equal to the other number
- `>`—To compare whether one number is greater than the other number
- `<`—To compare whether one number is less than the other number

The next examples compare two numbers, `number1` and `number2`, in a shell program called `compare2`:

```bash
#!/bin/tcsh
set number1=5
set number2=10
set number3=5

if  ($number1 > $number2)  then
   echo "number1 is greater than number2"
else
   echo "number1 is not greater than number2"
endif

if  ($number1 >= $number3) then
   echo "number1 is greater than or equal to number3"
else
   echo "number1 is not greater than or equal to number3"
endif

if  ($number1 < $number2)  then
   echo "number1 is less than number2"
else
   echo "number1 is not less than number2"
endif

if  ($number1 <= $number3) then
   echo "number1 is less than or equal to number3"
else
   echo "number1 is not less than or equal to number3"
endif
```
When executing the shell program `compare2`, you get the following results:

- `number1` is not greater than `number2`
- `number1` is greater than or equal to `number3`
- `number1` is less than `number2`
- `number1` is less than or equal to `number3`

### File Operators

These operators can be used as file comparison operators:

- `-d`—To ascertain whether a file is a directory
- `-e`—To ascertain whether a file exists
- `-f`—To ascertain whether a file is a regular file
- `-o`—To ascertain whether a user is the owner of a file
- `-r`—To ascertain whether read permission is set for a file
- `-w`—To ascertain whether write permission is set for a file
- `-x`—To ascertain whether execute permission is set for a file
- `-z`—To ascertain whether the file size is zero

The following examples are based on a shell program called `compare3`, which is in a directory with a file called `file1` and a subdirectory `dir1` under the current directory. Assume that `file1` has a permission of `r-x` (read and execute permission) and `dir1` has a permission of `rwx` (read, write, and execute permission).

The following is the code for the `compare3` shell program:

```bash
#!/bin/tcsh
if (-d dir1) then
    echo "dir1 is a directory"
else
    echo "dir1 is not a directory"
endif

if (-f dir1) then
    echo "file1 is a regular file"
else
    echo "file1 is not a regular file"
endif

if (-r file1) then
    echo "file1 has read permission"
else
    echo "file1 does not have read permission"
endif
```
endif

if (-w file1) then
    echo "file1 has write permission"
else
    echo "file1 does not have write permission"
endif

if (-x dir1) then
    echo "dir1 has execute permission"
else
    echo "dir1 does not have execute permission"
endif

if (-z file1) then
    echo "file1 has zero length"
else
    echo "file1 has greater than zero length"
endif

If you execute the file compare3, you get the following results:

dir1 is a directory
file1 is a regular file
file1 has read permission
file1 does not have write permission
dir1 has execute permission
file1 has greater than zero length

Logical Operators
Logical operators are used with conditional statements. These operators are used to negate a logical expression or to perform logical ANDs and ORs:

- !—To negate a logical expression
- &&—To logically AND two logical expressions
- ||—To logically OR two logical expressions

This example named logic uses the file and directory mentioned in the previous compare3 example.

#!/bin/tcsh
if ( -x file1 && -x dir1 ) then
    echo file1 and dir1 are executable
else
    echo at least one of file1 or dir1 are not executable
endif
if ( -w file1 || -w dir1 ) then
    echo file1 or dir1 are writable
else
    echo neither file1 or dir1 are executable
endif

if ( ! -w file1 ) then
    echo file1 is not writable
else
    echo file1 is writable
endif

If you execute logic, it will yield the following result:

file1 and dir1 are executable
file1 or dir1 are writable
file1 is not writable

The for Statement

The for statement is used to execute a set of commands once each time a specified condition is true. The for statement has a number of formats. The first format used by pdksh and bash is as follows:

for curvar in list
do
    statements
done

This form should be used if you want to execute statements once for each value in list. For each iteration, the current value of the list is assigned to vcurvar. list can be a variable containing a number of items or a list of values separated by spaces. The second format is as follows:

for curvar
do
    statements
done

In this form, the statements are executed once for each of the positional parameters passed to the shell program. For each iteration, the current value of the positional parameter is assigned to the variable curvar.

This form can also be written as follows:

for curvar in $
do
    statements
done
Remember that $@ gives you a list of positional parameters passed to the shell program, quoted in a manner consistent with the way the user originally invoked the command.

Under tcsh, the for statement is called foreach. The format is as follows:

```
foreach curvar (list)
  statements
end
```

In this form, statements are executed once for each value in list, and, for each iteration, the current value of list is assigned to curvar.

Suppose that you want to create a backup version of each file in a directory to a subdirectory called backup. You can do the following in pdksh and bash:

```
#!/bin/sh
for filename in *
do
  cp $filename backup/$filename
  if [ $? -ne 0 ]; then
    echo "copy for $filename failed"
  fi
done
In the preceding example, a backup copy of each file is created. If the copy fails, a message is generated.

The same example in tcsh is as follows:

```
#!/bin/tcsh
foreach filename (`/bin/ls`) 
  cp $filename backup/$filename
  if ($? != 0) then
    echo "copy for $filename failed"
  endif
end
```

### The while Statement

The while statement can be used to execute a series of commands while a specified condition is true. The loop terminates as soon as the specified condition evaluates to false. It is possible that the loop will not execute at all if the specified condition initially evaluates to false. You should be careful with the while command because the loop will never terminate if the specified condition never evaluates to false.
Endless loops can sometimes be useful. For example, you can easily construct a simple command that constantly monitors the 802.11b link quality of a network interface by using a few lines of script:

```
#!/bin/sh
while :
do
  /sbin/iwconfig eth0 | grep Link | tr '
' ''
done
```

The script outputs the search, and then the `tr` command formats the output. The result is a simple animation of a constantly updated single line of information:

```
Link Quality:92/92 Signal level:-11 dBm Noise level:-102 dBm
```

This technique can also be used to create a graphical monitoring client for X that outputs traffic information and activity about a network interface:

```
#!/bin/sh
xterm -geometry 75x2 -e 
bash -c 
"while ;; do 
  /sbin/ifconfig eth0 | 
  grep 'TX bytes' | 
  tr '
' '' ; 
  done"
```

The simple example uses a bash command-line script (enabled by `-c`) to execute a command line repeatedly. The command line pipes the output of the `ifconfig` command through `grep`, which searches `ifconfig`'s output and then pipes a line containing the string "TX bytes" to the `tr` command. The `tr` command then removes the carriage return at the end of the line to display the information inside an `/xterm` X11 terminal window, automatically sized by the `-geometry` option:

```
RX bytes:4117594780 (3926.8 Mb)  TX bytes:452230967 (431.2 Mb)
```

Endless loops can be so useful that Linux includes a command that will repeatedly execute a given command line. For example, you can get a quick report about a system's hardware health by using the `sensors` command. But instead of using a shell script to loop the output endlessly, you can use the `watch` command to repeat the information and provide simple animation:

```
$ watch "sensors -f | cut -c 1-20"
```
In pdksh and bash, the following format is used for the while flow control construct:

```bash
while expression
do
  statements
done
```

In tcsh, the following format is used:
```
while (expression)
  Statements
end
```

If you want to add the first five even numbers, you can use the following shell program in pdksh and bash:

```bash
#!/bin/bash
loopcount=0
result=0
while [ $loopcount -lt 5 ]
do
  loopcount=`expr $loopcount + 1`
  increment=`expr $loopcount \* 2`
  result=`expr $result + $increment`
done

echo "result is $result"
```

In tcsh, this program can be written as follows:

```bash
#!/bin/tcsh
set loopcount = 0
set result = 0
while ($loopcount < 5)
do
  set loopcount = `expr $loopcount + 1`
  set increment = `expr $loopcount \* 2`
  set result = `expr $result + $increment`
done

echo "result is $result"
```

**The until Statement**

The until statement can be used to execute a series of commands until a specified condition is true.

The loop terminates as soon as the specified condition evaluates to True.
In pdksh and bash, the following format is used:

```
until expression
do
    statements
done
```

As you can see, the format of the `until` statement is similar to that of the `while` statement, but the logic is different: In a `while` loop, you execute until an expression is `False`, but in an `until` loop, you loop until the expression is `True`.

If you want to add the first five even numbers, you can use the following shell program in pdksh and bash:

```bash
#!/bin/bash
loopcount=0
result=0
until [ $loopcount -ge 5 ]
do
    loopcount=`expr $loopcount + 1`
    increment=`expr $loopcount \* 2`
    result=`expr $result + $increment`
done
echo "result is $result"
```

The example here is identical to the example for the `while` statement, except that the condition being tested is just the opposite of the condition specified in the `while` statement.

The `tcsh` shell does not support the `until` statement.

**The repeat Statement (tcsh)**

The `repeat` statement is used to execute only one command a fixed number of times.

If you want to print a hyphen (-) 80 times with one hyphen per line on the screen, you can use the following command:

```
repeat 80 echo '-'
```

**The select Statement (pdksh)**

The `select` statement is used to generate a menu list if you are writing a shell program that expects input from the user online. The format of the `select` statement is as follows:

```
select  item in itemlist
do
    Statements
```

```bash
select  item in itemlist
do
    Statements
```

```bash
select  item in itemlist
do
    Statements
```
itemlist is optional. If it isn’t provided, the system iterates through the item entries one at a time. If itemlist is provided, however, the system iterates for each entry in itemlist and the current value of itemlist is assigned to item for each iteration, which then can be used as part of the statements being executed.

If you want to write a menu that gives the user a choice of picking a Continue or a Finish, you can write the following shell program:

```
#!/bin/ksh
select item in Continue Finish
do
    if [ $item = "Finish" ]; then
        break
    fi
done
```

When the `select` command is executed, the system displays a menu with numeric choices to the user—in this case, 1 for Continue and 2 for Finish. If the user chooses 1, the variable item contains a value of Continue; if the user chooses 2, the variable item contains a value of Finish. When the user chooses 2, the `if` statement is executed and the loop terminates.

**The shift Statement**

The shift statement is used to process the positional parameters, one at a time, from left to right. As you’ll remember, the positional parameters are identified as $1, $2, $3, and so on. The effect of the `shift` command is that each positional parameter is moved one position to the left and the current $1 parameter is lost.

The `shift` statement is useful when you are writing shell programs in which a user can pass various options. Depending on the specified option, the parameters that follow can mean different things or might not be there at all.

The format of the `shift` command is as follows:

```
shift number
```

The parameter number is the number of places to be shifted and is optional. If not specified, the default is 1; that is, the parameters are shifted one position to the left. If specified, the parameters are shifted number positions to the left.

**The if Statement**

The if statement evaluates a logical expression to make a decision. An if condition has the following format in pdksh and bash:

```
if [ expression ]; then
    Statements
```

elif [ expression ]; then
  Statements
else
  Statements
fi

The if conditions can be nested. That is, an if condition can contain another if condition within it. It isn’t necessary for an if condition to have an elif or else part. The else part is executed if none of the expressions that are specified in the if statement and are optional if subsequent elif statements are true. The word fi is used to indicate the end of the if statements, which is very useful if you have nested if conditions. In such a case, you should be able to match fi to if to ensure that all if statements are properly coded.

In the following example for bash or pdksh, a variable var can have either of two values: Yes or No. Any other value is invalid. This can be coded as follows:

```bash
if [ $var = "Yes" ]; then
  echo "Value is Yes"
elif [ $var = "No" ]; then
  echo "Value is No"
else
  echo "Invalid value"
fi
```

In tcsh, the if statement has two forms. The first form, similar to the one for pdksh and bash, is as follows:

```tcsh
if (expression) then
  Statements
else if (expression) then
  Statements
else
  Statements
endif
```

In tcsh, the if statement has two forms. The first form, similar to the one for pdksh and bash, is as follows:

The if conditions can be nested—that is, an if condition can contain another if condition within it. It isn’t necessary for an if condition to have an else part. The else part is executed if none of the expressions specified in any of the if statements are true. The optional if part of the statement (else if (expression) then) is executed if the condition following it is true and the previous if statement is not true. The word endif is used to indicate the end of the if statements, which is very useful if you have nested if conditions. In such a case, you should be able to match endif to if to ensure that all if statements are properly coded.

Using the example of the variable var having only two values, Yes and No, here is how it would be coded with tcsh:

```tcsh
if ($var == "Yes") then
  echo "Value is Yes"
else if ($var == "No") then
  echo "Value is No"
else
  echo "Invalid value"
endif
```
echo "Value is Yes"
else if ($var == "No" ) then
    echo "Value is No"
else
    echo "Invalid value"
endif

The second form of the if condition for tcsh is as follows:

if (expression) command

In this format, only a single command can be executed if the expression evaluates to true.

The case Statement

The case statement is used to execute statements depending on a discrete value or a range of values matching the specified variable. In most cases, you can use a case statement instead of an if statement if you have a large number of conditions.

The format of a case statement for pdksh and bash is as follows:

case str in
    str1 | str2)
        Statements;;
    str3 | str4)
        Statements;;
    *)
        Statements;;
esac

You can specify a number of discrete values—such as str1, str2, and so on—for each condition, or you can specify a value with a wildcard. The last condition should be * (asterisk) and is executed if none of the other conditions are met. For each of the specified conditions, all the associated statements until the double semicolon (;;) are executed.

You can write a script that will echo the name of the month if you provide the month number as a parameter. If you provide a number that isn’t between 1 and 12, you will get an error message. The script is as follows:

#!/bin/sh

case $1 in
    01 | 1) echo "Month is January";;
    02 | 2) echo "Month is February";;
    03 | 3) echo "Month is March";;
    04 | 4) echo "Month is April";;
    05 | 5) echo "Month is May";;
    06 | 6) echo "Month is June";;
case str1|str2:
    Statements
    breaksw
   
case str3|str4:
    Statements
    breaksw
   
default:
    Statements
    breaksw

endsw

You can specify a number of discrete values—such as str1, str2, and so on—for each condition, or you can specify a value with a wildcard. The last condition should be default and is executed if none of the other conditions are met. For each of the specified conditions, all the associated statements until breaksw are executed.

The example that echoes the month when a number is given, shown earlier for pdksh and bash, can be written in tcsh as follows:

```
#!/bin/tcsh

set month = 5
switch ( $month )
    case 1: echo "Month is January" ; breaksw
    case 2: echo "Month is February" ; breaksw
    case 3: echo "Month is March" ; breaksw
    case 4: echo "Month is April" ; breaksw
    case 5: echo "Month is May" ; breaksw
    case 6: echo "Month is June" ; breaksw
    case 7: echo "Month is July" ; breaksw
    case 8: echo "Month is August" ; breaksw
    case 9: echo "Month is September" ; breaksw
    case 10: echo "Month is October" ;
    case 11: echo "Month is November" ;
    case 12: echo "Month is December" ;
    *) echo "Invalid parameter" ;
esac
```

You need to end the statements under each condition with a double semicolon (;;). If you do not, the statements under the next condition will also be executed.
case 10: echo "Month is October" ; break
case 11: echo "Month is November" ; break
case 12: echo "Month is December" ; break
default: echo "Oops! Month is October!" ; break
end

You need to end the statements under each condition with break. If you do not, the statements under the next condition will also be executed.

**The break and exit Statements**

You should be aware of two other statements: the break statement and the exit statement.

The break statement can be used to terminate an iteration loop, such as a for, until, or repeat command.

exit statements can be used to exit a shell program. You can optionally use a number after exit. If the current shell program has been called by another shell program, the calling program can check for the code (the $? or $status variable, depending on shell) and make a decision accordingly.

**Using Functions in Shell Scripts**

As with other programming languages, shell programs also support functions. A function is a piece of a shell program that performs a particular process; you can reuse the same function multiple times within the shell program. Functions help eliminate the need for duplicating code as you write shell programs.

The following is the format of a function in pdksh and bash:

```
func(){
  Statements
}
```

You can call a function as follows:

`func param1 param2 param3`

The parameters `param1`, `param2`, and so on are optional. You can also pass the parameters as a single string—for example, `$@`. A function can parse the parameters as if they were positional parameters passed to a shell program from the command line as command-line arguments, but instead use values passed inside the script. For example, the following script uses a function named `Displaymonth()` that displays the name of the month or an error message if you pass a month number out of the range 1 to 12. This example works with pdksh and bash:

```
#!/bin/sh
Displaymonth() {
  case $1 in
    01 | 1) echo "Month is January";;
```
Displaymonth 8

The preceding program displays the following output:

Month is August

RELATED UBUNTU AND LINUX COMMANDS

You can use these commands and tools when using the shell or writing shell scripts:

- **chsh**—Command used to change one’s login shell
- **kibitz**—Allows two-person interaction with a single shell
- **mc**—A visual shell named the GNU Midnight Commander
- **nano**—An easy-to-use text editor for the console
- **shar**—Command used to create shell archives
- **vi**—The vi (actually vim) text editor

To keep your system in optimum shape, you need to be able to monitor it closely. This is imperative in a corporate environment where uptime is vital and any system failures and downtime can be quite expensive. Whether it is checking processes for errant daemons, or keeping a close eye on CPU and memory usage, Ubuntu provides a wealth of utilities designed to give you as little or as much feedback as you want. This chapter looks at some of the basic monitoring tools, along with some tactics designed to keep your system up longer. Some of the monitoring tools cover network connectivity, memory, and hard drive usage, and you will learn how to manipulate active system processes, using a mixture of graphical and command-line tools.

**Console-Based Monitoring**

Those familiar with UNIX system administration already know the `ps`, or process display, command commonly found on most flavors of UNIX. Because of the close relationship between Linux and UNIX, it also includes this command, which allows you to see the current processes running on the system, as well as who owns them and how resource-hungry they are.

Although the Linux kernel has its own distinct architecture and memory management, it also benefits from enhanced use of the `/proc` file system, the virtual file system found on many UNIX flavors. Through the `/proc` file system you can communicate directly with the kernel to get a deep view of what is currently happening. Developers tend to use the `/proc` file system as a way of extracting information from the kernel and for their programs to manipulate that infor-
information into more human readable formats. A full discussion of the /proc file system is beyond the scope of this book. To get a better idea of what it contains you can take a look at http://en.tldp.org/LDP/Linux-Filesystem-Hierarchy/html/proc.html for an excellent and in-depth guide.

Processes can also be controlled at the command line, which is important because you might sometimes have only a command-line interface. Whenever an application or command is launched, either from the command line or a clicked icon, the process that comes from the kernel is assigned an identification number called a process ID or PID for short. This number is shown in the shell if the program is launched via the command line.

```
matthew@seymour:~$ gedit &
```

[1] 9649

In this example, gedit has been launched in the background, and the (bash) shell reported a shell job number ([1] in this case). A job number or job control is a shell-specific feature that allows a different form of process control, such as sending or suspending programs to the background and retrieving background jobs to the foreground (see your shell's man pages for more information if you are not using bash).

The second number displayed (9649 in this example) represents the process ID. You can get a quick list of your processes by using the ps command like this:

```
matthew@seymour:~$ ps
  PID TTY          TIME CMD
  9595 pts/0    00:00:00 bash
  9656 pts/0    00:00:00 gedit
  9657 pts/0    00:00:00 ps
```

As you can see, the output includes the process ID, abbreviated as PID, along with other information, such as the name of the running program. As with any UNIX command, many options are available; the proc man page has a full list. One useful option is -e, which lists all processes running on the system. Another is aux, which provides a more detailed list of all the processes. You should also know that ps works not by polling memory, but through the interrogation of the Linux /proc or process file system.

The /proc directory contains many files—some of which include constantly updated hardware information (such as battery power levels, and so on). Linux administrators often pipe the output of ps through grep to display information about a specific program, like this:

```
matthew@seymour:~$ ps aux | grep bash
matthew      9656  0.0  0.1  21660  4460 pts/0    Ss   11:39   0:00 bash
```

This example returns the owner (the user who launched the program) and the PID, along with other information, such as the percentage of CPU and memory usage, size of the
command (code, data, and stack), time (or date) the command was launched, and name of the command. Processes can also be queried by PID like this:

```
matthew@seymour:~$ ps 9656
 PID TTY      STAT   TIME COMMAND
 9656 pts/0    S      0:00 gedit
```

You can use the PID to stop a running process by using the shell’s built-in `kill` command. This command asks the kernel to stop a running process and reclaim system memory. For example, to stop `gedit` in the example, use the `kill` command like this:

```
matthew@seymour:~$ kill 9656
```

After you press Enter, then press Enter again, the shell reports

```
[1]+ Terminated         gedit
```

Note that users can `kill` only their own processes, but `root` can kill them all. Controlling any other running process requires root permission, which should be used judiciously (especially when forcing a `kill` by using the `-9` option); by inadvertently killing the wrong process through a typo in the command, you could bring down an active system.

### Using the `kill` Command to Control Processes

The `kill` command is a basic UNIX system command. You can communicate with a running process by entering a command into its interface, such as when you type into a text editor. But some processes (usually system processes rather than application processes) run without such an interface, and you need a way to communicate with them as well, so we use a system of signals. The `kill` system accomplishes that by sending a signal to a process, and you can use it to communicate with any process. The general format of the `kill` command is

```
matthew@seymour:~$ kill option PID
```

Note that if you are using `kill` on a process you do not own, you need to have super-user privileges and preface the `kill` command with `sudo`.

A number of signal options can be sent as words or numbers, but most are of interest only to programmers. One of the most common is the one we used previously to kill `gedit`:

```
matthew@seymour:~$ kill PID
```

This tells the process with PID to stop; you supply the actual PID. However, without a signal option, there is no guarantee that a process will be killed, because programs can catch, block, or ignore some terminate signals (and this is a good thing, by design).

```
matthew@seymour:~$ kill -9 PID
```

This includes a signal for `kill` that cannot be caught (9 is the number of the SIGKILL signal); you can use this combination when the plain `kill` shown previously does not work. Be careful, though. Using this does not allow a process to shut down gracefully, and shutting down gracefully is usually preferred because it closes things out that the process may have been using and ensures that things such as logs are written before the process disappears.

```
matthew@seymour:~$ kill -1 PID
```
This is the signal to “hang up”—stop—and then clean up all associated processes as well (1 is the number of the `SIGHUP` signal).

As you become proficient at process control and job control, you will learn the utility of a number of `kill` options. A full list of signal options can be found in the `kill` man page.

**Using Priority Scheduling and Control**

No process can make use of the system’s resources (CPU, memory, disk access, and so on) as it pleases. After all, the kernel’s primary function is to manage the system resources equitably. It does this by assigning a priority to each process so that some processes get better access to system resources and some processes might have to wait longer until their turn arrives. Priority scheduling can be an important tool in managing a system supporting critical applications or in a situation in which CPU and RAM usage must be reserved or allocated for a specific task. Two useful applications included with Ubuntu include the `nice` and `renice` commands. (`nice` is part of the GNU `coreutils` package, whereas `renice` is inherited from BSD UNIX.)

The `nice` command is used with its `-n` option, along with an argument in the range of `-20` to `19`, in order from highest to lowest priority (the lower the number, the higher the priority). For example, to run the `conky` client with a low priority, use the `nice` command like this (more on conky later in this chapter):

```
matthew@seymour:~$ nice -n 12 conky &
```

The `nice` command is typically used for disk- or CPU-intensive tasks that might be obtrusive or cause system slowdown. The `renice` command can be used to reset the priority of running processes or control the priority and scheduling of all processes owned by a user. Regular users can only numerically increase process priorities (that is, make tasks less important) with this command, but a user with super-user privileges can use `sudo` to access the full `nice` range of scheduling (`-20` to `19`).

System administrators can also use the `time` command to get an idea of how much time and what proportion of a system’s resources are required for a task, such as a shell script. (Here, `time` is used to measure the duration of elapsed time; the command that deals with civil and sidereal time is the `date` command.) This command is used with the name of another command (or script) as an argument like this:

```
matthew@seymour:~$ sudo time -p find / -name conky
/home/matthew/conky
/etc/conky
/usr/lib/conky
/usr/bin/conky
real 30.19
user 1.09
sys 2.77
```

Download from www.eBookTM.com
Output of the command displays the time from start to finish, along with the user and system time required. Other factors you can query include memory, CPU usage, and file system input/output (I/O) statistics. See the `time` command’s man page for more details.

Nearly all graphical process-monitoring tools include some form of process control or management. Many of the early tools ported to Linux were clones of legacy UNIX utilities. One familiar monitoring (and control) program is `top`. Based on the `ps` command, the `top` command provides a text-based display of constantly updated console-based output showing the most CPU-intensive processes currently running. It can be started like this:

```
matthew@seymour:~$ top
```

After you press Enter, you see a display as shown in Figure 12.1. The `top` command has a few interactive commands: Pressing `h` displays the help screen; pressing `k` prompts you to enter the `pid` of a process to kill; pressing `n` prompts you to enter the `pid` of a process to change its nice value. The `top` man page describes other commands and includes a detailed description of what all the columns of information `top` can display actually represent; have a look at top’s well-written `man` page.

```
      PID  USER      PR  NI  VIRT  RES   SHR   S   %CPU %MEM    TIME+  COMMAND
1027 root      20   0  163m  31m   0s  S   0.4s  0.4%   0:01.07  xorg

```

**FIGURE 12.1** The `top` command can be used to monitor and control processes.

The `top` command displays quite a bit of information about your system. Processes can be sorted by PID, age, CPU or memory usage, time, or user. This command also provides process management, and system administrators can use its `k` and `r` keypress commands to kill and reschedule running tasks, respectively.

The `top` command uses a fair amount of memory, so you want to be judicious in its use and not leave it running all the time. When you’ve finished with it, simply press `q` to quit `top`. 
Displaying Free and Used Memory with free

Although top includes some memory information, the free utility displays the amount of free and used memory in the system in kilobytes (the -m switch displays in megabytes).

On one system, the output looks like this:

```
matthew@seymour:~$ free
          total       used       free     shared    buffers     cached
Mem:     4055680    3327764     727916          0     280944    2097568
-/+ buffers/cache:     949252    3106428
Swap:      8787512          0    8787512
```

This output describes a machine with 4GB of RAM memory and a swap partition of 8GB. Note that none of the swap is being used, and that the machine is not heavily loaded. Linux is very good at memory management and “grabs” all the memory it can in anticipation of future work.

TIP

A useful trick is to employ the watch command; it repeatedly reruns a command every two seconds by default. If you use

```
matthew@seymour:~$ watch free
```

you can see the output of the free command updated every two seconds. Use Ctrl-C to quit.

Another useful system-monitoring tool is vmstat (virtual memory statistics). This command reports on processes, memory, I/O, and CPU, typically providing an average since the last reboot; or you can make it report usage for a current period by telling it the time interval in seconds and the number of iterations you desire, like this:

```
matthew@seymour:~$ vmstat 5 10
```

This runs vmstat every five seconds for 10 iterations.

Use the uptime command to see how long it has been since the last reboot and to get an idea of what the load average has been; higher numbers mean higher loads.

Disk Space

Along with system load it is important to keep an eye on the amount of free hard drive space that your computer has remaining.

It’s very easy to do this, mainly by using the df command, like this:

```
matthew@seymour:~$ df
```

Just using the command alone returns this output:

```
Filesystem 1K-blocks Used Available Use% Mounted on
/dev/sda1 14421344 6584528 7104256 49% /
none 2020124 348 2019776 1% /dev
none 2027840 2456 2025384 1% /dev/shm
```
Here you can see each drive as mounted on your system, as well as the used space, the available space, the percentage of the total usage of the disk, and finally where it is mounted on your system.

Unless you are good at doing math in your head, you may find it difficult to work out exactly what the figures mean in megabytes and gigabytes, so it's recommended that you use the `-h` switch to make the output human readable, like this:

```
matthew@seymour:~$ df -h
```

### Disk Quotas

Disk quotas are a way to restrict the usage of disk space either by user or by groups. Although rarely—if ever—used on a local or standalone workstation, quotas are definitely a way of life at the enterprise level of computing. Usage limits on disk space not only conserve resources, but also provide a measure of operational safety by limiting the amount of disk space any user can consume.

Disk quotas are more fully covered in Chapter 10, “Managing Users.”

### Graphical Process and System Management Tools

The GNOME and KDE desktop environments offer a rich set of network and system-monitoring tools. Graphical interface elements, such as menus and buttons, and graphical output, including metering and real-time load charts, make these tools easy to use. These clients, which require an active X session and (in some cases) root permission, are included with Ubuntu.

If you view the graphical tools locally while they are being run on a server, you must have X properly installed and configured on your local machine. Although some tools can be used to remotely monitor systems or locally mounted remote file systems, you have to properly configure pertinent X11 environment variables, such as `$DISPLAY`, to use the software or use the `ssh` client's `-X` option when connecting to the remote host.
System Monitor

The first place to look in the standard Ubuntu desktop for a graphical monitoring tool is in the menu at System, Administration, System Monitor. This tool is informative, easy to use and understand, and very useful. It has tabs for information about your system configuration, running processes, available resources, and local file systems (Figures 12.2 to 12.5).

FIGURE 12.2 The System tab in System Monitor.

FIGURE 12.3 The Processes tab in System Monitor.
FIGURE 12.4  The Resources tab in System Monitor.

FIGURE 12.5  The File Systems tab in System Monitor.
Conky
Conky is a highly configurable, rather complex system monitor that is light on system resources and can give you information about nearly anything. The downside is that you need to learn how to configure it. Simply installing Conky from the software repositories only gets you started. However, for those of us who want specific information displayed on our desktop at all times, it is invaluable and well worth the time it takes to figure it out. We give an example here, but to truly appreciate the power, flexibility, and possibilities of Conky, visit http://conkyhardcore.com/ and this long-running thread on the Ubuntu Forums http://ubuntuforums.org/showthread.php?t=281865.

Conky uses text files for configuration and is often started using a short script. The example shown in Figure 12.6 is from Matthew's personal configuration on his laptop and is intended as a simple example to get you started.

![Conky Example](image-url)
In this example, Conky gives information about the kernel, the operating system, the hostname of the system, and the current time and date. It continually updates with information on load averages, CPU usage and temperature, battery status, RAM and disk usage. In addition, it shows networking details, including the internal network IP address and the IP address assigned to the outside-facing router the network uses to connect to the wider world and current inbound and outbound network connections. (The IP address is assigned by the ISP, and it changes, so if you try to attack Matthew's home network using it, you will find that the IP address is being used by someone else now). That is a lot of information in a small space. This setup isn't as pretty as some you will see at the previous links, nearly all of which have their setup details made freely available by the person who wrote the configurations.

In this example, Matthew is using two files to run Conky. The first is called conkyrc and is a text file that includes the configuration details for what you see in Figure 12.6:

```bash
# Use Xft?
use_xft yes

# Xft font when Xft is enabled
xtffont InconsolataSSi:size=9

# gap is the number of pixels from the starting point under alignment
#minimum_size 10 10
gap_x 13
gap_y 45

# Text alignment, other possible values are commented#alignment top_left
alignment top_right
#alignment bottom_left
#alignment bottom_right

# Add spaces to keep things from moving about?  This only affects certain objects.
use_spacer right

# Subtract file system buffers from used memory?
no_buffers yes

# Use double buffering (reduces flicker, may not work for everyone)
double_buffer yes

# Allows icons to appear, window to be moved, and transparency
own_window yes
```
own_window_type override
own_window_transparent yes
#own_window_hints undecorated,below,skip_taskbar

# set to yes if you want Conky to be forked in the background
cpu_avg_samples 1
net_avg_samples 1

# Update interval in seconds
update_interval 1

# -- start display config --

Total upload: $totalup eth0
Download speed: $downspeed eth0
Upload speed: $upspeed eth0

Public IP $execi 5 curl 'http://***a-website-that-returns-your-ip-address—see below***'

Port(s) / Connections:
Inbound: $tcp_portmon 1 32767 count
Outbound: $tcp_portmon 32768 61000 count
Total: $tcp_portmon 1 65535 count
Outbound Connection $alignr Remote Service/Port$
Most of these details are clear, but one is particularly interesting. There are commercial and other sites that, if you visit them, will return your IP address. This is easily accomplished several ways. Matthew chose to put the following PHP in a file on a server he owns and he calls it directly. Doing so can help you not to feel guilty about constantly hitting someone else's server for this information.

```php
<?
    $remote = $_SERVER['REMOTE_ADDR'];
    echo $remote;
?>
```

Finally, although you can run conky from the command line at any time after it is set up, to make it more convenient many people choose to keep their config files in their /home directory somewhere and then write a script with the custom location. If you add a pause to the beginning of the script, then you can add the script to System, Preferences, Startup Applications and have it come up after all your other desktop processes are up and running. Here is a simple example:

```bash
#!/bin/bash
sleep 45 &&
exec conky -d -c ~/conky/conkyrc &
# sleep 50 &&
# exec conky -d -c ~/conky/conkyrc_weather &
exit
```

Save it in /home/username/conky along with all your conky config files, make it executable, then have the startup applications process call it at boot. Notice that this way you can also run more than one instance of Conky at a time, perhaps having your regular instance in the upper right of the screen and a weather instance or something else in a different location. The possibilities are vast.

**Other**

Some of the graphical system- and process-monitoring tools that come with Ubuntu include the following:

- **vncviewer**—AT&T's open source remote session manager (part of the Xvnc package), which can be used to view and run a remote desktop session locally. This software (discussed in more detail in Chapter 15, “Remote Access with SSH and Telnet”) requires an active, background, X session on the remote computer.
gnome-nettool—A GNOME-developed tool that enables system administrators to carry out a wide range of diagnostics on network interfaces, including port scanning and route tracing.

ethtool—This graphical network protocol analyzer can be used to save or display packet data in real time and has intelligent filtering to recognize data signatures or patterns from a variety of hardware and data captures from third-party data capture programs, including compressed files. Some protocols include AppleTalk, Andrew File System (AFS), AOL’s Instant Messenger, various Cisco protocols, and many more.

KDE Process- and System-Monitoring Tools

KDE provides several process- and system-monitoring clients. Integrate the KDE graphical clients into the desktop taskbar by right-clicking the taskbar and following the menus. These KDE monitoring clients include the following:

- kdf—A graphical interface to your system’s file system table that displays free disk space and enables you to mount and unmount file systems with a pointing device.

- ksysguard—Another panel applet that provides CPU load and memory use information in animated graphs.

Enterprise Server Monitoring

Servers used in enterprise situations require extreme uptime. It is beyond the scope of this book to discuss topics such as redundancy, fail-safe and fail-over safeguards, and so on. However, there are a couple of tools we wanted to mention to help an enterprise sysadmin get started.

Landscape

Canonical, the company that finances much of the Ubuntu development, has a monitoring service incorporated into its systems administration tool, Landscape. Landscape has a special dashboard that gives monitoring information and creates an interface for managing multiple Ubuntu systems easily including Ubuntu Enterprise Cloud and Amazon EC2 installations. For more information, see www.canonical.com/enterprise-services/landscape.

Other

There are a myriad of quality monitoring tools available. We have only touched on one of the more basic options. For more information about other enterprise server monitoring options, such as Zenoss and Nagios, take a look at https://help.ubuntu.com/community/Servers#Monitoring.

- http://and.sourceforge.net/—Home page of the auto nice daemon (AND), which can be used to prioritize and reschedule processes automatically.
CHAPTER 13

Backing Up

This chapter examines the practice of safeguarding data by creating backup copies, restoring that same data if necessary, and recovering data in case of a catastrophic hardware or software failure. The chapter gives you a full understanding of the reasons for sound backup practices. You can use the information here to make intelligent choices about which strategies are best for you. The chapter also shows you how to perform some types of data recovery and system restoration on your own and gives guidance on when to seek professional assistance.

Choosing a Backup Strategy

Backups are always trade-offs. Any backup will consume time, money, and effort on an ongoing basis; backups must be monitored, validated, indexed, stored, and new media continuously purchased. Sound expensive? The cost of not having backups is the loss of your critical data. Re-creating the data from scratch will cost time and money, and if the cost of doing it all again is greater than the cost associated with backing up, you should be performing backups. At the foundation, backups are nothing more than insurance against financial loss for you or your business.

Your first step in formulating and learning to use an effective backup strategy is to choose the strategy that is right for you. First, you must understand some of the most common (and not so common) causes of data loss so that you are better able to understand the threats your system faces. Then, you need to assess your own system, how it is used and by whom, your available hardware and software resources, and your budget constraints. The following
sections look at each of these issues in detail, as well as offering some sample backup systems and discussing their use.

**Why Data Loss Occurs**

Files disappear for any number of reasons: They can be lost because the hardware fails and causes data loss; your attention might wander and you accidentally delete or overwrite a file. Some data loss occurs as a result of natural disasters, and other circumstances beyond your control. A tornado, flood, or earthquake could strike, the water pipes could burst, or the building could catch on fire. Your data, as well as the hardware, would likely be destroyed in such a disaster. A disgruntled employee might destroy files or hardware in an attempt at retribution. And any equipment might fail, and it all will fail at some time—most likely when it is extremely important for it not to fail.

**A CASE IN POINT**

A recent Harris poll of Fortune 500 executives found that roughly two-thirds of them had problems with their backups and disaster-recovery plans. How about you?

Data can also be lost because of malfunctions that corrupt the data as it attempts to write to the disk. Other applications, utilities, and drivers might be poorly written, buggy (the phrase most often heard today is “still beta quality”), or might suffer some corruption and fail to correctly write that all-important data you have just created. If that happened, the contents of your data file would be indecipherable garbage of no use to anyone.

All these accidents and disasters offer important reasons for having a good backup strategy; however, the most frequent cause of data loss is human error. Who among us has not overwritten a new file with an older version or unintentionally deleted a needed file? This applies not only to data files, but also to configuration files and binaries. While perusing the mail lists, Usenet newsgroup postings, or online forums, stories about deleting entire directories such as `/home`, `/usr`, or `/lib` seem all too common. On a stable server that is not frequently modified or updated, you can choose to mount `/usr` read-only to prevent writing over or deleting anything in it. Incorrectly changing a configuration file and not saving the original in case it has to be restored (which happens more often than not because the person reconfigured it incorrectly) is another common error.

**TIP**

To make a backup of a configuration file you are about to edit, use the `cp` command:

```
matthew@seymour:-$ cp filename filename.original
```

And to restore it:

```
matthew@seymour:-$ cp filename.original filename
```

Never edit or move the `*.original` file, or the original copy will be lost. You can change the file’s mode to be unwritable, so that if you try to delete it, you will prevent and will receive a warning.
Proper backups can help you recover from these problems with a minimum of hassle, but you have to put in the effort to keep backups current, verify they are intact, and practice restoring the data in different disaster scenarios.

**Assessing Your Backup Needs and Resources**

By now you have realized that some kind of plan is needed to safeguard your data, and, like most people, you are overwhelmed by the prospect. Entire books, as well as countless articles and whitepapers, have been written on the subject of backing up and restoring data. What makes the topic so complex is that each solution is truly individual.

Yet, the proper approach to making the decision is very straightforward. You start the process by asking:

- What data must be safeguarded?
- How often does the data change?

The answers to these two questions determine how important the data is, determine the volume of the data, and determine the frequency of the backups. This in turn will determine the backup medium. Only then can the software be selected that will accommodate all these considerations. (You learn about choosing backup software, hardware, and media later in this chapter.)

Available resources are another important consideration when selecting a backup strategy. Backups require time, money, and personnel. Begin your planning activities by determining what limitations you face for all these resources. Then, construct your plan to fit those limitations, or be prepared to justify the need for more resources with a careful assessment of both backup needs and costs.

**TIP**

If you are not willing or capable of assessing your backup needs and choosing a backup solution, there are legions of consultants, hardware vendors, and software vendors who would love to assist you. The best way to choose one in your area is to ask other UNIX and Linux system administrators (located through user groups, discussion groups, or mail lists) who are willing to share their experiences and make recommendations. If you cannot get a referral, ask the consultant for references and check them out.

Many people also fail to consider the element of time when formulating their plan. Some backup devices are faster than others, and some recovery methods are faster than others. You need to consider that when making choices.

To formulate your backup plan, you need to determine the frequency of backups. The necessary frequency of backups should be determined by how quickly the important data on your system changes. On a home system, most files never change, a few change daily, and some change weekly. No elaborate strategy needs to be created to deal with that. A good strategy for home use is to back up (to any kind of removable media) critical data frequently and back up configuration and other files weekly.
At the enterprise level on a larger system with multiple users, a different approach is called for. Some critical data is changing constantly, and it could be expensive to re-create; this typically involves elaborate and expensive solutions. Most of us exist somewhere in between these extremes. Assess your system and its use to determine where you fall in this spectrum.

Backup schemes and hardware can be elaborate or simple, but they all require a workable plan and faithful follow-through. Even the best backup plan is useless if the process is not carried out, data is not verified, and data restoration is not practiced on a regular basis. Whatever backup scheme you choose, be sure to incorporate in it these three principles:

- **Have a plan**—Design a plan that is right for your needs and have equipment appropriate to the task. This involves assessing all the factors that affect the data you are backing up. We will get into more detail later in the chapter.

- **Follow the plan**—Faithfully complete each part of your backup strategy, and then verify the data stored in the backups. Backups with corrupt data are of no use to anyone. Even backup operations can go wrong.

- **Practice your skills**—Practice restoring data from your backup systems from time to time, so when disaster strikes, you are ready (and able) to benefit from the strength of your backup plan. (For restoring data, see the section, “Using Backup Software.”) Keep in mind that it is entirely possible that the flaws in your backup plan will only become apparent when you try restoring!

### SOUND PRACTICES

You have to create your own best-backup plan, but here are some building blocks that go into the foundation of any sound backup program:

- Maintain more than one copy of critical data.
- Label the backups.
- Store the backups in a climate-controlled and secure area.
- Use secure, offsite storage of critical data. Many companies choose bank vaults for their offsite storage, and this is highly recommended.
- Establish a backup policy that makes sense and can be followed religiously. Try to back up your data when the system is consistent (that is, no data is being written), which is usually overnight.
- Keep track of who has access to your backup media, and keep the total number of people as low as possible. If you can, allow only trusted personnel near your backups.
- Routinely verify backups and practice restoring data from them.
- Routinely inspect backup media for defects and regularly replace them (after destroying the data on them if it is sensitive).
Evaluating Backup Strategies

Now that you are convinced you need backups, you need a strategy. It is difficult to be specific about an ideal strategy because each user or administrator’s strategy will be highly individualized, but here are a few general examples:

- **Home user**—At home, the user has the Ubuntu installation DVD that takes less than an hour to reinstall, so the time issue is not a major concern. The home user will want to back up any configuration files that have altered, keep an archive of any files that have been downloaded, and keep an archive of any data files created while using any applications. Unless the home user has a special project in which constant backups are useful, a weekly backup is probably adequate. The home user will likely use a DVD-RW, external hard drive or other removable media for backups.

- **Small office**—Many small offices tend to use the same strategy as the home user, but are more likely to back up critical data daily and use manually changed tape drives. If they have a tape drive with adequate storage, they will likely have a full system backup as well because restoring from the tape is quicker than reinstalling from the CDs. They also might be using a CD-RW or DVD writers for backups. Although they will use scripts to automate backups, most of it is probably done by hand.

- **Small enterprise**—Here is where backups begin to require higher-end equipment such as autoloading tape drives with fully automated backups. Commercial backup software usually makes an introduction at this level, but a skillful system administrator on a budget can use one of the basic applications discussed in this chapter. Backups are highly structured and supervised by a dedicated system administrator.

- **Large enterprise**—These are the most likely setting for the use of expensive, proprietary, highly automated backup solutions. At this level, data means money, lost data means lost money, and delays in restoring data means money lost as well. These system administrators know that backups are necessary insurance and plan accordingly.

Does all this mean that enterprise-level backups are better than those done by a home user? Not at all. The “little guy” with Ubuntu can do just as well as the enterprise operation at the expense of investing more time in the process. By examining the higher-end strategies, we can apply useful concepts across the board.

**NOTE**

If you are a new sysadmin, you might be inheriting an existing backup strategy. Take some time to examine it and see if it meets the current needs of the organization. Think about what backup protection your organization really needs, and determine if the current strategy meets that need. If it does not, change the strategy. Consider whether the current policy is being practiced by the users, and, if not, why it is not.
UNIX uses the concept of backup levels as a shorthand way of referring to how much data is backed up in relation to a previous backup. It works this way:

A level 0 backup is a full backup. The next backup level would be 1.

Backups at the other numbered levels will back up everything that has changed since the last backup at that level or a numerically higher level (the dump command, for example, offers 10 different backup levels). For example, a level 3 followed by a level 4 will generate an incremental backup from the full backup, whereas a level 4 followed by a level 3 will generate a differential backup between the two.

The following sections examine a few of the many strategies in use today. Many strategies are based on these sample schemes; one of them can serve as a foundation for the strategy you construct for your own system.

**Simple Strategy**

If you need to back up just a few configuration files and some small data files, copy them to a USB stick, engage the write-protect tab, and keep it someplace safe. If you need just a bit more backup storage capacity, you can copy the important files to a CD-RW disk (up to 700MB in size), or a DVD-RW disk (up to 8GB for data). Many users have switched to using an external hard drive for backups because they are becoming less and less expensive and hold a great amount of data.

In addition to configuration and data files, you should archive each user’s home directory, as well as the entire `/etc` directory. Between the two, that backup would contain most of the important files for a small system. Then, you can easily restore this data from the backup media device you have chosen, after a complete reinstall of Ubuntu, if necessary.

Experts used to say that if you have more data than can fit on a floppy disk, you really need a formal backup strategy. Because a floppy disk only held a little over 1MB (and is now incredibly obsolete), perhaps we should change that to “if you have more data than can fit on a cheap USB stick.” In any case, some formal backup strategies are discussed in the following sections. We use a tape media backup as an example for convenience because they have been incredibly popular and standard in the past and are still quite common, even as people move to new options such as portable hard drives and cloud storage.

**Full Backup on a Periodic Basis**

This backup strategy involves a backup of the complete file system on a weekly, bi-weekly, or other periodic basis. The frequency of the backup depends on the amount of data being backed up, the frequency of changes to the data, and the cost of losing those changes.

This backup strategy is not complicated to perform, and it can be accomplished with the swappable disk drives discussed later in the chapter. If you are connected to a network, it is possible to mirror the data on another machine (preferably offsite); the `rsync` tool is particularly well suited to this task. Recognize that this does not address the need for archives of the recent state of files; it only presents a snapshot of the system at the time the update is done.
Choosing a Backup Strategy

Full Backups with Incremental Backups
This scheme involves performing a full backup of the entire system once a week, along with a daily incremental backup of only those files that have changed in the previous day, and it begins to resemble what a sysadmin of a medium to large system would traditionally use.

This backup scheme can be advanced in two ways. In one way, each incremental backup can be made with reference to the original full backup. In other words, a level 0 backup is followed by a series of level 1 backups. The benefit of this backup scheme is that a restoration requires only two tapes (the full backup and the most recent incremental backup). But because it references the full backup, each incremental backup might be large (and grow ever larger) on a heavily used system.

Alternatively, each incremental backup could reference the previous incremental backup. This would be a level 0 backup followed by a level 1, followed by a level 2, and so on. Incremental backups are quicker (less data each time), but require every tape to restore a full system. Again, it is a classic trade-off decision.

Modern commercial backup applications such as Amanda or BRU assist in organizing the process of managing complex backup schedules and tracking backup media. Doing it yourself using the classic dump or employing shell scripts to run tar requires that the system administrator handle all the organization herself. For this reason, complex backup situations are typically handled with commercial software and specialized hardware that are packaged, sold, and supported by vendors.

Mirroring Data or RAID Arrays
Given adequate (and often expensive) hardware resources, you can always mirror the data somewhere else, essentially maintaining a real-time copy of your data on hand. This is often a cheap, workable solution if no large amounts of data are involved. The use of RAID arrays (in some of their incarnations) provides for a recovery if a disk fails.

Note that RAID arrays and mirroring systems will just as happily write corrupt data as valid data. Moreover, if a file is deleted, a RAID array will not save it. RAID arrays are best suited for protecting the current state of a running system, not for backup needs.

Making the Choice
Only you can decide what is best for your situation. After reading about the backup options in this book, put together some sample backup plans; run through a few likely scenarios and assess the effectiveness of your choice.

In addition to all the other information you have learned about backup strategies, here are a couple of good rules of thumb to remember when making your choice:

- If the backup strategy and policy is too complicated (and this holds true for most security issues), it will eventually be disregarded and fall into disuse.
- The best scheme is often a combination of strategies; use what works.
Choosing Backup Hardware and Media

Any device that can store data can be used to back it up, but that is like saying that anything with wheels can take you on a cross-country trip. Trying to fit ten gigabytes worth of data on a big stack of CD-RWs is an exercise in frustration, and using an expensive automated tape device to save a single copy of an email is a waste of resources.

Many people use what hardware they already have for their backup operations. Many consumer-grade workstations have a DVD-RW drive, but they typically do not have the abundant free disk space necessary for performing and storing multiple full backups.

In this section, you learn about some of the most common backup hardware available and how to evaluate its appropriateness for your backup needs. With large storage devices becoming increasingly affordable (2terabyte hard drives can now be had for around $100), decisions about backup hardware for the small business and home users have become more interesting.

Removable Storage Media

Choosing the right media isn’t as easy as it used to be when floppy drives were the only choice. Today, most machines have DVD-ROM drives that can read but not write DVDs, which rules them out for backup purposes. Instead, USB hard drives and solid-state “pen” drives have taken over the niche previously held by floppy drives: you can get a 4GB drive for under $10.00, and you can even get capacities up to 128GB for good prices if you shop around. Both USB hard drives and solid-state drives are highly portable. Support for these drives under Ubuntu is very good and the storage space is rising although prices are falling constantly. A 1TB USB external hard drive will cost about $50.00. The biggest benefits of USB drives are data transfer speed and portability.

CD-RW and DVD+RW/-RW Drives

Compared to floppy drives and some removable drives, CD-RW drives and their cousins, DVD+RW/-RW drives, can store large amounts of data and are useful for a home or small business. CD writers and media that were once very expensive are at commodity prices today, although automated CD changing machines, necessary for automatically backing up large amounts of data, are still quite costly. A benefit of CD and DVD storage over tape devices is that the archived uncompressed file system can be mounted and its files accessed randomly just like a hard drive (you do this when you create a data CD, see Chapter 7, “Multimedia Applications”), making the recovery of individual files easier.

Each CD-RW disk can hold 650MB–700MB of data (the media comes in both capacities at roughly the same cost); larger chunks of data can be split to fit on multiple disks. Some backup programs support this method of storage. After they are burned and verified, the shelf life for the media is at least a decade or longer.

DVD+RW/-RW is similar to CD-RW, but it is more expensive and can store up to 8GB of uncompressed data per disk.
Honestly, though, these are an old technology and, although they haven’t completely died off, the use of either CDs or DVDs for backup has dropped off considerably. It won’t be long before they become almost as rare as floppy disks and drives.

**Network Storage**

For network backup storage, remote arrays of hard drives provide one solution to data storage. With the declining cost of mass storage devices and the increasing need for larger storage space, network storage (NAS or Network Attached Storage) is available and supported in Linux. These are cabinets full of hard drives and their associated controlling circuitry, as well as special software to manage all of it. These NAS systems are connected to the network and act as a huge (and expensive) mass storage device.

More modest and simple network storage can be done on a remote desktop-style machine that has adequate storage space (up to eight 1TB drives is a lot of storage space, easily accomplished with off-the-shelf parts), but then that machine (and the local system administrator) has to deal with all the problems of backing up, preserving, and restoring its own data, doesn’t it? Several hardware vendors offer such products in varying sizes.

**Tape Drive Backup**

Tape drives have been used in the computer industry from the beginning. Tape drive storage has been so prevalent in the industry that the `tar` command (the most commonly used command for archiving) is derived from the words Tape ARchive. Capacities and durability of tapes vary from type to type and range from a few gigabytes to hundreds of gigabytes with commensurate increases in cost for the equipment and media. Autoloading tape-drive systems can accommodate archives that exceed the capacity of the file systems.

**TIP**

Older tape equipment is often available in the used equipment market and might be useful for smaller operations that have outgrown more limited backup device options.

Tape equipment is well supported in Linux and, when properly maintained, is extremely reliable. The tapes themselves are inexpensive, given their storage capacity and the ability to reuse them. Be aware, however, that tapes do deteriorate over time and, being mechanical, tape drives can and will fail.

**CAUTION**

Neglecting to clean, align, and maintain tape drives puts your data at risk. The tapes themselves are also susceptible to mechanical wear and degradation. Hardware maintenance is part of a good backup policy. Do not ever forget that it is a question of when—not if—hardware will fail.
Cloud Storage

Services such as Amazon’s AWS and S3 or Canonical’s Ubuntu One offer a way to create and store backups offsite. Larger companies may create their own offsite, online storage options as well. In each of these and similar cases, data is copied and stored remotely on a file server set aside specifically for that purpose. The data backups may be scheduled with great flexibility and according to the plans and desires of the customer. These are generally more expensive options than the average home user may need, but not always as shown by Ubuntu One’s offer of up to 2GB of free storage that is easily kept in sync with your Ubuntu desktop with an option to increase the space for a fee.

Cloud storage is a backup solution that is recent and growing in popularity, but it is also a technology that is changing rapidly. To learn more about the options mentioned here, take a look at https://one.ubuntu.com/ and http://aws.amazon.com/s3/. Although these are not the only services of the kind available, they offer a good introduction to the concept. If you like to roll your own, you definitely want to take a look at Ubuntu Enterprise Cloud at www.ubuntu.com/cloud.

Using Backup Software

Because there are thousands of unique situations requiring as many unique backup solutions, it comes as no surprise that Linux offers many backup tools. Along with command-line tools such as tar and dd, Ubuntu also provides a graphical archiving tool, File Roller, that can create and extract files from archives. Ubuntu also provides support for the Amanda backup application—a sophisticated backup application that works well over network connections and can be configured to automatically back up all the computers on your network. Amanda works with drives as well as tapes.

NOTE

The software in a backup system must support the hardware, and this relationship can determine which hardware or software choices you make. Many sysadmins choose particular backup software not because they prefer it to other options, but because it supports the hardware they own.

The price seems right for free backup tools, but consider the software’s ease of use and automation when assessing costs. If you must spend several hours implementing, debugging, documenting, and otherwise dealing with overly elaborate automation scripts, the real costs go up.

**tar: The Most Basic Backup Tool**

The `tar` tool, the bewhiskered old man of archiving utilities, is installed by default. It is an excellent tool for saving entire directories full of files. For example, here is the command used to back up the `/etc` directory:

```
matthew@seymour:~$ sudo tar cvf etc.tar /etc
```
Here, the options use `tar` to create an archive, be verbose in the message output, and use the filename `etc.tar` as the archive name for the contents of the directory `/etc`.

Alternatively, if the output of `tar` is sent to the standard output and redirected to a file, the command appears as follows:

```
matthew@seymour:~$ sudo tar cv /etc > etc.tar
```
and the result is the same.

All files in the `/etc` directory will be saved to a file named `etc.tar`. With an impressive array of options (see the `man` page), `tar` is quite flexible and powerful in combination with shell scripts. With the `-z` option, it can even create and restore gzip compressed archives while the `-j` option works with bzipped files.

### Creating Full and Incremental Backups with tar

If you want to create a full backup, the following will create a bzip2 compressed tarball (the `j` option) of the entire system:

```
matthew@seymour:~$ sudo tar cjvf fullbackup.tar.bz2 /
```

To perform an incremental backup, you must locate all the files that have been changed since the last backup. For simplicity, assume that you do incremental backups on a daily basis. To locate the files, use the `find` command:

```
matthew@seymour:~$ sudo find / -newer name_of_last_backup_file ! -a -type f -print
```

When run alone, `find` will generate a list of files system wide and print it to the screen. The `! -a -type` eliminates everything but regular files from the list; otherwise, the entire directory would be sent to `tar` even if the contents were not all changed.

Pipe the output of our `find` command to `tar` as follows:

```
matthew@seymour:~$ sudo find / -newer name_of_last_backup_file ! -type d -print |\
  tar czT - backup_file_name_or_device_name
```

Here, the `T` - option gets the filenames from a buffer (where the `-` is the shorthand name for the buffer).

---

**NOTE**

The `tar` command can back up to a raw device (one with no file system) as well as a formatted partition. For example,

```
matthew@seymour:~$ sudo tar cvzf /dev/hdd /boot /etc /home
```
backs up those directories to device `/dev/hdd` (not `/dev/hda1`, but to the unformatted device itself).

The `tar` command can also back up over multiple floppy disks:

```
matthew@seymour:~$ sudo tar czvMf /dev/fd0 /home
```
This will back up the contents of /home and spread the file out over multiple floppies, prompting you with this message:

Prepare volume #2 for '/dev/fd0' and hit return:

**Restoring Files from an Archive with tar**
The `xp` option in `tar` will restore the files from a backup and preserve the file attributes as well, and `tar` will create any subdirectories it needs. Be careful when using this option because the backups might have been created with either relative or absolute paths. You should use the `tvf` option with `tar` to list the files in the archive before extracting them so that you will know where they will be placed.

For example, to restore a `tar` archive compressed with `bzip2`,

```bash
matthew@seymour:~$ sudo tar xjvf ubuntutest.tar.bz2
```

To list the contents of a `tar` archive compressed with `bzip2`,

```bash
matthew@seymour:~$ sudo tar tjvf ubuntutest.tar.bz2
```

```
tar: Record size = 8 blocks
```

```
drwxr-xr-x matthew/matthew 0 2010-07-08 14:58 other/
-rwxr-xr-x matthew/matthew 1856 2010-04-29 14:37 other/matthew helmke public.asc
-rwxr-xr-x matthew/matthew 170 2010-05-28 18:11 backup.sh
-rwxr-xr-x matthew/matthew 1593 2009-10-11 10:38 backup method
```

Note that because the pathnames do not start with a backslash, they are relative pathnames and will install in your current working directory. If they were absolute pathnames, they would install exactly where the paths state.

**The GNOME File Roller**
The GNOME desktop file archiving graphical application File Roller (`file-roller`) will view, extract, and create archive files using `tar`, `gzip`, `bzip`, `compress`, `zip`, `rar`, `lha`, and several other compression formats. Note that File Roller is only a front-end to the command-line utilities that actually provide these compression formats; if they are not installed, File Roller cannot use that format.

---

**CAUTION**

File Roller will not complain if you select a compression format that is not supported by installed software until after you attempt to create the archive. Install any needed compression utilities first.
File Roller is well-integrated with the GNOME desktop environment to provide convenient drag-and-drop functionality with the Nautilus file manager. To create a new archive, select Archive, New to open the New Archive dialog box, and navigate to the directory where you want the archive to be kept. Type your archive’s name in the Selection: /root text box at the bottom of the New Archive dialog box. Use the Archive type drop-down menu to select a compression method. Now, drag the files that you want to be included from Nautilus into the empty space of the File Roller window, and the animated icons will show that files are being included in the new archive. When you are done, a list of files will be shown in the previously blank File Roller window. To save the archive, simply select Archive, Close. Opening an archive is as easy as using the Archive, Open dialog to select the appropriate archive file. You can learn more at https://help.ubuntu.com/community/File%20Roller.

Ubuntu also offer the KDE ark and kdat GUI tools for backups; they are installed only if you select the KDE desktop during installation, but you can search through Synaptic to find them. Archiving has traditionally been a function of the system administrator and not seen as a task for the individual user, so no elaborate GUI was believed necessary. Backing up has also been seen as a script driven, automated task in which a GUI is not as useful. Although that’s true for sysadmins, home users usually want something a little more attractive and easier to use, and that's the gap ark was created to fill.

The KDE ark Archiving Tool

You launch ark by launching it from the command line. It is integrated with the KDE desktop (such as File Roller is with GNOME), so it might be a better choice if you use KDE. This application provides a graphical interface to viewing, creating, adding to, and extracting from archived files. Several configuration options are available with ark to ensure its compatibility with MS Windows. You can drag and drop from the KDE desktop or Konqueror file browser to add or extract files, or you can use the ark menus.

As long as the associated command-line programs are installed, ark can work with tar, gzip, bzip2, zip, and lha files (the latter four being compression methods used to save space by compaction of the archived files).

Existing archives are opened after launching the application itself. You can add files and directories to the archive or delete them from the archive. After opening the archive, you can extract all of its contents or individual files. You can also perform searches using patterns (all *.jpg files, for example) to select files.

Choosing New from the File menu creates new archives. You then type the name of the archive, providing the appropriate extension (.tar, .gz, and so on), and then proceed to add files and directories as you desire.

Using the Amanda Backup Application

Provided with Ubuntu, Amanda is a powerful, network backup application created by the University of Maryland at College Park. Amanda is a robust backup and restore application best suited to unattended backups with an autoloading tape drive of adequate capacity. It benefits from good user support and documentation.
Amanda’s features include compression and encryption. It is intended for use with high-capacity tape drives, floptical, CD-R, and CD-RW devices.

Amanda uses GNU tar and dump; it is intended for unattended, automated tape backups, and is not well suited for interactive or ad hoc backups. The support for tape devices in Amanda is robust, and file restoration is relatively simple. Although Amanda does not support older Macintosh clients, it will use Samba to back up Microsoft Windows clients, as well as any UNIX client that can use GNU tools (which includes Mac OS X). Because Amanda runs on top of standard GNU tools, file restoration can be made using those tools on a recovery disk even if the Amanda server is not available. File compression can be done on either the client or server, thus lightening the computational load on less powerful machines that need backing up.

**CAUTION**

Amanda does not support dump images larger than a single tape and requires a new tape for each run. If you forget to change a tape, Amanda continues to attempt backups until you insert a new tape, but those backups will not capture the data as you intended them to. Do not use too small a tape or forget to change a tape, or you will not be happy with the results.

There is no GUI interface for Amanda. Configuration is done in the time-honored UNIX tradition of editing text configuration files located in /etc/amanda. The default installation in Ubuntu includes a sample cron file because it is expected that you will be using cron to run Amanda regularly. The client utilities are installed with the package amanda-client; the Amanda server is called amanda-server. Install both. As far as backup schemes are concerned, Amanda calculates an optimal scheme on-the-fly and schedules it accordingly. It can be forced to adhere to a traditional scheme, but other tools are possibly better suited for that job.

The man page for Amanda (the client is amdump) is well written and useful, explaining both the configuration of Amanda as well as detailing the several programs that actually make up Amanda. The configuration files found in /etc/amanda are well commented; they provide a number of examples to assist you in configuration.

The program’s home page is www.amanda.org. There, you will find information on subscribing to the mail list, as well as links to Amanda-related projects and a FAQ.

**Alternative Backup Software**

Commercial and other freeware backup products do exist; BRU and Veritas are good examples of effective commercial backup products. Here are some useful free software backup tools that are not installed with Ubuntu:

- **flexbackup**—This backup tool is a large file of Perl scripts that makes dump and restore easier to use. flexbackup’s command syntax can be found by using the command with the -help argument. It also can use afio, cpio, and tar to create and
Copying Files

Often, when you have only a few files that you need to protect from loss or corruption, it might make better sense to simply copy the individual files to another storage medium rather than to create an archive of them. You can use the `tar`, `cp`, `rsync`, or even the `cpio` commands to do this, as well as a handy file management tool known as `mc`. Using `tar` is the traditional choice because older versions of `cp` did not handle symbolic links and permissions well at times, causing those attributes (characteristics of the file) to be lost; `tar` handled those file attributes in a better manner. `cp` has been improved to fix those problems, but `tar` is still more widely used. `rsync` has recently been added to Ubuntu and is an excellent choice for mirroring sets of files, especially when done over a network.

To illustrate how to use file copying as a backup technique, the examples here show how to copy (not archive) a directory tree. This tree includes symbolic links and files that have special file permissions we need to keep intact.

Copying Files Using `tar`

One choice for copying files into another location would be to use the `tar` command where you would create a `tar` file that would be piped to `tar` to be uncompressed in the new location. To accomplish this, first change to the source directory. Then, the entire command resembles

```
matthew@seymour:$ tar cvf files ; (cd target_directory ; tar xpf)
```

In this command `files` are the filenames you want to include; use `*` to include the entire current directory.

Here is how the command shown works: You have already changed to the source directory and executed `tar` with the `cvf` arguments that tell `tar` to

- `c`—Create an archive.
- `v`—Verbose; lists the files processed so we can see that it is working.
f—The filename of the archive will be what follows. (In this case, it is -.)

The following tar commands can be useful for creating file copies for backup purposes:

l—Stay in the local file system (so you do not include remote volumes).

atime-preserve—Do not change access times on files, even though you are accessing them now, to preserve the old access information for archival purposes.

The contents of the tar file (held for us temporarily in the buffer, which is named -) are then piped to the second expression, which will extract the files to the target directory. In shell programming (refer to Chapter 11, “Automating Tasks”), enclosing an expression in parentheses causes it to operate in a subshell and be executed first.

First we change to the target directory, and then

x—Extract files from a tar archive.

p—Preserve permissions.

f—The filename will be -, the temporary buffer that holds the tared files.

Compressing, Encrypting, and Sending tar Streams

The file copy techniques using the tar command in the previous section can also be used to quickly and securely copy a directory structure across a LAN or the Internet (using the ssh command). One way to make use of these techniques is to use the following command line to first compress the contents of a designated directory, and then decompress the compressed and encrypted archive stream into a designated directory on a remote host:

```
matthew@seymour:~$ tar cvzf - data_folder | ssh remote_host '( cd ~/mybackup_dir; tar xvzf - )'
```

The tar command is used to create, list, and compress the files in the directory named data_folder. The output is piped through the ssh (secure shell) command and sent to the remote computer named remote_host. On the remote computer, the stream is then extracted and saved in the directory named /mybackup_dir. You will be prompted for a password to send the stream.

Copying Files Using cp

To copy files, we could use the cp command. The general format of the command when used for simple copying is

```
matthew@seymour:~$ cp -a source_directory target_directory
```
The -a argument is the same as giving -dpR, which would be

- d—Preserves symbolic links (by not dereferencing them) and copies the files that they point to instead of copying the links.
- p—Preserves all file attributes if possible. (File ownership might interfere.)
- R—Copies directories recursively.

The `cp` command can also be used to quickly replicate directories and retain permissions by using the -avR command-line options. Using these options preserves file and directory permissions, gives verbose output, and recursively copies and re-creates subdirectories. A log of the backup can also be created during the backup by redirecting the standard output like this:

```
matthew@seymour:~$ sudo cp -avR directory_to_backup destination_vol_or_dir 1 > /root/backup_log.txt
```

or

```
matthew@seymour:~$ sudo cp -avR ubuntu /test2 1 > /root/backup_log.txt
```

This example makes an exact copy of the directory named `ubuntu` on the volume named `/test2`, and saves a backup report named `backup_log.txt` under `/root`.

### Copying Files Using `mc`

The Midnight Commander (available in the Universe repository, under the package “mc”; see Chapter 32, “Managing Software” for how to enable the Universe and Multiverse repositories) is a command-line file manager that is useful for copying, moving, and archiving files and directories. The Midnight Commander has a look and feel similar to the Norton Commander of DOS fame. By executing `mc` at a shell prompt, a dual-pane view of the files is displayed. It contains drop-down menu choices and function keys to manipulate files. It also uses its own virtual file system, enabling it to mount FTP directories and display the contents of `tar` files, gzipped `tar` files (`.tar.gz` or `.tgz`), bzip files, DEB files, and RPM files, as well as extract individual files from them. As if that was not enough, `mc` contains a File Undelete virtual file system for ext2/3 partitions. By using `cd` to “change directories” to an FTP server’s URL, you can transfer files using the FTP protocol. The default font chosen for Ubuntu makes the display of `mc` ugly when used in a tty console (as opposed to an `xterm`), but does not affect its performance.

In the interface, pressing the F9 key drops down the menu, and pressing F1 displays the Help file. A “feature” in the default GNOME terminal intercepts the F10 key used to exit `mc`, so use F9 instead to access the menu item to quit, or simply click the menu bar at the bottom with your mouse. The configuration files are well documented, and it would appear easy to extend the functionality of `mc` for your system if you understand shell scripting and regular expressions. It is an excellent choice for file management on servers not running X.
Using rsync

An old favorite for backing up is rsync. One big reason for this is because rsync allows you to only copy those files that have changed since the last backup, so although the initial backup may take a long time, subsequent backups are much faster. It is also highly configurable, can be used with removable media such as USB hard drives or over a network. Here is an example of one way you could use rsync.

First, create an empty file and call it backup.sh:

```bash
matthew@seymour:~$ sudo touch backup.sh
```

Then, using your favorite text editor, enter the following command into the file and save it:

```bash
sudo rsync --force --ignore-errors --delete --delete-excluded --exclude-from=/home/matthew-exclude.txt --backup --backup-dir=`date +%Y-%m-%d` -av / /media/externaldrive/backup/seymour
```

Make the file executable:

```bash
matthew@seymour:~$ sudo chmod +x backup.sh
```

This command uses several options with rsync and puts them in a script that is quick and easy to remember and run. The script can be run at the command line using sudo sh ./backup.sh or as an automated cron job.

Here is a rundown of what is going on in the command. Basically, rsync is told to copy all new and changed files (what to backup) and delete from any existing backup any files that have been deleted on the source (and back them up in a special directory, just to be safe). It is told where to place the backup copy, and is given details on how to deal with specific issues in the process. Read man rsync for more options and to customize to your needs.

Following are the options used here:

- **--force**—Forces deletion of directories in the target location that are deleted in the source, even if the directories in the destination are not empty
- **--ignore-errors**—Tells **--delete** to go ahead and delete files even when there are I/O errors
- **--delete**—Deletes extraneous files from destination directories
- **--delete-excluded**—Also deletes excluded files from destination directories
- **--exclude-from=/home/matt-exclude.txt**—Prevents backing up files or directories listed in this file (it is a simple list with each excluded directory on its own line)
- **--backup**—Creates backups of files before deleting them from a currently existing backup
- **--backup-dir=`date +%Y-%m-%d`**—Creates a backup directory for the previously mentioned files which will look like this: 2010-07-08
- **-av**—Tells rsync to use archive mode and verbose mode
System Rescue

There will come a time when you need to engage in system rescue efforts. This need arises when the system will not even start Linux so that you can recover any files. This problem is most frequently associated with the boot loader program or partition table, but it could be that critical system files have been inadvertently deleted or corrupted. If you have been making backups properly, these kinds of system failures are easily, though not quickly, recoverable through a full restore. Still, valuable current data might not have been backed up since the last scheduled backup, and the backup archives are found to be corrupt, incomplete, or missing. A full restore also takes time you might not have. If the problem causing the system failure is simply a damaged boot loader, a damaged partition table, a missing library, or misconfiguration, a quick fix can get the system up and running and the data can then be easily retrieved.

In this section, we will give you a couple quick things you can try when your system fails to boot to restore a broken boot loader or recover your data.

The Ubuntu Rescue Disc

The Ubuntu installation DVD works quite well as a live DVD. To use it, insert the disc and reboot the computer, booting from the DVD just as you did when you installed Ubuntu originally and ran it from the DVD.

Restoring the GRUB2 Boot Loader

The easiest way to restore a broken system’s GRUB2 files is simply to replace them. This will only work with Ubuntu 9.10 or later and only if the system uses GRUB2 (which it will if it was originally installed using 9.10 or later, but might not if Ubuntu was originally
installed using an older Ubuntu release and upgraded as GRUB2 is not automatically installed during release upgrades).

To get started, boot using the live DVD and open a terminal from the menu at Applications, Accessories, Terminal. Then you need to determine which of the hard drive’s partitions holds the Ubuntu installation, which you can discover using

```
matthew@seymour:~$ sudo fdisk -l
```

Unless you customized your installation, in which case you probably already know your partitioning scheme and the location of your Ubuntu installation, the partition will probably be on a drive called sda on the first partition, which you can mount now using

```
matthew@seymour:~$ sudo mount /dev/sda1 /mnt
```

This will mount the drive in the current filesystem (running from the live DVD) at /mnt, where it will be accessible to you for reading and modifying as needed. Next, you will reinstall GRUB2 on this device:

```
matthew@seymour:~$ sudo grub-install --root-directory=/mnt/ /dev/sda
```

At this point, you should reboot (using your hard drive and not the live DVD) and all should be well. After the reboot is complete, enter

```
matthew@seymour:~$ sudo update-grub
```

This will refresh the GRUB2 menu and complete the restoration. A lot of great information about GRUB2 is available at https://help.ubuntu.com/community/Grub2.

### Saving Files from a Non-Booting Hard Drive

If restoring the GRUB2 boot loader fails and you are still unable to boot from the hard drive, you can try to use the live DVD to recover your data. Boot and mount the hard drive as shown previously, then attach an external storage device such as a USB thumb drive or an external hard drive. Then, copy the files you want to save from the mounted drive to the external drive.

If you are unable to mount the drive at all, your options become more limited and possibly more expensive. It is likely that either the hardware has failed or the file system has become badly corrupted. In either case, recovery is either impossible or more difficult and best left to experts if the data is important to you. But, the good news is that you have been making regular backups, right? So, you probably only lost a day or maybe a week of work and can buy a new drive, install it, and start from scratch, putting the data from your backup on your new Ubuntu installation on the new hardware.

Every experienced system administrator has had this happen because no hardware is infallible. We expect occasional hardware failures and that’s why we have good backup and recovery schemes in place for data. There are two types of sysadmins: those who lose data when this happens and those who have good schemes in place. Be forewarned and be wise.

If you didn’t have a backup, which happens to most sysadmins only once in their lives because they learn from the mistake, stop messing with the hard drive immediately. Your best bet to recover the data will be very expensive, but you should look for a company that specializes in the task and pay them to do it. If your data is not worth the expense for recovery and you want to try to recover it yourself, you can try, but this isn’t a task for the
faint of heart and more often than not, the data is simply lost. Again, the moral of the story is backup regularly, check your backups to be sure they are valid, and repeat. Practice restoring from backups before you need to do it, perhaps with a test system that is not vital and won’t hurt anything if you make a mistake.

One of the benefits of open source technology in general and Linux in particular is that it can be used effortlessly across several networking environments as well as the Internet. With strong support for the standard Internet protocol TCP/IP, Linux can talk to all the UNIX flavors, including Mac OS X, Windows (with the help of Samba), NetWare (IPX), and even older protocols such as DECNET and Banyan Vines. Many organizations use Linux as an Internet gateway, allowing many different clients to access the Internet through Linux, as well as communicate via email and instant messaging. Most important is its built-in support for IPv6, which should start to see a significant uptake very soon. It’s safe to say that whatever networking protocol you’ll come across, Linux will be able to work with it in some way.

This chapter covers network and Internet connectivity, as most networks invariably end up connected to the Internet in some shape or form. You will learn about how to get the basics right, including configuration and management of network cards (NICs) and other network services with Ubuntu. You will also find out how to manage network services from the command line—again an important lesson in case you are ever confined to a command prompt. We will also look at connectivity options, both for inbound and outbound network traffic and the importance of PPP (Point to Point Protocol).

We will focus on the use of text interfaces and manual configurations in this chapter. We also include an overview of basic graphical network management in Ubuntu, which is becoming more and more popular. The GUI option has become much more stable, useful and easy-to-comprehend,
to the point that this will be the way most desktop users now interact with networking. However, this is a book for power users who want to learn about the guts of their system, so let’s roll up our sleeves and prepare to get our hands dirty.

Laying the Foundation: The localhost Interface

The first thing that needs to be in place before you can successfully connect to a network or even to the Internet is a localhost interface, sometimes called a loopback interface, but more commonly referenced as lo. The TCP/IP protocol (see “Networking with TCP/IP” later on in this chapter) uses this interface to assign an IP address to your computer and is needed for Ubuntu to establish a PPP interface.

Checking for the Availability of the Loopback Interface

You should not normally have to manually create a loopback interface because Ubuntu creates one automatically for you during installation. To check that one is set up, you can use the ifconfig command, which will list all networking interfaces available, including the lo interface if it exists, like this:

```
matthew@seymour:~$ ifconfig
```

```
lo       Link encap:Local Loopback
         inet addr:127.0.0.1  Mask:255.0.0.0
         inet6 addr: ::1/128 Scope:Host
         UP LOOPBACK RUNNING  MTU:16436  Metric:1
         RX packets:270 errors:0 dropped:0 overruns:0 frame:0
         TX packets:270 errors:0 dropped:0 overruns:0 carrier:0
         collisions:0 txqueuelen:0
         RX bytes:20748 (20.7 KB)  TX bytes:20748 (20.7 KB)
```

What you see in this example is evidence that the loopback interface is present and active. The inet addr is the IP number assigned to the localhost, typically 127.0.0.1 along with the broadcast mask of 255.0.0.0 and that there has been little activity on this interface (RX = receive and TX = transmit). If your output does not look like the one shown previously, you must hand-configure the localhost interface after you finish the rest of this section. You can also see the Ipv6 address that is assigned to lo, which is ::1/128, referred to as the inet6 addr.

Configuring the Loopback Interface Manually

The localhost interface’s IP address is specified in a text configuration file that is used by Ubuntu to keep record of various network wide IP addresses. The file is called /etc/hosts and usually exists on a system, even if it is empty. The file is used by the Linux kernel and other networking tools to enable them to access local IP addresses and hostnames. If you have not configured any other networking interfaces then you may find that the file looks something like this:

```
127.0.0.1 localhost
```

Download from www.eBookTM.com
Laying the Foundation: The localhost Interface

127.0.0.1    localhost
127.0.1.1    seymour

# The following lines are desirable for IPv6 capable hosts

::1    localhost ip6-localhost ip6-loopback
fe00::0    ip6-localnet
ff00::0    ip6-mcastprefix
ff02::1    ip6-allnodes
ff02::2    ip6-allrouters
ff02::3    ip6-allhosts

127.0.0.1    localhost

The first line defines the special localhost interface and assigns it an IP address of 127.0.0.1. You might hear or read about terms such as localhost, loopback, and dummy interface; all these terms refer to the use of the IP address 127.0.0.1. The term loopback interface is used to describe how to Linux networking drivers, it looks as though the machine is talking to a network that consists of only one machine; the kernel sends network traffic to and from itself on the same computer. This is sometimes referred to as a "dummy interface" because the interface doesn't really exist; it is not a real address as far as the outside world is concerned; it exists only for the local machine, to trick the kernel into thinking that it and any network aware programs running that require a network interface to operate have one available without them actually being aware that the connection is a connection to the same machine. It is a dummy, not in the sense of stupid or silent, but in the sense that it is a mock up or substitute for something real.

Each networked Ubuntu machine on a LAN will use this same IP address for its localhost. If for some reason you discover that an Ubuntu computer does not have this interface, perhaps because someone well-meaning person deleted it without understanding it was needed, you can edit the /etc/hosts file to add the localhost entry as you saw previously, and then use the ifconfig and route commands using your sudo permissions to create the interface like this:

matthew@seymour:~$ sudo /sbin/ifconfig lo 127.0.0.1
matthew@seymour:~$ sudo /sbin/route add 127.0.0.1 lo

These commands will create the localhost interface in memory (all interfaces, such as eth0 or ppp0, are created in memory when using Linux), and will then add the IP address 127.0.0.1 to an internal (in-memory) table so that the Linux kernel's networking code can keep track of routes to different addresses.
Use the `ifconfig` command as shown previously to test the interface.

You should now be able to use `ping` to check that the interface is responding properly like this (using either `localhost` or its IP address):

```
matthew@seymour:-$ ping -c 3 localhost
PING localhost (127.0.0.1) 56(84) bytes of data.
64 bytes from localhost (127.0.0.1): icmp_seq=1 ttl=64 time=0.154 ms
64 bytes from localhost (127.0.0.1): icmp_seq=2 ttl=64 time=0.159 ms
64 bytes from localhost (127.0.0.1): icmp_seq=3 ttl=64 time=0.153 ms
--- localhost ping statistics ---
3 packets transmitted, 3 received, 0% packet loss, time 1998ms
rtt min/avg/max/mdev = 0.153/0.155/0.159/0.010 ms
```

The `-c` option is used to set the number of pings, and the command, if successful (as it was here), returns information regarding the round-trip speed of sending a test packet to the specified host.

The second line in the `/etc/hosts` file uses the actual hostname of the computer and assigns it to a similar private IP address that is unique to that computer. In the earlier code example, you can see that `127.0.1.1` is assigned to seymour, which is the computer on which that hosts file resides.

The remaining lines are used for IPv6 and can be ignored with the exception of the line that begins `::1`—this is used to define the localhost connection for IPv6, which you can text with the `ping6` command at the terminal like this:

```
matthew@seymour:-$ ping6 -c 3 ::1
PING ::1 (::1) 56 data bytes
64 bytes from ::1: icmp_seq=1 ttl=64 time=0.102 ms
64 bytes from ::1: icmp_seq=2 ttl=64 time=0.140 ms
64 bytes from ::1: icmp_seq=3 ttl=64 time=0.140 ms
--- ::1 ping statistics ---
2 packets transmitted, 2 received, 0% packet loss, time 134ms
rtt min/avg/max/mdev = 0.140/0.140/0.140/0.000 ms
```
Networking with TCP/IP

The basic building block for any network based on UNIX hosts is the Transport Control Protocol/Internet Protocol (TCP/IP) suite, which includes three protocols even though only two get to be in the abbreviation. The suite consists of the Internet Protocol (IP), Transport Control Protocol (TCP), and Universal Datagram Protocol (UDP). IP is the base protocol. The TCP/IP suite is packet-based, which means that data is broken into little chunks on the transmit end for transmission to the receiving end. Breaking data up into manageable packets allows for faster and more accurate transfers. In TCP/IP, all data travels via IP packets, which is why addresses are referred to as IP addresses. It is the lowest level of the suite.

TCP is also a connection-based protocol. Before data is transmitted between two machines, a connection is established between them. When a connection is made, a stream of data is sent to the IP to be broken into the packets that are then transmitted. At the receiving end, the packets are put back in order and sent to the proper application port. TCP/IP forms the basis of the Internet; without it the Internet would be a very different place indeed, if it even existed!

On the other hand, UDP is a connectionless protocol. Applications using this protocol just choose their destination and start sending. UDP is normally used for small amounts of data or on fast and reliable networks. If you are interested in the internals of TCP/IP, see the “Reference” section at the end of this chapter for places to look for more information.

UBUNTU AND NETWORKING

Chances are that your network card was configured during the installation of Ubuntu. You can use the ifconfig command or Ubuntu’s graphical network configuration tools to edit your system’s network device information or to add or remove network devices on your system. Hundreds of networking commands and utilities are included with Ubuntu—far too many to cover in this chapter and more than enough for coverage in two or three volumes.

Nearly all ethernet cards can be used with Linux, along with many PCMCIA wired and wireless network cards. The great news is that many USB wireless networking devices also work just fine with Linux, and more are supported with each new version of the Linux kernel. You can check the Linux USB Project at www.linux-usb.org/ for the latest developments or to verify support for your device.
After reading this chapter, you might want to learn more about other graphical network clients for use with Linux. The GNOME ethereal client (more at www.ethereal.com/), for example, can be used to monitor all traffic on your LAN or specific types of traffic. Another client, Nmap, can be used to scan a specific host for open ports and other running services (more at http://nmap.org/).

TCP/IP Addressing

To understand networking with Linux, you need to know the basics of TCP/IP addressing. Internet IP addresses (also known as public IP addresses) are different from those used internally on a local area network, or LAN. Internet IP addresses are assigned (for the United States and some other hosts) by the American Registry for Internet Numbers, available at www.arin.net/. Entities that need an Internet address apply to this agency to be assigned an address. The agency assigns Internet service providers (ISPs) one or more blocks of IP addresses, which the ISPs can then assign to their subscribers.

You will quickly recognize the current form of TCP/IP addressing, known as IPv4 (IP Version 4). In this method, a TCP/IP address is expressed of a series of four decimal numbers—a 32-bit value expressed in a format known as dotted decimal format, such as 192.168.0.1. Each set of numbers is known as an octet (eight ones and zeros, such as 10000000 to represent 128) and ranges from zero to 255.

The first octet usually determines what class the network belongs to. There are three classes of networks:

- **Class A**—Consists of networks with the first octet ranging from 1 to 126. There are only 126 Class A networks—each composed of up to 16,777,214 hosts. (If you are doing the math, there are potentially 16,777,216 addresses, but no host portion of an address can be all zeros or 255s.) The “10.” network is reserved for local network use, and the “127.” network is reserved for the loopback address of 127.0.0.1. Loopback addressing is used by TCP/IP to enable Linux network-related client and server programs to communicate on the same host. This address will not appear and is not accessible on your LAN.

  **NOTE**  
  Notice that zero is not included in Class A. The zero address is used for network-to-network broadcasts. Also, note that there are two other classes of networks, Classes D and E. Class D networks are reserved for multicast addresses and not for use by network hosts. Class E addresses are deemed experimental, and thus are not open for public addressing.

- **Class B**—Consists of networks defined by the first two octets with the first ranging from 128 to 191. The “128.” network is also reserved for local network use. There are 16,382 Class B networks—each with 65,534 possible hosts.
- **Class C**—Consists of a network defined by the first three octets with the first ranging from 192 to 223. The “192.” network is another that is reserved for local network use. There are a possible 2,097,150 Class C networks of up to 254 hosts each.

No host portion of an IP address can be all zeros or 255s. These addresses are reserved for broadcast addresses. IP addresses with all zeros in the host portion are reserved for network-to-network broadcast addresses. IP addresses with all 255s in the host portion are reserved for local network broadcasts. Broadcast messages are not typically seen by users.

These classes are the standard, but a *netmask* also determines what class your network is in. The netmask determines what part of an IP address represents the network and what part represents the host. Common netmasks for the different classes are:

- **Class A**—255.0.0.0
- **Class B**—255.255.0.0
- **Class C**—255.255.255.0

Because of the allocation of IP addresses for Internet hosts, it is now impossible to get a Class A network. It is also nearly impossible to get a Class B network (all the addresses have been given out, but some companies are said to be willing to sell theirs), and Class C network availability is dropping rapidly with the continued growth of Internet use worldwide.

---

**LIMITS OF CURRENT IP ADDRESSING**

The current IPv4 address scheme is based on 32-bit numbering and limits the number of available IP addresses to about 4.1 billion. Many companies and organizations (particularly in the United States) were assigned very large blocks of IP addresses in the early stages of the growth of the Internet, which has left a shortage of “open” addresses. Even with careful allocation of Internet-connected host IP addresses and the use of network address translation (NAT) to provide communication to and from machines behind an Internet-connected computer, the Internet might run out of available addresses.

To solve this problem, a newer scheme named IPv6 (IP version 6) is being implemented. It uses a much larger addressing solution that is based on 128-bit addresses, with enough room to include much more information about a specific host or device, such as global positioning server (GPS) or serial numbering. Although the specific details about the entire contents of the an IPv6 address have yet to be finalized, all Internet-related organizations appear to agree that something must be done to provide more addresses.

You can get a good overview of the differences between IPv4 and IPv6 policies regarding IP address assignments, and the registration process of obtaining IP addresses at https://www.arin.net/knowledge/v4-v6.html and https://www.arin.net/resources/request.html.

Ubuntu supports the use of IPv6 and includes a number of networking tools conforming to IPv6 addressing.
Migration to IPv6 is slow in coming, however, because the majority of computer operating systems, software, hardware, firmware, and users are still in the IPv4 mindset. Supporting IPv6 requires rewriting many networking utilities, portions of operating systems currently in use, and firmware in routing and firewall hardware.

Using IP Masquerading in Ubuntu

Three blocks of IP addresses are reserved for use on internal networks and hosts not directly connected to the Internet. The address ranges are from 10.0.0.0 to 10.255.255.255, or 1 Class A network; from 172.16.0.0 to 172.31.255.255, or 16 Class B networks; and from 192.168.0.0 to 192.168.255.255, or 256 Class C networks. Use these IP addresses when building a LAN for your business or home. Which class you choose can depend on the number of hosts on your network.

Internet access for your internal network can be provided by a PC running Ubuntu or a router. The host or device is connected to the Internet and is used as an Internet gateway to forward information to and from your LAN. The host should also be used as a firewall to protect your network from malicious data and users while functioning as an Internet gateway.

A PC used in this fashion typically has at least two network interfaces. One is connected to the Internet and the other connected to the computers on the LAN (via a hub or switch). Some broadband devices also incorporate four or more switching network interfaces. Data is then passed between the LAN and the Internet using network address translation, or NAT, sometimes known in Linux circles as IP masquerading.

**NOTE**

Do not rely on a single point of protection for your LAN, especially if you use wireless networking, provide dial-in services, or allow mobile (laptop or PDA) users internal or external access to your network. Companies, institutions, and individuals relying on a “moat mentality” have often discovered to their dismay that such an approach to security is easily breached. Make sure that your network operation is accompanied by a security policy that stresses multiple levels of secure access, with protection built into every server and workstation—something easily accomplished when using Linux.

Ports

Most servers on your network have more than one task. For example, web servers often have to serve both standard and secure pages. You might also be running an FTP server on the same host. For this reason, applications are provided ports to use to make “direct” connections for specific software services. These ports help TCP/IP distinguish services so that data can get to the correct application. If you check the file /etc/services, you will see the common ports and their usage. For example, for FTP, HTTP, and Post Office Protocol (email retrieval server), you will see:
<table>
<thead>
<tr>
<th>Service</th>
<th>Port</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>ftp</td>
<td>21/tcp</td>
<td></td>
</tr>
<tr>
<td>http</td>
<td>80/tcp</td>
<td># WorldWideWeb HTTP</td>
</tr>
<tr>
<td>pop3</td>
<td>110/tcp</td>
<td># POP version 3</td>
</tr>
</tbody>
</table>

The ports defined in `/etc/services` in this example are 21 for FTP, 80 for HTTP, and 110 for POP3. Some other common port assignments are 25 for `simple mail transport protocol (SMTP)` and 22 for `secure shell (SSH)` remote login. Note that these ports are not set in stone, and you can set up your server to respond to different ports. For example, although port 22 is listed in `/etc/services` as a common default for SSH, the sshd server can be configured to listen on a different port by editing its configuration file `/etc/ssh/sshd_config`. The default setting (commented out with a pound sign) looks like this:

```
#Port 22
```

Edit the entry to use a different port, making sure to select an unused port number, such as `Port 2224`.

Save your changes, and then restart the sshd server. (Refer to Chapter 11, “Automating Tasks,” to see how to restart a service.) Remote users must now access the host through port 2224, which can be done using ssh’s `-p (port)` option like this:

```
$ ssh -p 2224 remote_host_name_or_IP
```

## Network Organization

Properly organizing your network addressing process grows more difficult as the size of your network grows. Setting up network addressing for a Class C network with fewer than 254 devices is simple. Setting up addressing for a large, worldwide company with a Class A network and many different users can be extremely complex. If your company has fewer than 254 `hosts` (meaning any device that requires an IP address, including computers, printers, routers, switches, and other devices) and all your workgroups can share information, a single Class C network will be sufficient.

### Subnetting

Within Class A and B networks, there can be separate networks called `subnets`. Subnets are considered part of the host portion of an address for network class definitions. For example, in the 128. Class B network, you can have one computer with an address of 128.10.10.10 and another with an address of 128.10.200.20; these computers are on the same network (128.10.), but they have different subnets (128.10.10. and 128.10.200.). Because of this, communication between the two computers requires either a router or a switch. Subnets can be helpful for separating workgroups within your company.

Often subnets can be used to separate workgroups that have no real need to interact with or to shield from other groups’ information passing among members of a specific workgroup. For example, if your company is large enough to have its own HR department and payroll section, you could put those departments’ hosts on their own subnet and use...
your router configuration to limit the hosts that can connect to this subnet. This configuration prevents networked workers who are not members of the designated departments from being able to view some of the confidential information the HR and payroll personnel work with.

Subnet use also enables your network to grow beyond 254 hosts and share IP addresses. With proper routing configuration, users might not even know they are on a different subnet from their co-workers. Another common use for subnetting is with networks that cover a wide geographic area. It is not practical for a company with offices in Chicago and London to have both offices on the same subnet, so using a separate subnet for each office is the best solution.

**Subnet Masks**

Subnet masks are used by TCP/IP to show which part of an IP address is the network portion and which part is the host. Subnet masks are usually referred to as *netmasks*. For a pure Class A network, the netmask would be 255.0.0.0; for a Class B network, the netmask would be 255.255.0.0; and for a Class C network, the netmask would be 255.255.255.0. Netmasks can also be used to deviate from the standard classes.

By using customized netmasks, you can subnet your network to fit your needs. For example, your network has a single Class C address. You have a need to subnet your network. Although this is not possible with a normal Class C subnet mask, you can change the mask to break your network into subnets. By changing the last octet to a number greater than zero, you can break the network into as many subnets as you need.

For more information on how to create customized subnet masks, see Day 6, “The Art of Subnet Masking,” in *Sams Teach Yourself TCP/IP Network Administration in 21 Days*. That chapter goes into great detail on how to create custom netmasks and explains how to create an addressing cheat sheet for hosts on each subnet. The Linux Network Administrator’s Guide also has good information about how to create subnets at www.tldp.org/LDP/nag2/index.html.

**Broadcast, Unicast, and Multicast Addressing**

Information can get to systems through three types of addresses: unicast, multicast, and broadcast. Each type of address is used according to the purpose of the information being sent, as explained here:

- **Unicast**—Sends information to one specific host. Unicast addresses are used for Telnet, FTP, SSH, or any other information that needs to be shared in a one-to-one exchange of information. Although it is possible that any host on the subnet/network can see the information being passed, only one host is the intended recipient and will take action on the information being received.

- **Multicasting**—Broadcasts information to groups of computers sharing an application, such as a video conferencing client or online gaming application. All the machines participating in the conference or game require the same information at precisely the same time to be effective.
Broadcasting—Transmits information to all the hosts on a network or subnet. Dynamic Host Configuration Protocol (DHCP) uses broadcast messages when the DHCP client looks for a DHCP server to get its network settings, and Reverse Address Resolution Protocol (RARP) uses broadcast messages for hardware address to IP address resolution. Broadcast messages use .255 in all the host octets of the network IP address. (10.2.255.255 will broadcast to every host in your Class B network.)

Hardware Devices for Networking

As stated at the beginning of this chapter, networking is one of the strong points of the Linux operating system. This section covers the classes of devices used for basic networking. Note that this section talks about hardware devices, and not Linux networking devices, which are discussed in the section, “Using Network Configuration Tools.”

Network Interface Cards

A computer must have a network interface card (NIC) to connect to a network. Currently, there are several topologies (ways of connecting computers) for network connections. These topologies range from the old and mostly outdated 10BASE-2 to the much newer and popular wireless Wi-Fi or 802.11 networking.

Each NIC has a unique address (the hardware address, known as media access control, or MAC), which identifies that NIC. This address is six pairs of hexadecimal bits separated by colons (:). A MAC address looks similar to this: 00:60:08:8F:5A:D9. The hardware address is used by DHCP (see “Dynamic Host Configuration Protocol” later in this chapter) to identify a specific host. It is also used by the Address Resolution Protocol (ARP) and Reverse Address Resolution Protocol (RARP) to map hosts to IP addresses.

This section covers some of the different types of NIC used to connect to your network.

Token Ring

Token ring networking was developed by IBM. As the name implies, the network is set up in a ring. A single “token” is passed from host to host, indicating the receiving host’s permission to transmit data.

Token ring has a maximum transfer rate of 16Mbps (16 million bits per second). Unlike 10BASE-2 and 10BASE-5, token ring uses what is called unshielded twisted pair (UTP) cable. This cable looks a lot like the cable that connects your phone to the wall. Almost all token ring NICs are recognized by Linux.

10BASE-T

10BASE-T was the standard for a long time. A large number of networks still use it. 10BASE-T also uses UTP cable. Instead of being configured in a ring, 10BASE-T mostly uses a star architecture. In this architecture, the hosts all connect to a central location (usually a hub, which you learn about later in the section titled “Hubs and Switches”). All the data is sent to all hosts, but only the destination host takes action on individual packets. 10BASE-T has a transfer rate of 10Mbps.
10BASE-T has a maximum segment length of 100 meters. There are many manufacturers of 10BASE-T NICs, and most are recognized by Ubuntu.

**100BASE-T**

100BASE-T was popular around the turn of the millennium, keeping the same ease of administration as 10BASE-T while increasing the speed by a factor of 10. For most networks, the step from 10BASE-T to 100BASE-T is as simple as replacing NICs and hubs. Most 100BASE-T NICs and hubs can also handle 10BASE-T and can automatically detect which is in use. This allows for a gradual network upgrade and usually does not require rewiring your whole network. Nearly every known 100BASE-T NIC and most generic NICs are compatible with Linux. 100BASE-T requires category 5 unshielded twisted pair cabling.

**1000BASE-T**

1000BASE-T—usually referred to as *gigabit ethernet*—is the accepted standard in enterprise networking, with most NICs being detected and configured correctly by Ubuntu. Like 100BASE-T NICs, gigabit NICs automatically downgrade if they are plugged in to a slower network. Also like 100BASE-T, gigabit NICs require category 5 unshielded twisted pair cabling; however, many institutions are now deploying category 6 cables because they have much longer range and so are often worth the extra cost. You will find that most newer computers are sold with gigabit NICs.

**Fiber Optic and Gigabit Ethernet**

Fiber optic is more commonly used in newer and high-end installations because the cost of upgrading can be prohibitive for older sites.

Fiber optics were originally used on *fiber distributed data interface (FDDI)* networks, similar to token ring in structure except that there are two rings—one is primary and the other is secondary. The primary ring is used exclusively, and the secondary sits idle until there is a break in the primary ring. That is when the secondary ring takes over, keeping the network alive. FDDI has a speed of 100Mbps and has a maximum ring length of 62 miles. FDDI uses several tokens at the same time that, along with the faster speed of fiber optics, account for the drastic increase in network speed.

As stated, switching to a fiber optic network can be very costly. To make the upgrade, the whole network has to be rewired, and all NICs must be replaced at the same time. Most FDDI NICs are recognized by Linux.

Fiber-related gigabit is termed 1000BASE-X, whereas 1000BASE-T gigabit ethernet uses twisted-pair (see the “Unshielded Twisted Pair” section, later in this chapter).

**Wireless Network Interfaces**

Wireless networking, as the name states, works without network cables and is an extremely popular option, particularly for those whose spouses do not like wires trailing everywhere! Upgrading is as easy as replacing network cards and equipment, such as routers and switches. Wireless networking equipment can also work along with the traditional wired networking using existing equipment.

It might not be practical to upgrade a desktop or large server to wireless just yet if the wiring is already in place. Wireless networking is still generally slower than a traditional
wired network. However, this situation is changing with wider adoption of newer protocols, such as 802.11n (alongside the older 802.11b and the still current and common 802.11g), along with the introduction of more compliant and inexpensive wireless NICs. Some 802.11g NICs work at up to 108Mbps, which appears faster than 100BASE-T wired networking on the surface. However, in practice, it is a great deal slower: Unless your networking environment has paper-thin walls, you can usually halve the reported speed of Wi-Fi network devices, so 108Mbps works about to be about half the speed of 100BASE-T. The newer 802.11n promises to be up to seven times faster than 802.11g, but adoption of and standardization within implementations of 802.11n is going slowly.

With each new Linux kernel release, more and more wireless NICs are compatible. That said, it is usually better to get brand name wireless NICs, because you have a better chance of compatibility. Wireless networking is discussed more later in this chapter.

**Network Cable**

Currently, three types of network cable exist: coaxial, unshielded twisted pair (UTP), and fiber. Coaxial cable (rarely used today) looks a lot like the coaxial cable used to connect your television to the cable jack or antenna. UTP looks a lot like the cable that runs from your phone to the wall jack (the jacks are a bit wider). Fiber cable looks sort of like the RCA cables used on your stereo or like the cable used on your electrical appliances in your house (two separate segments connected together). The following sections discuss UTP and fiber network cable in more detail.

**Unshielded Twisted Pair**

Unshielded twisted pair (UTP) uses color-coded pairs of thin copper wire to transmit data. Six categories of UTP exist—each serving a different purpose:

- **Category 1 (Cat1)**—Used for voice transmissions such as your phone. Only one pair is used per line—one wire to transmit and one to receive. An RJ-11 plug is used to connect the cable to your phone and the wall.

- **Category 2 (Cat2)**—Used in early token ring networks. Has a transmission rate of 4Mbps (million bits per second) and has the slowest data transfer rate. An RJ-11 plug is also used for cable connections.

- **Category 3 (Cat3)**—Used for 10BASE-T networks. It has a transmission rate of 10Mbps. Three pairs of cables are used to send and receive signals. RJ-11 or RJ-45 plugs can be used for Cat3 cables, usually deferring to the smaller RJ-11. RJ-45 plugs are similar in design to RJ-11, but are larger to handle up to four pairs of wire and are used more commonly on Cat5 cables.

- **Category 4 (Cat4)**—Used in modern token ring networks. It has a transmission rate of 16Mbps and is less and less common because companies are switching to better alternatives. RJ-45 plugs are used for cable connections.

- **Category 5 (Cat5)**—The fastest of the UTP categories with a transmission rate of up to 1000Mbps. It is used in both 100BASE-T and 1000BASE-T networks and uses four pairs of wire. Cat5 cable came out just as 10BASE-T networks were becoming popular.
and isn’t much more expensive than Cat3 cable. As a result, most 10BASE-T networks use Cat5 UTP instead of Cat3. Cat5 cable uses RJ-45 plugs.

- **Category 6 (Cat6)**—Also rated at 1000Mbps, this cable is available in two forms: stranded for short runs (25-meter) and solid for up to 100-meter runs, but which should not be flexed.

**Fiber Optic Cable**
Fiber optic cable (fiber) is usually orange or red in color. The transmission rate is 100Mbps and has a maximum length of 62 miles. Fiber uses a two-pronged plug to connect to devices. A couple of advantages to fiber are that because it uses light instead of electricity to transmit its signal, it is free from the possibility of electromagnetic interference and is also more difficult to tap into and eavesdrop.

**Hubs and Switches**
Hubs and switches are used to connect several hosts together on a star architecture network. They can have any number of connections; the common sizes are 4, 8, 16, 24, and 48 connections (ports)—each port has a light that comes on when a network connection is made (link light). Their use enables you to expand your network easily; you can just add new hubs or switches when you need to add new connections. Each unit can connect to the other hubs or switches on the network, typically, through a port on the hub or switch called an **uplink** port. This enables two hubs or switches, connected by their uplink ports, to act as one hub or switch. Having a central location where all the hosts on your network can connect allows for easier troubleshooting of problems. If one host goes down, none of the other hosts are affected (depending on the purpose of the downed host). Because hubs and switches are not directly involved with the Linux operating system, compatibility is not an issue.

If you are constructing a small to mid-size network, it is important to consider whether you intend to use either hubs or switches. Hubs and switches are visually the same in that they have rows of network ports. However, under the hood, the difference is quite important. Data is sent as packets of information across the network; with a hub the data is transmitted simultaneously to all the network ports, irrespective of which port the destination computer is attached to.

Switches, however, are more intelligent because they can direct packets of information to the correct network port that leads to the destination computer. They do this by “learning” the MAC addresses of each computer that is attached to them. In short, using switches minimizes excess packets being sent across the network, thus increasing network bandwidth available. In a small network with a handful of computers, the use of hubs might be perfectly acceptable and you will find that hubs are generally cheaper than switches. However, for larger networks of 15 computers or more, you should consider implementing a switched network.
Troubleshooting network connections can be a challenge, especially on large networks. If a user complains that he has lost his network connection, the hub or switch is a good place to start. If the link light for the user's port is lit, chances are the problem is with the user's network configuration. If the link light is not on, the host's NIC is bad, the cable is not inserted properly, or the cable has gone bad for some reason.

Routers and Bridges

Routers and bridges are used to connect different networks to your network and to connect different subnets within your network. Routers and bridges both serve the same purpose of connecting networks and subnets, but they do so with different techniques. The information in the following sections will help you choose the connection method that best suits your needs.

Bridges

Bridges are used within a network to connect different subnets. A bridge blindly relays all information from one subnet to another without any filtering and is often referred to as a *dumb gateway*. This can be helpful if one subnet in your network is becoming overburdened and you need to lighten the load. A bridge is not very good for connecting to the Internet, however, because it lacks filtering. You really do not want all traffic traveling the Internet to be able to get through to your network.

Routers

Routers can pass data from one network to another, and they allow for filtering of data. Routers are best suited to connect your network to an outside network, such as the Internet. If you have a web server for an internal intranet that you do not want people to access from the Internet, for example, you can use a router's filter to block port 80 from your network. These filters can be used to block specific hosts from accessing the Internet as well. For these reasons, routers are also called *smart gateways*.

Routers range in complexity and price from an enterprise-grade Cisco brand router that can cost thousands of dollars to consumer brands designed for home or small office use that can be less than a hundred dollars.

Initializing New Network Hardware

All the initial network configuration and hardware initialization for Ubuntu is normally done during installation. At times, however, you could have to reconfigure networking on your system, such as when a host needs to be moved to a different subnet or a different network, or if you replace any of your computer’s networking hardware.

Linux creates network interfaces in memory when the kernel recognizes that a NIC or other network device is attached to the system. These interfaces are unlike other Linux interfaces, such as serial communications ports, and do not have a corresponding device.
file in the /dev directory. Unless support for a particular NIC is built in to your kernel, Linux must be told to load a specific kernel module to support your NIC. More than 100 such modules are located in the /lib/modules/2.6.XX-XX/kernel/net directory (where XX-XX is your version of the kernel).

You can initialize a NIC in several ways when using Linux. When you first install Ubuntu, automatic hardware probing detects and configures your system to use any installed NICs. If you remove the original NIC and replace it with a different make and model, your system will not automatically detect and initialize the device unless you configure Ubuntu to use automatic hardware detection when booting. Ubuntu should detect the absence of the old NIC and the presence of the new NIC at boot time.

If you do not use automatic hardware detection and configuration, you can initialize network hardware by:

- Manually editing the /etc/modprobe.conf file to prompt the system to recognize and support the new hardware upon reboot
- Manually loading or unloading the new device’s kernel module with the modprobe command

The following sections explain these methods in greater detail.

**Editing the /etc/modprobe.conf File**

This file may not be present when you first look for it, so you may need to create a blank file in a text editor. You can manually edit the /etc/modprobe.conf file to add a module dependency entry (also known as a directive) to support a new NIC or other network device. This entry includes the device’s name and its corresponding kernel module. After you add this entry, the Linux kernel recognizes your new networking hardware upon reboot. Ubuntu runs a module dependency check upon booting.

For example, if your system uses a RealTek NIC, you could use an entry like this:

```
alias eth0 8139too
```

The example entry tells the Linux kernel to load the 8139too.o kernel module to support the eth0 network device. On the other hand, if you have an Intel Ethernet Pro NIC installed, you would use an entry like this:

```
alias eth0 eepro100
```

Other parameters can be passed to a kernel module using one or more option entries, if need be, to properly configure your NIC. See the modprobe.conf man page for more information on using entries. For more specifics regarding NIC kernel modules, examine the module’s source code because no man pages exist (a good opportunity for anyone willing to write the documentation).

**Using modprobe to Manually Load Kernel Modules**

You do not have to use an /etc/modprobe.conf entry to initialize kernel support for your new network device. As root (using sudo), you can manually load or unload the device’s
Using Network Configuration Tools

If you add or replace networking hardware after your initial installation, you must configure the new hardware. You can do so using either the command line or the graphical configuration tools. To configure a network client host using the command line, you can...
use a combination of commands or edit specific files under the /etc directory. To configure the hardware through a graphical interface, you can use Ubuntu's graphical tool for X called nm-connection-editor, found at System, Preferences, Network Connections. This section introduces command-line and graphical software tools you can use to configure a network interface and network settings on your Ubuntu system. You'll see how to control your NIC and manage how your system interacts with your network.

Using the command-line configuration tools can seem difficult if you are new to Linux. For anyone new to networking, the nm-connection-editor graphical tool is the way to go. Both manual and graphical methods require super user privileges to work. You should not edit any scripts or settings files used by graphical network administration tools on your system. Your changes will be lost the next time the tool is run! Either use a manual approach all the time and write your own network setup script, or stick to using graphical configuration utilities. Don’t switch back and forth between the two methods.

**Command-Line Network Interface Configuration**

You can configure a network interface from the command line using the basic Linux networking utilities. You configure your network client hosts either with commands to change your current settings or by editing a number of system files. Two commands, ifconfig and route, are used for network configuration. The netstat command displays information about the network connections.

**/sbin/ifconfig**

ifconfig is used to configure your network interface. You can use it to:

- Activate or deactivate your NIC or change your NIC’s mode
- Change your machine’s IP address, netmask, or broadcast address
- Create an IP alias to allow more than one IP address on your NIC
- Set a destination address for a point-to-point connection

You can change as many or as few of these options as you’d like with a single command. The basic structure for the command is:

```bash
ifconfig [network device] options
```

Table 14.1 shows a subset of ifconfig options and examples of their uses.

<table>
<thead>
<tr>
<th>Use</th>
<th>Option</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create alias</td>
<td>[network device]</td>
<td>ifconfig eth0:0:_[number]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>10.10.10.10</td>
</tr>
<tr>
<td>Change IP address</td>
<td></td>
<td>ifconfig eth0 10.10.10.12</td>
</tr>
</tbody>
</table>
The `ifconfig` man page shows other options that enable your machine to interface with a number of network types such as AppleTalk, Novell, IPv6, and others. Again, read the man page for details on these network types.

### TABLE 14.1 Continued

<table>

<td>[·]pointopoint [address]</td>
<td><code>ifconfig point-to-point address 10.10.10.20</code></td>
</tr>
<tr>
<td></td>
<td>`eth0_pointopoint</td>
<td><code>[ifconfig eth0 pointopoint_10.10.10.20]</code></td>
</tr>
</tbody>
</table>

The `ifconfig` man page shows other options that enable your machine to interface with a number of network types such as AppleTalk, Novell, IPv6, and others. Again, read the man page for details on these network types.

**NOTE**

Promiscuous mode causes the NIC to receive all packets on the network. It is often used to sniff a network. Multicasting mode enables the NIC to receive all multicast traffic on the network.

If no argument is given, `ifconfig` displays the status of active interfaces. For example, the output of `ifconfig`, without arguments and one active and configured NIC, looks similar to this:

```
matthew@seymour:~$ ifconfig
eth0      Link encap:Ethernet  HWaddr 00:90:f5:8e:52:b5
          UP BROADCAST MULTICAST  MTU:1500  Metric:1
          RX packets:0 errors:0 dropped:0 overruns:0 frame:0
          TX packets:0 errors:0 dropped:0 overruns:0 carrier:0
```
The output is easily understood. The `inet` entry displays the IP address for the interface. `UP` signifies that the interface is ready for use, `BROADCAST` denotes that the interface is connected to a network that supports broadcast messaging (`ethernet`), `RUNNING` means that the interface is operating, and `LOOPBACK` shows which device (`lo`) is the loopback address. The `maximum transmission unit (MTU)` on `eth0` is 1500 bytes. This determines the size of the largest packet that can be transmitted over this interface (and is sometimes “tuned” to other values for performance enhancement). `Metric` is a number from 0 to 3 that relates to how much information from the interface is placed in the routing table. The lower the number, the smaller the amount of information.

The `ifconfig` command can be used to display information about or control a specific interface using commands that are listed in Table 14.1. For example, to deactivate the first Ethernet device on a host, use the `ifconfig` command, the interface name, and the command `down` like this:

```
matthew@seymour:~$ sudo ifconfig eth0 down
```

You can also configure and activate the device by specifying a hostname or IP address and network information. For example to configure and activate (“bring up”) the `eth0` interface with a specific IP address, use the `ifconfig` command like this:

```
matthew@seymour:~$ sudo ifconfig eth0 192.168.2.9 netmask 255.255.255.0 up
```

If you have a host defined in your system’s `/etc/hosts` file (see the section “Network Configuration Files” later in this chapter), you can configure and activate the interface according to the defined hostname like this:

```
matthew@seymour:~$ sudo ifconfig eth0 dogdog.hudson.com up
```

Read the next section to see how to configure your system to work with your LAN.
The second command used to configure your network is the `route` command. `route` is used to build the routing tables (in memory) implemented for routing packets as well as displaying the routing information. It is used after `ifconfig` has initialized the interface. `route` is normally used to set up static routes to other networks via the gateway or to other hosts. The command configuration is like this:

```
route [options] [commands] [parameters]
```

To display the routing table, use the `route` command with no options. The display will look similar to this:

```
matthew@seymour:~$ route
Kernel IP routing table
    Destination  Gateway  Genmask  Flags  Metric  Ref  Use  Iface
192.168.1.0   *         255.255.255.0  U     2   0   0  wlan0
link-local    *         255.255.0.0  U    1000 0   0  wlan0
default       WirelessAccessPt  0.0.0.0 UG     0   0   0  wlan0
```

In the first column, `Destination` is the IP address (or, if the host is in `/etc/hosts` or `/etc/networks`, the hostname) of the receiving host. The default entry is the default gateway for this machine. The `Gateway` column lists the gateway that the packets must go through to reach their destination. An asterisk (*) means that packets go directly to the host. `Genmask` is the netmask. The `Flags` column can have several possible entries. In our example, `U` verifies that the route is enabled and `G` specifies that `Destination` requires the use of a gateway. The `Metric` column displays the distance to the `Destination`. Some daemons use this to figure the easiest route to the `Destination`. The `Ref` column is used by some UNIX flavors to convey the references to the route. It isn't used by Linux. The `Use` column indicates the number of times this entry has been looked up. Finally, the `Iface` column is the name of the interface for the corresponding entry.

Using the `-n` option to the `route` command will give the same information, substituting IP addresses for names and asterisks (*), and looks like this:

```
matthew@seymour:~$ /sbin/route -n
Kernel IP routing table
    Destination  Gateway  Genmask  Flags  Metric  Ref  Use  Iface
192.168.1.0   0.0.0.0   255.255.255.0  U     2   0   0  wlan0
link-local    0.0.0.0   255.255.0.0  U    1000 0   0  wlan0
0.0.0.0       192.168.1.0 0.0.0.0 UG     0   0   0  wlan0
```

The `route` command can add to the table using the add option. With the add option, you can specify a host (`-host`) or a network (`-net`) as the destination. If no option is used, the `route` command assumes that you are configuring the host issuing the command. The most common uses for the `route` command are to add the default gateway for a host, for a host that has lost its routing table, or if the gateway address has changed. For example, to add a gateway with a specific IP address, you could use the following:

```
matthew@seymour:~$ sudo route add default gw 149.112.50.65
```

Note that you could use a hostname instead of an IP address if desired. Another common use is to add the network to the routing table right after using the `ifconfig` command to configure the interface. Assuming that the `208.59.243.0` entry from the previous examples was missing, replace it using the following command:

```
matthew@seymour:~$ sudo route add -net 208.59.243.0 netmask 255.255.255.0 dev eth0
```

You also can use route to configure a specific host for a direct (point-to-point) connection. For example, say that you have a home network of two computers. One of the computers has a modem through which it connects to your business network. You typically work at the other computer. You can use the route command to establish a connection through specific hosts using the following command:

```
matthew@seymour:~$ sudo route add -host 198.135.62.25 gw 149.112.50.65
```

The preceding example makes the computer with the modem the gateway for the computer you are using. This type of command line is useful if you have a gateway or firewall connected to the Internet. There are many additional uses for the route command, such as manipulating the default packet size. See the man page for those uses.

```
/bin/netstat
```

The `netstat` command is used to display the status of your network. It has several parameters that can display as much or as little information as you prefer. The services are listed by sockets (application-to-application connections between two computers). You can use `netstat` to display the information in Table 14.2.

<table>
<thead>
<tr>
<th><strong>TABLE 14.2</strong> netstat Options</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Option</strong></td>
<td><strong>Output</strong></td>
</tr>
<tr>
<td><code>-g</code></td>
<td>Displays the multicast groups configured</td>
</tr>
<tr>
<td><code>-i</code></td>
<td>Displays the interfaces configured by ifconfig</td>
</tr>
<tr>
<td><code>-s</code></td>
<td>Lists a summary of activity for each protocol</td>
</tr>
<tr>
<td><code>-v</code></td>
<td>Gives verbose output, listing both active and inactive sockets</td>
</tr>
<tr>
<td><code>-c</code></td>
<td>Updates output every second (good for testing and troubleshooting)</td>
</tr>
<tr>
<td><code>-e</code></td>
<td>Gives verbose output for active connections only</td>
</tr>
<tr>
<td><code>-C</code></td>
<td>Displays information from the route cache and is good for looking at past connections</td>
</tr>
</tbody>
</table>
Several other options are available for this command, but they are used less often. As with the `route` command, the man page can give you details about all options and parameters.

**Network Configuration Files**

As previously stated, five network configuration files can be modified to make changes to basic network interaction of your system:

- `/etc/hosts`—A listing of addresses, hostnames, and aliases
- `/etc/services`—Network service and port connections
- `/etc/nsswitch.conf`—Linux network information service configuration
- `/etc/resolv.conf`—Domain name service domain (search) settings
- `/etc/host.conf`—Network information search order (by default, `/etc/hosts` and then DNS)

After these files are modified, the changes are active. As with most configuration files, comments can be added with a hash mark (`#`) preceding the comment. All these files have a man page written about them for more information.

**Adding Hosts to `/etc/hosts`**

The `/etc/hosts` file is a map of IP to hostnames. If you are not using DNS or another naming service, and you are connected to a large network, this file can get quite large and can be a real headache to manage. A small `/etc/hosts` file can look something like this:

```
127.0.0.1       localhost
127.0.1.1       optimus

# The following lines are desirable for IPv6 capable hosts
::1     ip6-localhost ip6-loopback
fe00::0 ip6-localnet
ff00::0 ip6-mcastprefix
ff02::1 ip6-allnodes
ff02::2 ip6-allrouters
ff02::3 ip6-allhosts
```
The first entry is for the loopback entry. The second is for the name of the machine. If no naming service is in use on the network, the only host that myhost will recognize by name is yourhost. (IP addresses on the network can still be used.)

**Service Settings in /etc/services**

The /etc/services file maps port numbers to services. The first few lines look similar to this (the /etc/services file can be quite long, more than 500 lines):

```plaintext
# Each line describes one service, and is of the form:
#
# service-name port/protocol [aliases ...] [# comment]

tcpmux       1/tcp    # TCP port service multiplexer
tcpmux       1/udp    # TCP port service multiplexer
rje          5/tcp    # Remote Job Entry
rje          5/udp    # Remote Job Entry
echo         7/tcp
echo         7/udp
discard      9/tcp      sink null
discard      9/udp      sink null
systat       11/tcp     users
```

Typically, there are two entries for each service because most services can use either TCP or UDP for their transmissions. Usually after /etc/services is initially configured, you will not need to change it.

**Using /etc/nsswitch.conf After Changing Naming Services**

This file was initially developed by Sun Microsystems to specify the order in which services are accessed on the system. A number of services are listed in the /etc/nsswitch.conf file, but the most commonly modified entry is the hosts entry. A portion of the file can look like this:

```plaintext
passwd: compat
group: compat
shadow: compat

hosts: files dns mdns
networks: files

protocols: db files
services: db files
ethers: db files
rpc: db files

netgroup: nis
```
This tells services that they should consult standard UNIX/Linux files for passwd, shadow, and group (/etc/passwd, /etc/shadow, /etc/group, respectively) lookups. For host lookups, the system checks /etc/hosts and if there is no entry, it checks DNS. The commented hosts entry lists the possible values for hosts. Edit this file only if your naming service has changed.

**Setting a Name Server with /etc/resolv.conf**

/etc/resolv.conf is used by DNS, the domain name service. The following is an example of resolv.conf:

```bash
nameserver 192.172.3.8
nameserver 192.172.3.9
search mydomain.com
```

This sets the nameservers and the order of domains for DNS to use. The contents of this file will be set automatically if you use Dynamic Host Configuration Protocol, or DHCP (see the section on “Dynamic Host Configuration Protocol” later in this chapter).

**Setting DNS Search Order with /etc/host.conf**

The /etc/host.conf file lists the order in which your machine will search for hostname resolution. The following is the default /etc/host.conf file:

```bash
order hosts, bind
```

In this example, the host checks the /etc/hosts file first and then performs a DNS lookup. A couple more options control how the name service is used. The only reason to modify this file is if you use NIS for your name service or you want one of the optional services. The nospoof option can be a good option for system security. It compares a standard DNS lookup to a reverse lookup (host-to-IP then IP-to-host) and fails if the two don’t match. The drawback is that often when proxy services are used, the lookup fails, so you want to use this with caution.

**Using Graphical Configuration Tools**

Ubuntu has made some big improvements to how desktop users may configure networking using graphical configuration tools. For most people, all you will need to know is contained in Chapter 2, “Post-Installation Configuration,” in the section about Network Manager. For others, you may configure your network connections by right clicking the networking icon on your top panel and choosing “Edit Connections.” from the menu as shown in Figure 14.1. From the Network Connections window that opens, you may select from various types of connections to configure, including Wired, Wireless, Mobile Broadband, VPN and DSL as shown in Figure 14.2. By default, each is set to auto configure.
and most users will never need to change the settings available here. For those who require doing so, choosing the appropriate tab and clicking the “Add” button will give the opportunity to configure and fine tune settings as needed, such as in the wireless connection example in Figure 14.3.

Dynamic Host Configuration Protocol

As its name implies, Dynamic Host Configuration Protocol (DHCP) configures hosts for connection to your network. DHCP allows a network administrator to configure all TCP/IP parameters for each host as he connects to the network after activation of a NIC. These parameters include automatically assigning an IP address to a NIC, setting name server entries in `/etc/resolv.conf`, and configuring default routing and gateway information for a host. This section first describes how to use DHCP to obtain IP address assignment for your NIC, and then how to quickly set up and start a DHCP server using Ubuntu.

**NOTE**

How DHCP Works

DHCP provides persistent storage of network parameters by holding identifying information for each network client that might connect to the network. The three most common pairs of identifying information are:

- **Network subnet/host address**—Used by hosts to connect to the network at will
- **Subnet/hostname**—Enables the specified host to connect to the subnet
- **Subnet/hardware address**—Enables a specific client to connect to the network after getting the hostname from DHCP

DHCP also allocates to client’s temporary or permanent network (IP) addresses. When a temporary assignment, known as a lease, elapses, the client can request to have the lease extended, or, if the address is no longer needed, the client can relinquish the address. For hosts that will be permanently connected to a network with adequate addresses available, DHCP allocates infinite leases.

DHCP offers your network some advantages. First, it shifts responsibility for assigning IP addresses from the network administrator (who can accidentally assign duplicate IP addresses) to the DHCP server. Second, DHCP makes better use of limited IP addresses. If a user is away from the office for whatever reason, the user’s host can release its IP address for use by other hosts.

Like most things in life, DHCP is not perfect. Servers cannot be configured through DHCP alone because DNS does not know what addresses that DHCP assigns to a host. This

FIGURE 14.3  Assign a static IP address to a network interface.
means that DNS lookups are not possible on machines configured through DHCP alone; therefore, services cannot be provided. However, DHCP can make assignments based on DNS entries when using subnet/hostname or subnet/hardware address identifiers.

**NOTE**

The problem of using DHCP to configure servers using registered hostnames is being addressed by Dynamic DNS which, when fully developed, will enable DHCP to register IP addresses with DNS. This will allow you, for example, to register a domain name (such as matthewhelmke.com) and be able to easily access that domain’s web server without needing to use static IP addressing of a specific host. The largest hurdle to overcome is the security implication of enabling each host connecting to the system to update DNS. A few companies, such as www.dyndns.org/, are already offering Dynamic DNS services and have clients for Linux.

### Activating DHCP at Installation and Boot Time

Ubuntu automatically defaults your network interfaces to using DHCP, because it is the simplest way of setting up a network interface. With *dynamic*, or DHCP-assigned IP addressing schemes for your NIC, the broadcast address is set at 255.255.255.255 because dhclient, the DHCP client used for IP configuration, is initially unaware of where the DHCP server is located, so the request must travel every network until a server replies.

The instruction to use DHCP for your NIC can be found under `/etc/network/interfaces`, with a line that says `dhcpcd`.

Other settings specific to obtaining DHCP settings are saved in the file named `dhclient.conf` under the `/etc/dhcp3/dhclient.conf` directory and are documented in the `dhclient.conf` main page. More than 100 options are also documented in the `dhcp-options` main page.

However, using DHCP is not that complicated. If you want to use DHCP and know that there is a server on your network, you can quickly configure your NIC by using the dhclient like this:

```
matthew@seymour:~$ sudo dhclient
```

Internet Systems Consortium DHCP Client V3.1.3
All rights reserved.
For info, please visit https://www.isc.org/software/dhcp/

Listening on LPF/eth0/00:90:f5:8e:52:b5
Sending on   LPF/eth0/00:90:f5:8e:52:b5
Listening on LPF/virbr0/ee:1a:62:7e:e2:a2
Sending on   LPF/virbr0/ee:1a:62:7e:e2:a2
Listening on LPF/wlan0/00:16:ea:d4:58:88
Sending on   LPF/wlan0/00:16:ea:d4:58:88
Sending on   Socket/fallback
DHCPDISCOVER on eth0 to 255.255.255.255 port 67 interval 7
DHCPDISCOVER on wlan0 to 255.255.255.255 port 67 interval 3
DHCPOFFER of 192.168.1.106 from 192.168.1.1
DHCPREQUEST of 192.168.1.106 on wlan0 to 255.255.255.255 port 67
DHCPACK of 192.168.1.106 from 192.168.1.1
bound to 192.168.1.106 — renewal in 35959 seconds.

In this example, the first ethernet device, eth0, has been assigned an IP address of 192.168.1.106 from a DHCP server at 192.168.1.1. The renewal will take place in 35959 seconds, or about 10 hours (cool tip: Google will convert this for you if you search for 35959 seconds in hours).

**DHCP Software Installation and Configuration**

Installation of the DHCP client and server is fairly straightforward, mainly because Ubuntu already includes `dhclient` in a default installation, but also because installing software is easy using `synaptic` or `apt-get`.

**DHCP dhclient**

DHCP is automatically enabled when you install Ubuntu, so you don’t need to worry about having to enable it. The DHCP client, `dhclient`, sends a broadcast message that the DHCP server replies to with networking information for your host. After it has this, you’re done!

You can however, fine-tune how `dhclient` works, and where and how it obtains or looks for DHCP information. You probably will not need to take this additional effort; but if you do, you can create and edit a file named `dhclient.conf`, and save it in the `/etc` directory with your settings.

**CAUTION**

You shouldn’t just go ahead and overwrite your `dhclient.conf` with any old file, because it could lead you to painful networking problems. Instead, copy the file like this:

```
matthew@seymour:~$ sudo cp /etc/dhcp3/dhclient.conf/ etc/dhcp3/dhclient.conf.backup
```

That way, if anything goes wrong, you can then use the backup to restore the original settings by copying it back to its original location in place of the modified file.

A few of the `dhclient.conf` options include:

- `timeout time` — How long to wait before giving up trying (60 seconds is the default)
- `retry time` — How long to wait before retrying (five minutes is the default)
- `select-timeout time` — How long to wait before selecting a DHCP offer (zero seconds is the default)
- `reboot time` — How long to wait before trying to get a previously set IP (10 seconds is the default)
renew date ;—When to renew an IP lease, where date is in the form of <weekday><year>/<month>/<day> <hour>:<minute>:<second>, such as 3 2010/7/7 22:01:01 for Wednesday, July 7, 2010 at 10:01 p.m.

See the dhclient.conf man page for more information on additional settings.

**DHCP Server**

Again, the easiest way to install the DHCP server on your computer is to use either synaptic or apt-get to retrieve the dhcp3-server package. If you are so inclined, you can go to the Internet Software Consortium (ISC) website and download and build the source code yourself (www.isc.org/). However, we recommend you stay with the package in the Ubuntu repositories because it will be very easy to update if there are security updates.

If you decide to install from a source downloaded from the ISC website, the installation is very straightforward. Just unpack your tar file, run ./configure from the root of the source directory, run make, and finally, if there are no errors, run make install. This puts all the files used by the DHCP daemon in the correct places. If you have the disk space, it is best to leave the source files in place until you are sure that DHCP is running correctly; otherwise, you can delete the source tree.

---

**NOTE**

For whichever installation method you choose, be sure that a file called /etc/dhcp3/dhcpd.leases is created. The file can be empty, but it does need to exist for dhcpd to start properly.

---

**Using DHCP to Configure Network Hosts**

Configuring your network with DHCP can look difficult, but is actually easy if your needs are simple. The server configuration can take a bit more work if your network is more complex and depending on how much you want DHCP to do.

Configuring the server takes some thought and a little bit of work. Luckily, the work involves editing only a single configuration file, /etc/dhcp3/dhcpd.conf. To start the server at boot time, use the service, or ntsysv commands.

The /etc/dhcp3/dhcpd.conf file contains all the information needed to run dhcpd. Ubuntu includes a sample dhcpd.conf in /usr/share/doc/dhcp*/dhcpd.conf.sample. The DHCP server source files also contain a sample dhcpd.conf file.

The /etc/dhcp3/dhcpd.conf file can be looked at as a three-part file. The first part contains configurations for DHCP itself. The configurations include:

- **Setting the domain name**—option domain-name "example.org".

- **Setting DNS servers**—option domain-name-servers ns1.example.org, ns2.example.org (IP addresses can be substituted.)

- **Setting the default and maximum lease times**—default-lease-time 3600 and max-lease-time 14400.
Other settings in the first part include whether the server is the primary (authoritative) server and what type of logging DHCP should use. These settings are considered defaults and can be overridden by the subnet and host portion of the configuration in more complex situations.

**NOTE**

The `dhcpd.conf` file requires semicolons (`;`) after each command statement. If your configuration file has errors or runs improperly, check for this.

The next part of the `dhcpd.conf` deals with the different subnets that your DHCP server serves; this section is quite straightforward. Each subnet is defined separately and can look like this:

```conf
subnet 10.5.5.0 netmask 255.255.255.224 {
    range 10.5.5.26 10.5.5.30;
    option domain-name-servers ns1.internal.example.org;
    option domain-name "internal.example.org";
    option routers 10.5.5.1;
    option broadcast-address 10.5.5.31;
    default-lease-time 600;
    max-lease-time 7200;
}
```

This defines the IP addressing for the 10.5.5.0 subnet. It defines the IP address ranging from 10.5.5.26 through 10.5.5.30 to be dynamically assigned to hosts that reside on that subnet. This example shows that any TCP/IP option can be set from the subnet portion of the configuration file. It shows which DNS server the subnet will connect to, which can be good for DNS server load balancing, or which can be used to limit the hosts that can be reached through DNS. It defines the domain name, so you can have more than one domain on your network. It can also change the default and maximum lease time.

If you want your server to ignore a specific subnet, the following entry can be used to accomplish this:

```conf
subnet 10.152.187.0 netmask 255.255.255.0 {
}
```

This defines no options for the 10.152.187.0 subnet; therefore, the DHCP server ignores it.

The last part of your `dhcpd.conf` is for defining hosts. This can be good if you want a computer on your network to have a specific IP address or other information specific to that host. The key to completing the host section is to know the hardware address of the host. As you learned in “Hardware Devices for Networking,” earlier in this chapter, the
hardware address is used to differentiate the host for configuration. Your hardware address can be obtained by using the `ifconfig` command as described previously. The hardware address is on the `eth0` line labeled "Hwaddr".

```
host hopper {
    hardware ethernet 08:00:07:26:c0:a5;
    fixed-address hopper.matthewhelmke.com;
}
```

This example takes the host with the hardware address 08:00:07:26:c0:a5 and does a DNS lookup to assign the IP address for hopper.matthewhelmke.com to the host.

DHCP can also define and configure booting for diskless clients like this:

```
host bumblebee {
    hardware ethernet 0:0:c0:5d:bd:95;
    filename "vmunix.bumblebee";
    server-name "kernigan.matthewhelmke.com";
}
```

The diskless host bumblebee will get its boot information from server kernigan.matthewhelmke.com and use `vmunix.bumblebee` kernel. All other TCP/IP configuration can also be included.

---

**CAUTION**

Remember, only one DHCP server should exist on a local network to avoid problems. Your DHCP might not work correctly on a LAN with hosts running outdated legacy operating systems. Often Windows NT servers will have the Windows DHCP server installed by default. Because there is no configuration file for NT to sort through, that DHCP server configures your host before the Linux server if both machines are on the same LAN. Check your NT servers for this situation and disable DHCP on the NT server; afterward, your other DHCP-enabled hosts should configure correctly. Also, check to make sure that there are no conflicts if you use a cable or DSL modem, wireless access point (WAP), or other intelligent router on your LAN that can provide DHCP.

---

**Other Uses for DHCP**

A whole host of options can be used in `dhcpd.conf`: Entire books are dedicated to DHCP. The most comprehensive book is *The DHCP Handbook*, available at www.dhcp-handbook.com/. You can define NIS domains, configure NETBIOS, set subnet masks, and define time servers, or many other types of servers—to name a few of the DHCP options you can use. The preceding example will get your DHCP server and client up and running.

The DHCP server distribution contains an example of the `dhcpd.conf` file that you can use as a template for your network. The file shows a basic configuration that can get you started with explanations for the options used.
Wireless Networking

Linux has had support for wireless networking since the first standards were developed in the early 1990s. With computers getting smaller and smaller, the uses for wireless networking increased; meanwhile, the transmission speeds are increasing all the time. There are several ways to create a wireless network. The following sections introduce you to several Linux commands you can use to initialize, configure, and manage wireless networking on your Ubuntu system.

Support for Wireless Networking in Ubuntu

The Linux kernel that ships with Ubuntu provides extensive support for wireless networking. Related wireless tools for configuring, managing, or displaying information about a wireless connection include:

- `iwconfig`—Sets the network name, encryption, transmission rate, and other features of a wireless network interface
- `iwlist`—Displays information about a wireless interface, such as rate, power level, or frequency used
- `iwpriv`—Uses `i` to set optional features, such as roaming, of a wireless network interface
- `iwspy`—Shows wireless statistics of a number of nodes

Support varies for wireless devices, but most modern (that is, post-2005) wireless devices should work with Ubuntu. In general, Linux wireless device software (usually in the form of a kernel module) support the creation of an ethernet device that can be managed by traditional interface tools such as `ifconfig`—with wireless features of the device managed by the various wireless software tools.

For example, when a wireless networking device is first recognized and initialized for use, the driver will most likely report a new device:

```
zd1211rw 5-4:1.0: firmware version 4725

zd1211rw 5-4:1.0: zd1211b chip 050d:705c v4810 \ high 00-17-3f AL2230_RF pa0 g—NS

zd1211rw 5-4:1.0: eth2

usbcore: registered new interface driver zd1211rw
```

This output (from the `dmesg` command) shows that the `eth2` device has been reported. If DHCP is in use, the device should automatically join the nearest wireless subnet and be automatically assigned an IP address. If not, the next step is to use a wireless tool such as
iwconfig to set various parameters of the wireless device. The iwconfig command, along with the device name (eth2 in this example), will show the status:

```
matthew@seymour:~$ iwconfig eth2
eth2      IEEE 802.11b/g  ESSID:"SKY35120"  Nickname:"zd1211"
               Mode:Managed  Frequency:2.462 GHz  
Access Point: 00:18:4D:06:8E:2A
         Bit Rate=24 Mb/s
          Encryption key:0EFD-C1AF-5C8D-B2C6-7A89-3790-07A7-AC64-0AB5\
-C36E-D1E9-A230-1DB9-D227-2EB6-D6C8  Security mode:open
          Link Quality=100/100  Signal level=82/100
            Rx invalid nwid:0  Rx invalid crypt:0  Rx invalid frag:0
         Tx excessive retries:0  Invalid misc:0  Missed beacon:0
```

This example shows a 24Mbps connection to a network named SKY35120. To change a parameter, such as the transmission rate, use a command-line option with the iwconfig command like this:

```
matthew@seymour:~$ sudo iwconfig eth0 rate 11M
```

Other options supported by the iwconfig command include essid, used to set the NIC to connect to a specific network by named; mode, used to enable the NIC to automatically retrieve settings from an access point or connect to another wireless host; or freq, to set a frequency to use for communication. Additional options include channel, frag, enc (for encryption), power, and txpower. Details and examples of these options are in the iwconfig manual page.

You can then use the ifconfig command or perhaps a graphical Ubuntu tool to set the device networking parameters, and the interface will work as on a hardwired LAN. One handy output of the iwconfig command is the link quality output, which can be used in shell scripts or other graphical utilities for signal monitoring purposes.

## Advantages of Wireless Networking

Advantages of wireless networking are its mobility and potential range. If you have a large enough antenna network, your network can stretch many miles. This would be an expensive network, but one that would easily break out of the brick and mortar confines of the office.

Wireless networking would also be a great advantage to college campuses to eliminate the need to tear through walls to install cabling because more and more students expect to have a network connection in their dorm rooms. Wireless networking cards are very reasonable in price and can easily be issued to each student as he requires them.

Home networkers can also benefit from wireless networking. For those who cannot do wired network modifications to their homes, wireless networking removes the unsightly wires running along baseboards and ceilings that are required to connect computers in
different rooms. With a wireless home network, you are not even confined to inside the house. Depending on the transmit power of your router, you can sit out in your backyard and watch clouds drifting by as you type away.

Choosing the right types of wireless devices is an important decision. The next sections discuss some of the basic differences between current protocols used for wireless networking.

Choosing from Among Available Wireless Protocols

The Institute of Electrical and Electronics Engineers (IEEE) started to look seriously at wireless networking in 1990. This is when the 802.11 Standard was first introduced by the Wireless Local Area Networks Standards Working Group. The group based the standard roughly around the architecture used in cellular phone networks. The wireless network is controlled by a base station, which can be just a transmitter attached to the network or, more commonly these days, a router.

Larger networks can use more than one base station. Networks with more than one base station are usually referred to as distribution systems. A distribution system can be used to increase coverage area and support roaming of wireless hosts. You can also employ external omnidirectional antennas to increase coverage area, or if required, use point-to-point, or directional antennas to connect distant computers or networks. Right now, the least expensive wireless Linux networks are built using devices (such as access points or NICs) supporting 802.11b, although the faster 802.11g devices tend to get more shelf space. Devices are available marketed as N or Pre-N, meaning that they implement a draft standard, while the IEEE carry on debating the full N standard. Significantly more power throughput and range are promised by hardware that supports N, but this specification has yet to be formally agreed upon and so implementations are not necessarily standard.

An early standard, 802.11a, offers greater transmission rates than 802.11b, and a number of 802.11a wireless NICs are available (some products provide up to 72Mbps, but will not work with 802.11b devices). Wireless networking devices based on 802.11g, which has the speed improvement of 802.11a and is compatible with 802.11b, are very common. Other wireless protocols include Bluetooth, which provides up to 720Kbps data transfers. Bluetooth is intended for short-range device communications (such as for a printer) and supports a typical range of only 10 meters. Bluetooth is unlike IrDA, which requires line-of-sight (devices that are aimed at each other). Bluetooth use conflicts with 802.11 networks because it also uses the 2.4GHz band. You can find out more at www.bluetooth.com/.

The 802.11 standard specifies that wireless devices use a frequency range of 2400–2483.5MHz. This is the standard used in North America and Europe. In Japan, however, wireless networks are limited to a frequency range of 2471MHz–2479MHz because of Japanese regulations. Within these ranges, each network is given up to 79 non-overlapping frequency channels to use. This reduces the chance of two closely located wireless networks using the same channel at the same time. It also allows for channel hopping, which can be used for security.
Beyond the Network and onto the Internet

Ubuntu supports Internet connections and the use of Internet resources in many different ways. You will find a wealth of Internet-related software included with this book’s version of Ubuntu, and you can download hundreds of additional free utilities from a variety of sources. To use them, you must have a working Internet connection.

In this section, you learn how to set up an Internet connection in Ubuntu using a modem and Point-to-Point Protocol (PPP) as well as other connection methods, including Digital Subscriber Line (DSL) and cable modem services. Just a few years ago, getting a dial-up connection working was difficult—hence, an entire chapter of this book was devoted to it. Today, as long as you have a hardware modem, dial-up configuration is simple. The Ubuntu developers and the wider Linux community have made great progress in making connectivity easier.

Although many experienced Linux users continue to use manual scripts to establish their Internet connectivity, new users and experienced system administrators alike will find Ubuntu’s graphical network configuration interface much easier to use. You learn how to use the Internet Connection Wizard in this chapter, as well as how to configure Ubuntu to provide dial-in PPP support. The chapter also describes how to use Roaring Penguin’s DSL utilities for managing connectivity through a cable modem connection.

Common Configuration Information

Although Ubuntu enables great flexibility in configuring Internet connections, that flexibility comes at the price of an increase in complexity. To configure Internet connectivity in Ubuntu, you must know more about the details of the connection process than you can learn from the information typically provided by your Internet service provider (ISP). In this section of the chapter, you learn what to ask about and how to use the information.

Some ISPs are unaware of Linux or unwilling to support its use with their service. Fortunately, that attitude is rapidly changing, and the majority of ISPs offer services using standard protocols that are compatible with Linux, even if they (or their technical support people) aren’t aware that their own ISPs are Linux-friendly. You just need to press a little for the information you require.

If you are one of the few remaining people using a dial-up modem account (referred to in Linux as PPP for the Point-to-Point Protocol it uses), your ISP will provide your computer with a static or dynamic IP (Internet Protocol) address. A dynamic IP address changes each time you dial in, whereas a static IP address remains the same. The ISP also might automatically provide your computer with the names of the domain name service (dns) servers. You need to know the telephone number that your computer will dial in to for making the connection; your ISP supplies that number, too. You will also need a working modem and need to know the device name of the modem (usually /dev/modem).
NOTE

Most IP addresses are dynamically assigned by ISPs; ISPs have a pool of addresses, and you get whatever address is available. From the ISP’s viewpoint, a small number of addresses can serve a large number of people because not everyone will be online at the same time. For most Internet services, a dynamic IP works well because it is the ISP’s job to route that information to you, and it sits in the middle—between you and the service you want to use. But a dynamic IP address changes, and if someone needs to find you at the same address (if you run a website or a file transfer site, for example), an IP that changes every time you log on will not work well. For that, you need a static IP. Because your ISP cannot reuse that IP with its other customers, it will likely charge you more for a static IP than a dynamic IP. The average consumer doesn’t need the benefit of a static IP, so he is happy paying less for a dynamically assigned IP. Also, the DNS information can be provided automatically by the ISP by the Dynamic Host Configuration Protocol, or DHCP.

If you are using DSL access or a cable modem, you might have a dynamic IP provided through DHCP, or you might be assigned a static IP. You might automatically be provided with the names of the DNS servers if you use DHCP, or you might have to set up DNS manually (in which case, you have to know the IP addresses of the DNS servers).

In all cases, you have to know your username, your password, and for the configuration of other services, the names of the mail servers and the news server. This information can be obtained from your ISP if you specifically ask for it.

NOTE

The information in this book will help you understand and avoid many connection issues, but you might experience connection problems. Keep the telephone number of the technical help service for your ISP on hand in case you are not able to establish a connection. But be aware that few ISPs offer Linux support, and you might need to seek help from a Linux-savvy friend or a Linux user’s group if your special circumstances cannot be handled from the knowledge you gain from this book. Of course, the best place to look is on the Internet. Use Google’s Linux page (www.google.com/linux/) to research the problem and see if any other users have found fixes or workarounds.

Configuring Digital Subscriber Line Access

Ubuntu also supports the use of a digital subscriber line (DSL) service. Although it refers to the different types of DSL available as xDSL, that name includes ADSL, IDSL, SDSL, and other flavors of DSL service; they can all be configured using the Internet Connection Wizard. DSL service generally provides 256Kbps to 24Mbps transfer speeds and transmits data over copper telephone lines from a central office to individual subscriber sites (such as your home). Many DSL services provide asymmetric speeds with download speeds greater than upload speeds.
NOTE

DSL service is an “always-on” type of Internet service, although you can turn off the connection under Ubuntu using the network configuration tool found under System, Administration, Network. An always-on connection exposes your computer to malicious abuse from crackers who trawl the Internet attempting to gain access to other computer systems. In addition to the capability to turn off such connections, Ubuntu is also preconfigured to not listen on any network ports, which means that any attempts to gain access to your computer will fail because Ubuntu will reject the request. This is the Ubuntu equivalent of putting up a 12-foot steel fence surrounding your computer.

A DSL connection requires that you have an ethernet network interface card (sometimes a USB interface that is not easily supported in Linux) in your computer or notebook. Many users also configure a gateway, firewall, or other computer with at least two network interface cards to share a connection with a LAN. We looked at the hardware and protocol issues earlier on in this chapter. Advanced configuration of a firewall or router, other than what was addressed during your initial installation of Ubuntu, is beyond the scope of this book.

Understanding Point-to-Point Protocol over Ethernet

Establishing a DSL connection with an ISP providing a static IP address is easy. Unfortunately, many DSL providers use a type of PPP protocol named Point-to-Point Protocol over Ethernet (PPPoE) that provides dynamic IP address assignment and authentication by encapsulating PPP information inside ethernet frames. Roaring Penguin’s rp-pppoe clients are available from the Roaring Penguin site (www.roaringpenguin.com/penguin/pppoe/rp-pppoe-3.8.tar.gz), and these clients make the difficult-to-configure PPPoE connection much easier to deal with. You can download and install newer versions (see the Roaring Penguin link in the “Reference” section at the end of this chapter).

NOTE

ADSL modems were frequently supplied by ISPs when they originally started to roll out ADSL services. Today however, in much of the world these modems are optional, which is a good thing because many people choose to purchase a router with an in-built modem to create a dedicated connection. In the United States, these devices are very rare, but you can usually replace the supplied modem with an aftermarket modem if you want to spend the money. Either way, using a router can save many headaches and will allow you to easily connect more than one computer to an Internet connection.

Note that if you are using a cable connection then they usually come with an ethernet cable, in which case you just need a router (which is pretty much how all Internet access works in the United States, because combination modem/router devices are very rare in the U.S.). Check with your ISP before buying to ensure that whatever router you do end up with can be supported by them. You might find that your ISP even supplies a router as part of the package!
Configuring a PPPoE Connection Manually

You should only need to use these steps if you are using a modem supplied by your ISP, and not a router. The basic steps involved in manually setting up a DSL connection using Ubuntu involve connecting the proper hardware, and then running a simple configuration script if you use rp-pppoe from Roaring Penguin.

First, connect your DSL modem to your telephone line, and then plug in your ethernet cable from the modem to your computer’s network interface card. If you plan to share your DSL connection with the rest of your LAN, you need at least two network cards—designated eth0 (for your LAN) and eth1 (for the DSL connection).

The following example assumes that you have more than one computer and will share your DSL connection on a LAN.

First, log in as root, and ensure that your first eth0 device is enabled and up (perhaps using the ifconfig command). Next, bring up the other interface, but assign a null IP address like this:

```
matthew@seymour:~$ sudo /sbin/ifconfig eth1 0.0.0.0 up
```

Now use the adsl-setup command to set up your system. Type the command like this:

```
matthew@seymour:~$ sudo /sbin/adsl-setup
```

You will be presented with a text script and be asked to enter your username and the Ethernet interface used for the connection (such as eth1). You will then be asked to use “on demand” service or have the connection stay up all the time (until brought down by the root operator). You can also set a timeout in seconds, if desired. You’ll then be asked to enter the IP addresses of your ISP’s DNS servers if you haven’t configured the system’s /etc/resolv.conf file.

After that, you will be prompted to enter your password two times, and have to choose the type of firewall and IP masquerading to use. (You learned about IP masquerading in the “Using IP Masquerading in Ubuntu” section, earlier in this chapter.) The actual configuration is done automatically. Using a firewall is essential today, so you should choose this option unless you intend to craft your own set of firewall rules—a discussion of which is beyond the scope of this book. After you have chosen your firewall and IP masquerading setup, you will be asked to confirm, save, and implement your settings. You are also given a choice to allow users to manage the connection, a handy option for home users.

Changes will be made to your system’s /etc/sysconfig/network-scripts/ifcfg-ppp0, /etc/resolv.conf, /etc/ppp/pap-secrets, and /etc/ppp/chap-secrets files.

After configuration has finished, use the adsl-start command to start a connection and DSL session, like this:

```
matthew@seymour:~$ sudo /sbin/adsl-start
```

The DSL connection should be nearly instantaneous, but if problems occur, check to make sure that your DSL modem is communicating with the phone company’s central office by examining the status LEDs on the modem. Because this varies from modem to modem, consult your modem user’s manual.
Make sure all cables are properly attached, that your interfaces are properly configured, and that you have entered the correct information to the setup script.

If IP masquerading is enabled, other computers on your LAN on the same subnet address (such as 192.168.0.XXX) can use the Internet, but must have the same /etc/resolv.conf name server entries and a routing entry with the DSL-connected computer as a gateway. For example, if the host computer with the DSL connection has an IP address of 192.168.0.1, and other computers on your LAN use addresses in the 192.168.0.XXX range, use the route command on each computer like this:

```bash
matthew@seymour:~$ sudo /sbin/route add default gw 192.168.0.1
```

Note that you can also use a hostname instead if each computer has an /etc/hosts file with hostname and IP address entries for your LAN. To stop your connection, use the adsl-stop command like this:

```bash
matthew@seymour:~$ sudo /sbin/adsl-stop
```

Configuring Dial-Up Internet Access

Most ISPs provide dial-up connections supporting PPP because it is a fast and efficient protocol for using TCP/IP over serial lines. PPP is designed for two-way networking; TCP/IP provides the transport protocol for data. One hurdle faced by new Ubuntu users is how to set up PPP and connect to the Internet. It is not necessary to understand the details of the PPP protocol to use it, and setting up a PPP connection is easy. You can configure the PPP connections manually using the command line or graphically during an X session using Ubuntu’s Network Configuration Tool. Each approach produces the same results.

PPP uses several components on your system. The first is a daemon called pppd, which controls the use of PPP. The second is a driver called the high-level data link control (HDLC), which controls the flow of information between two machines. A third component of PPP is a routine called chat that dials the other end of the connection for you when you want it to. Although PPP has many “tunable” parameters, the default settings work well for most people.

Ubuntu includes some useful utilities to get your dial-up connection up and running. In this section we will take a look at two options that will have you on the Internet in no time.

The first way is to configure a connection using pppconfig, a command line utility to help you to configure specific dial-up connection settings.

Enter the following command:

```bash
matthew@seymour:~$ sudo pppconfig
```

Before you connect for the first time you need to add yourself to both the dip and dialout groups by using the commands:

```bash
matthew@seymour:~$ sudo adduser YOURNAMEHERE dip
matthew@seymour:~$ sudo adduser YOURNAMEHERE dialout
```

After this has been done it is just a simple matter of issuing the pon command to connect, and the poff command to disconnect. You can create as many different profiles as you
need, and can launch specific ones by using the command `pon profilename`, again using the `poff` command to disconnect.

**CAUTION**

Many software modems will not work with Linux because the manufacturers will not release programming information about them or provide Linux drivers. An external serial port modem or ISA bus modem will almost always work; USB and PCI modems are still problematic. It is suggested that you do a thorough Google search using your modem’s name and model number to see how others have solved problems with that particular modem. Links to software modem compatibility sites appear at the end of this chapter.

**Troubleshooting Connection Problems**

The Linux Documentation Project at www.tldp.org/ offers many in-depth resources for configuring and troubleshooting these connections. The Internet search engine Google is also an invaluable tool for dealing with specific questions about these connections. For many other useful references, see the “Reference” section at the end of this chapter.

Here are a few troubleshooting tips culled from many years of experience:

- If your modem connects and then hangs up, you are probably using the wrong password or dialing the wrong number. If the password and phone number are correct, it is likely an authentication protocol problem.

- If you get connected but cannot reach websites, it is likely a domain name resolver problem, meaning that DNS is not working. If it worked yesterday and you haven’t “adjusted” the associated files, it is probably a problem at the ISP’s end. Call and ask.

- Always make certain that everything is plugged in. Check again—and again.

- If the modem works in Windows, but not in Linux no matter what you do, it is probably a software modem no matter what it said on the box.

- If everything just stops working (and you do not see smoke), it is probably a glitch at the ISP or the telephone company. Take a break and give them some time to fix it.

- Never configure a network connection when you have had too little sleep or too much caffeine; you will just have to redo it tomorrow.

**RELATED UBUNTU AND LINUX COMMANDS**

You will use these commands when managing network connectivity in your Ubuntu system:

- `dhclient`—Automatically acquire, and then set IP info for a NIC
- `ethereal`—GNOME graphical network scanner
- `firestarter`—Ubuntu’s basic graphical firewalling tool for X
ifconfig—Displays and manages Linux networking devices
iwconfig—Displays and sets wireless network device parameters
route—Displays and manages Linux kernel routing table
ssh—The OpenSSH remote-login client and preferred replacement for telnet
nm-connection-editor—Ubuntu’s GUI for configuring network connections

CHAPTER 15
Remote Access with SSH and Telnet

Controlling your system remotely is one of the cooler things you can do with Ubuntu—with just a bit of configuration, you can connect from any Linux box to another computer in a variety of ways. If you just want to check something quickly or if you have limited bandwidth, you have the option of using only the command line, but you can also connect directly to the X server and get full graphical control.

Understanding the selection of tools available is largely a history lesson. For example, Telnet was an earlier way of connecting to another computer through the command line, but that has since been superseded by SSH. That is not to say that you should ignore Telnet; you need to know how to use it so you have it as a fallback. However, SSH is preferred because it is more secure. We cover both in this chapter.

Setting Up a Telnet Server

Telnet is an older service. The client is part of the default installation, but is not activated by default. The server is not part of the default installation. This is because everything Telnet transmits and receives is in plain text, including passwords and other sensitive information. Telnet is generally not a good choice for communication. However, you may want to install Telnet for certain situations, such as connecting to piece of equipment that doesn’t have SSH available, such as embedded systems where having a small OS footprint is important and more secure methods of communication are not available. In addition, sometimes Telnet is the quickest and easiest way to test newly installed
services during configuration, such as a Postfix mail server. You might also want to install Telnet to learn about it and test it, simply because you may run across moments in the real world where no other option exists.

If you decide to install Telnet, use Synaptic or apt to install `telnetd`. This will install the server.

Start by configuring your firewall to allow connections through port 23. If this port is blocked, you will not be able to use Telnet. See Chapter 33, “Securing Your Machines,” for help doing this.

After that is configured, type `telnet <your IP>`. This will test to confirm both the client and server are installed and working by connecting from your terminal using the client back to the server running on your own computer. You are prompted to enter your username and password. The whole conversation should look something like this:

```
matthew@seymour:~$ telnet 192.168.1.102
Trying 192.168.1.102...
Connected to 192.168.1.102 (192.168.1.102)
Escape character is '^]'.

Welcome to babbage
Ubuntu 10.04 LTS

* All access is logged *

login: matthew
Password:
Last login: Sun Jul 4 10:08:34 2010 from seymour
matthew@babbage~$
```

**TIP**

The server responds with `Welcome to babbage, Ubuntu 10.04 LTS`, which is a customized message. Your machine will respond similarly. This may be insecure: giving away version numbers is never a smart move on a machine that may be accessed from outside of a secure network. In fact, even saying `Ubuntu` is questionable. In those instances, you can edit the `issue` and `issue.net` files in your `/etc` directory to change the message displayed.

To use Telnet to connect to a different computer, use that computer’s IP address on the network instead of using your own. You can use Telnet on local networks as well as across the internet to connect to any computer running the server on an open port.
Telnet uses port 23, but you can use it with other ports by adding the port to the IP address like in this example where we use it to connect to port 110 to test a POP3 connection/server:

matthew@seymour:~$ telnet 192.168.1.102 110

### Telnet Versus SSH

Although Telnet is worth keeping around as a fail-safe, last resort option, SSH is superior in virtually every way. Telnet is fast but also insecure. As stated earlier, it sends all your text, including your password, in plain text that can be read by anyone with the right tools. SSH, on the other hand, encrypts all your communication and so is more resource-intensive but secure—even a government security agency sniffing your packets for some reason would still have a hard time cracking the encryption.

Andy Green, posting to the fedora-list mailing list, summed up the Telnet situation perfectly when he said, “As Telnet is universally acknowledged to encourage evil, the service telnetd is not enabled by default.” It is worthwhile taking the hint: Use Telnet as a last resort only.

### Setting Up an SSH Server

If not installed already, the OpenSSH server can be installed through Synaptic by adding the openssh-server package. As you might have guessed, sshd is the name for the SSH server daemon.

Start by configuring your firewall to allow connections through port 22. If this port is blocked, you will not be able to use SSH. See Chapter 33 for help doing this.

Two different versions of SSH exist, SSH1 and SSH2. The latter is newer, more secure, comes with more features, and is the default in Ubuntu. Support for SSH1 clients is best left disabled so older clients can not connect. This is done by default in the /etc/ssh/sshd_config file on this line:

```
Protocol 2
```

If you have no other option and absolutely have to allow an older client to connect, add a new line:

```
Protocol 1
```
SSH Tools

To the surprise of many, OpenSSH actually comprises a suite of tools. We have already seen `ssh`, the secure shell command that connects to other machines, and `sshd`, the SSH server daemon that accepts incoming SSH connections. However, there is also `sftp`, a replacement for `ftp`, `scp`, and `rcp`.

You should already be familiar with the `ftp` command because it is the lowest-common-denominator system for handling FTP file transfers. Like Telnet, though, `ftp` is insecure: It sends your data in plain text across the network and anyone can sniff your packets to pick out a username and password. The SSH replacement, `sftp`, puts FTP traffic over an SSH link, thus securing it.

The `rcp` command might be new to you, largely because it is not used much anymore. Back in its day, `rcp` was the primary way of copying a single file to another server. As with `ftp`, `scp` replaces `rcp` by simply channeling the data over a secure SSH connection. The difference between `sftp` and `scp` is that the former allows you to queue and copy many files at once, whereas the latter is usually used to just send one, although `scp` can be used with the `-r` option to send an entire directory at once. See the man page for details.

Using `scp` to Copy Individual Files Between Machines

The most basic use of the `scp` command is to copy a file from your current machine to a remote machine. You can do that with the following command:

```
scp test.txt 192.168.1.102:
```

The first parameter is the name of the file you want to send, and the second is the server to which you want to send it. Note that there is a colon at the end of the IP address. This is where you can specify an exact location for the file to be copied. If you have nothing after the colon, as in the previous example, `scp` copies the file to your home directory. As with SSH, `scp` prompts you for your password before copying takes place.

You can rewrite the previous command so you copy `test.txt` from the local machine and save it as `newtest.txt` on the server:

```
scp test.txt 192.168.1.102:newtest.txt
```

Alternatively, if there is a directory where you want the file to be saved, you can specify it like this:

```
scp test.txt 192.168.1.102:subdir/stuff/newtest.txt
```

The three commands so far have all assumed that your username on your local machine is the same as your username on the remote machine. If this is not the case, you need to specify your username before the remote address, like this:

```
scp test.txt usernamesnewtest.txt
```
You can use `scp` to copy remote files locally, simply by specifying the remote file as the source and the current directory (.) as the destination:

```
scp 192.168.1.102:remote.txt .
```

If you want to copy files from one remote machine to another remote machine using `scp`, the best method is to first `ssh` to one of the remote machines and then use `scp` from that location.

### Using `sftp` to Copy Many Files Between Machines

`sftp` is a mix between `ftp` and `scp`. Connecting to the server uses the same syntax as `scp`—you can just specify an IP address to connect using your current username, or you can specify a username using `username@ipaddress`. You can optionally add a colon and a directory, as with `scp`. After you are connected, the commands are the same as `ftp`: `cd`, `put`, `mput`, `get`, `quit`, and so on.

In one of the `scp` examples, we copied a remote file locally. You can do the same thing with `sftp` with the following conversation:

```
matthew@seymour:~$ sftp 192.168.1.102
Connecting to 192.168.1.102...
matthew@192.168.1.102's password:
sftp> get remote.txt
Fetching /home/matthew/remote.txt to remote.txt
/home/matthew/remote.txt      100%  23   0.0KB/s   00:00
sftp> quit
matthew@seymour:~$
```

Although FTP remains prominent because of the number of systems that do not have support for SSH, SFTP is gaining in popularity. Apart from the fact that it secures all communications between client and server, SFTP is popular because the initial connection between the client and server is made over port 22 through the `sshd` daemon. Someone using SFTP connects to the standard `sshd` daemon, verifies himself, and then is handed over to the SFTP server. The advantage to this is that it reduces the attack vectors because the SFTP server cannot be contacted directly and so cannot be attacked as long as the `sshd` daemon is secure.

### Using `ssh-keygen` to Enable Key-Based Logins

There is a weak link in the SSH system, and, inevitably, it lies with users. No matter what lengths system administrators go to in training users to be careful with their passwords, monitors around the world have Post-it notes attached to them with “pAssw0rd” written on them. Sure, it has a mix of letters and numbers, but it can be cracked in less than a
second by any brute-force method. Brute-forcing is the method of trying every password possibility, starting with likely words (such as password and variants, or god) and then just trying random letters (for example, a, aa, ab, ac, and so on).

Even very strong passwords are no more than about 16 characters; such passwords take a long time to brute-force but can still be cracked. The solution is to use key-based logins, which generate a unique, 1024-bit private and public key pair for your machine. These keys take even the fastest computers a lifetime to crack, and you can back them up with a password to stop others from using them.

Creating an SSH key is done through the ssh-keygen command, like this:

```bash
matthew@seymour:~$ ssh-keygen -t dsa
```

Press Enter when it prompts you where to save your key, and enter a passphrase when it asks you to. This passphrase is just a password used to protect the key—you can leave it blank if you want to, but doing so would allow other people to use your account to connect to remote machines if they manage to log in as you.

After the key is generated, change the directory to `.ssh (cd ~/.ssh), which is a hidden directory where your key is stored and also where it keeps a list of safe SSH hosts. Assuming you use the default options, here you will see the files `id_dsa` and `id_dsa.pub`. The first is your private key and should never be given out. The second is your public key, which is safe for distribution. You need to copy the public key to each server you want to connect to via key-based SSH.

Using `scp`, you can copy the public key over to your server, like this:

```bash
matthew@seymour:~$ scp id_dsa.pub 192.186.1.102:
```

This places `id_dsa.pub` in your home directory (for an account that uses the same user-name as your local account) on `192.186.1.102`. The next step is to SSH into `192.186.1.102` normally and set up that key as an authorized key. So, you can SSH in as yourself:

```bash
matthew@seymour:~$ ssh 192.168.1.102
```

After logging in normally, type:

```bash
matthew@babbage:~$ cat id_dsa.pub >> .ssh/authorized_keys
matthew@babbage:~$ chmod 400 .ssh/authorized_keys
```

The `touch` command creates the `authorized_keys` file (if it does not exist already); then you use `cat` to append the contents of `id_dsa.pub` to the list of already authorized keys. Finally, `chmod` is used to make `authorized_keys` read-only.

With that done, you can type `exit` to disconnect from the remote machine and return to your local machine. Then you can try running `ssh` again. If you are prompted for your passphrase, you have successfully configured key-based authentication.
That is the current machine secured, but what about every other machine? It is still possible to log in from another machine using only a password, which means your remote machine is still vulnerable.

The solution to this is to edit the `/etc/ssh/sshd_config` file. This will require super-user privileges. Look for the PasswordAuthentication line and make sure it reads `no` (and that it is not commented out with a `#`). Save the file, and run `kill -HUP 'cat /var/run/sshd.pid'` to have `sshd` reread its configuration files. With that done, `sshd` accepts only connections from clients with authorized keys, which stops crackers from brute-forcing their way in.

**TIP**

For extra security, you are strongly encouraged to set `PermitRootLogin` to `no` in `/etc/ssh/sshd_config`. When this is set, it becomes impossible to SSH into your machine using the root account—you must connect with a normal user account and then use `su` or `sudo` to switch to root. This is advantageous because most brute-force attempts take place on the root account because it is the only account that is guaranteed to exist on a server.

Also, even if a cracker knows your user account, she has to guess both your user password and your root password to take control of your system.

Of course, if you don’t have a root account enabled on your box, this isn’t an issue because it is already impossible to log in directly as root. Hooray for slightly more secure defaults in Ubuntu!

---

**Virtual Network Computing (VNC)**

Everything we have looked at so far has been about remote access using the command-line, with no mention so far of how to bring up a graphical user interface. There are several ways of doing this in Ubuntu, some of which are linked in the “Reference” section later in this chapter. Here we will discuss the most popular and the most preferred by the Ubuntu community, which is also the best supported by the developers: Virtual Network Computing (VNC).

VNC is a system for controlling a computer remotely and sharing desktops over a network using a graphical interface. It was created at the Olivetti & Oracle Research Lab, which was acquired by AT&T in 1999 and closed down in 2001. Since then, several of the members of the development team got together to create a free and open source version of the code (using the GPL), and from that base many different version have appeared. VNC is widespread in the Linux world and, to a lesser extent, in the Windows world. Its main advantage is its widespread nature: nearly all Linux distros bundle VNC, and clients are available for a wide selection of platforms.
Start by configuring your firewall to allow connections through port 5900. If this port is blocked, you will not be able to use VNC. See Chapter 33, “Securing Your Machines,” for help doing this.

To set up VNC on your Ubuntu computer to allow others to access your desktop, you only need to tell Ubuntu who should be allowed to connect to your session. This is done from the menu at System, Preferences, Remote Desktop. By default, your desktop is not shared. Check Allow other users to view your desktop to Share It. Most likely, you also want to check Allow other users to control your desktop; otherwise, people will be able to see what you are doing but not interact with the desktop—which is not very helpful. If you are using this as a remote way to connect to your own desktop or one that is running unattended when you will need access, uncheck You must confirm each access to this machine. If this is not done, when you try to connect from your remote location, Ubuntu will pop up a message box on the local machine asking Should This Person Be Allowed to Connect? Because you are not there to click Yes, the connection will fail. If you want to let someone else remotely connect to your system, keep this box enabled so you know when people are connecting. You should always enter a password, no matter who it is that will connect. The options suggested are shown in Figure 15.1.

To access a computer that is running VNC from your Ubuntu desktop, in the menu click Applications, Internet, Remote Desktop Viewer. The program starts by searching the local network for shared desktops. If any are found, they will be listed. In Figure 15.2, Heather’s computer is shown.

From the screen in Figure 15.2, click Connect. You will then be allowed to select one of the hosts shown in the previous list from a drop box, find others on the network, or enter an IP address of your choosing that correlates to a computer you have already set up.
somewhere to be accessed using VNC as in Figure 15.3. Then choose your other options and click Connect to begin.

![Remote Desktop Viewer](image)

**FIGURE 15.2** Remote Desktop Viewer.

![Choose machine to connect](image)

**FIGURE 15.3** Choose the machine to which you want to connect.

When you are finished, click Close.

VNC should not be considered secure over the Internet or on untrusted internal networks.

- www.nomachine.com/—Another alternative to VNC is in the pipeline, called NX. The free implementation, FreeNX, is under heavy development at the time of writing but promises to work much faster than VNC.
In the early days of computing, file and printer sharing was pretty much impossible because of the lack of good networking standards and interoperability. If you wanted to use a printer connected to another computer, you had to save the file to a floppy disk and walk over. Sometimes people do the same thing today using a USB thumb drive or emailing the file. However, there are better ways.

Both file and printer sharing are important because it is not unusual for someone to own more than one computer. Whether you want to share photographs among various computers or have a central repository available for collaboration, file sharing is an important part of our information age. Alongside this is the need to be able to share printers; after all, people do not want to have to plug and unplug a computer to a printer just so they can print out a quick letter.

Whatever your reasons for needing to share files and printers across a network, you find out how to do both in this chapter. We look at how you can share files using the popular UNIX NFS protocol and the more Windows-friendly Samba system. You also find out how to configure network-attached printers with interfaces such as JetDirect. We look at both graphical and command-line tools, so you should find something to suit the way you work.
Using the Network File System

Network File System (NFS) is the protocol developed by Sun Microsystems that allows computers to use a remote file system as if it were a real part of the local machine. A common use of NFS is to allow users’ home directories to appear on every local machine they use, thus eliminating the need to have physical home directories. This opens up hot desking and other flexible working arrangements, especially because no matter where the users are, their home directory follows them around.

Another popular use for NFS is to share binary files between similar computers. If you have a new version of a package that you want all machines to have, you have to upgrade only on the NFS server, and all hosts running the same version of Ubuntu will have the same upgraded package.

Installing and Starting or Stopping NFS

NFS is not installed by default on Ubuntu, so you need to install the `nfs-kernel-server` package. NFS itself consists of several programs that work together. One is `portmap`, which maps NFS requests to the correct daemon. Two others are `nfsd`, which is the NFS daemon, and `mountd`, which controls the mounting and unmounting of file systems.

Ubuntu automatically adds NFS to the system startup scripts, so it will always be available after you have configured it. To check this, use the command `sudo /etc/init.d/nfs-kernel-server status` and it will show you that the service is running. If you need to manually start the NFS server, use the following command:

```
matthew@seymour:~$ sudo /etc/init.d/nfs-kernel-server start
* Exporting directories for NFS kernel daemon:  [ OK ]
Starting NFS kernel daemon:                        [ OK ]
```

In this example, NFS has been started. Use `stop` to stop the service, or `restart` to restart the server. This approach to controlling NFS proves handy, especially after configuration changes have been made. See the next section on how to configure NFS support on your Ubuntu system.

NFS Server Configuration

You can configure the NFS server by editing the `/etc/exports` file. This file is similar to the `/etc/fstab` file in that it is used to set the permissions for the file systems being exported. The entries look like this:

```
/file/system yourhost(options) *.yourdomain.com(options) 192.168.0.0/24(options)
```
This shows three common clients to which to share /file/system. The first, yourhost, shares /file/system to just one host. The second, .yourdomain.com, uses the asterisk (*) as a wildcard to enable all hosts in yourdomain.com to access /file/system. The third share enables all hosts of the Class C network, 192.168.0.0, to access /file/share. For security, it is best not to use shares, such as the last two across the Internet, because all data will be readable by any network the data passes by.

Table 16.1 shows some common options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>Gives read and write access</td>
</tr>
<tr>
<td>ro</td>
<td>Gives read-only access</td>
</tr>
<tr>
<td>async</td>
<td>Writes data when the server, not the client, feels the need</td>
</tr>
<tr>
<td>sync</td>
<td>Writes data as it is received</td>
</tr>
</tbody>
</table>

The following is an example of an /etc/exports file:

```
# /etc/exports: the access control list for filesystems which may be exported to NFS clients. See exports(5).
/home/matthew 192.168.0.0/24(rw,no_root_squash)
```

This file exports (makes available) /home/matthew to any host in 192.168.0.* and allows users to read from and write to /home/matthew.

After you have finished with the /etc/exports file, the following command exports all the file systems in the /etc/exports file to a list named xtab under the /var/lib/nfs directory, which is used as a guide for mounting when a remote computer asks for a directory to be exported:

```
matthew@seymour:~$ sudo exportfs -a
```

The -r option stands for reexport and tells the command to rereads the entire /etc/exports file and (re)mount all the entries. You can also use the exportfs command to export specific files temporarily. Here’s an example using exportfs to export a file system:

```
matthew@seymour:~$ /usr/sbin/exportfs -o async yourhost:/usr/tmp
```

This command exports /usr/tmp to yourhost with the async option.

Be sure to restart the NFS server after making any changes to /etc/exports. If you prefer, you can use Ubuntu’s shares-admin graphical client to set up NFS while using the X Window System. Start the client by clicking the System menu and then selecting the Shared Folders menu item from the Administration menu.

After you press Enter, you are prompted for your password. Type in the password and click OK; the main window will then display. Click the Add button to open the Add Share dialog box.
In the Path drop-down box, choose the directory that you want to share; in the Share drop-
down box, choose NFS. Click the Add Host button that appears to specify which hosts, IP
addresses, or networks are allowed access to the directory. By default, a directory is exported
as read/write, but you can choose read-only by ticking the Read-Only option. When
finished, click the OK button, click the Apply button, and then use the File menu to quit.

**NFS Client Configuration**

To configure your host as an NFS client (to acquire remote files or directories), you need to
ensure that you have the nfs-common package installed, to be able to access NFS shares.
After you’ve installed this, edit the `/etc/fstab` file as you would to mount any local file
system. However, instead of using a device name to be mounted (such as `/dev/sda1`),
enter the remote hostname and the desired file system to be imported. For example, one
ingry entry might look like this:

```
# Device             Mount Point  Type  Options       Freq Pass
yourhost:/home/share  /export/share   none   nfs  0    0
```

**NOTE**

If you use autofs on your system, you need to use proper autofs entries for your
remote NFS mounts. See the section 5 man page for autofs.

You can also use the `mount` command, as root, to quickly attach a remote directory to a
local file system by using a remote host’s name and exported directory. For example:

```
matthew@seymour:~$ sudo mount -t nfs 192.168.2.67:/music /music
```

After you press Enter, the entire remote directory appears on your file system. You can
verify the imported file system using the `df` command, as follows:

```
matthew@seymour:~$ df
Filesystem 1k-blocks Used Available Use% Mounted on
/dev/hda2 18714368 9642600 8121124 55% /
/dev/hda1 46636 13247 30981 30% /boot
none 120016 0 120016 0% /dev/shm
192.168.2.67:/music 36875376 20895920 14013840 60% /music
```

Make sure that the desired mount point exists before using the mount command. When
finished using the directory (perhaps for copying backups), you can use the `umount`
command to remove the remote file system. Note that if you specify the root directory (`/`) as
a mount point, you cannot unmount the NFS directory until you reboot (because Linux
complains that the file system is in use).
Putting Samba to Work

Samba uses the Session Message Block (SMB) protocol to enable the Windows operating system (or any operating system) to access Linux files. Using Samba, you can make your Ubuntu machine look just like a Windows computer to other Windows computers on your network. You do not need to install Windows on your PC.

Samba is a complex program—the Samba man page (when converted to text) for just the configuration file is 330KB and 7,226 lines long. Although Samba is complex, setting it up and using it does not have to be difficult. There are many options, which accounts for some of Samba’s complexity. Depending on what you want, Samba’s use can be as easy or as difficult as you would like it to be.

Fortunately, Ubuntu includes a very easy way to access files on a Windows network share by default. To start, click Places, Network from the menu. You will see a Windows Network icon that, when double-clicked, will show you all Windows domains or workgroups found on your network. Simply double-click any computer icon there to access shares and files.

To share from your Ubuntu desktop, simply right-click a folder you own while using the file browser, most likely one in your /home/username directory, and select Sharing Options. You will be given a chance to confirm your desire to share the folder and give it a name. Sharing gives others the permission to view, but not necessarily to create or delete files, although those permissions are also available from this menu. If you don’t have the Windows sharing service already installed on your computer, Ubuntu will prompt you for permission to install it.

NOTE

Most Ubuntu users will not need the information contained in the rest of this section because installing the sharing service also takes care of the configuration and as a result, everything should just work.

The Samba Web Administration Tool (SWAT) can be used to configure Samba from a web browser. SWAT provides an easy way to start and stop the Samba server; set up printing services; define remote access permissions; and create Samba usernames, passwords, and shared directories. This section delves into the basics of configuring Samba, and you should first read how to manually configure Samba to get an understanding of how the software works. At the end of this section, you will see how to enable, start, and use SWAT to set up simple file sharing.

Like most of the software that comes with Ubuntu, Samba is licensed under the GPL and is free. Installation is straightforward and the software is in the Ubuntu repositories. Regardless of which route you take, you should snag the samba and swat packages.

Installing from source code can be more time-consuming. If you do not want to install using Ubuntu’s default locations, however, installing from the source code is a more
configurable method. Just download the source from www.samba.org/ and unpack the files. Change into the source directory and, as root, run the command, `./configure` along with any changes from the defaults. Then run `make`, `make test` (if you want), followed by `make install` to install Samba in the specified locations.

**NOTE**

If you haven’t done so, you might need to install a meta-package (a single package that provides several related packages) called `build-essential`. This package automatically installs all the make tools, plus other development utilities that you will need to compile software from source code.

When you install Samba, it is a good idea to also install the `samba-doc` and `samba-doc-pdf` packages because they contain extensive documentation in text, PDF, and HTML format. After you install it, you can find this documentation in `/usr/share/doc/samba*/doc`. If you install Samba using your Ubuntu disc, you can find a large amount of documentation in the directory tree starting at `/usr/share/doc/samba-doc` or `/usr/share/doc/samba-doc-pdf` in several formats, including PDF, HTML, and text, among others. Altogether, almost 3MB of documentation is included with the source code.

After installing Samba, you can either create the file `/etc/samba/smb.conf` or use the `smb.conf` file supplied with Samba, which is located by default under the `/etc/samba` directory with Ubuntu. You can find nearly a dozen sample configuration files under the `/usr/share/doc/samba*/examples` directory.

**NOTE**

Depending on your needs, `smb.conf` can be a simple file of fewer than 20 lines or a huge file spanning many pages of text. If your needs are complex, I suggest you browse through The Official Samba Howto and Reference Guide, or TOSHARG. This helpful guide can be found at http://samba.org/samba/docs/man/Samba3-HOWTO/.

**Manually Configuring Samba with `/etc/samba/smb.conf`**

The `/etc/samba/smb.conf` file is broken into sections. Each section is a description of the resource shared (share) and should be titled appropriately. The three special sections are as follows:

- `[global]`—Establishes the global configuration settings (defined in detail in the `smb.conf` man page and Samba documentation, found under the `/usr/share/doc/samba/docs` directory)
- `[homes]`—Shares users’ home directories and specifies directory paths and permissions
- `[printers]`—Handles printing by defining shared printers and printer access

Each section in your `/etc/samba/smb.conf` configuration file should be named for the resource being shared. For example, if the resource `/usr/local/programs` is being shared,
you could call the section `[programs]`. When Windows sees the share, it is called by whatever you name the section (`programs` in this example). The easiest and fastest way to set up this share is with the following example from `smb.conf`:

```
[programs]
path = /usr/local/programs
writeable = true
```

This bit shares the `/usr/local/programs` directory with any valid user who asks for it and makes that directory writable. It is the most basic share because it sets no limits on the directory.

Here are some parameters you can set in the sections:

- Requiring a user to enter a password before accessing a shared directory
- Limiting the hosts allowed to access the shared directory
- Altering permissions users are allowed to have on the directory
- Limiting the time of day during which the directory is accessible

The possibilities are almost endless. Any parameters set in the individual sections override the parameters set in the `[global]` section. The following section adds a few restrictions to the `[programs]` section:

```
[programs]
path = /usr/local/programs
writeable = true
valid users = mhelmke
browseable = yes
create mode = 0700
```

The valid users entry limits `userid` to just `mhelmke`. All other users can browse the directory because of the `browseable = yes` entry, but only `mhelmke` can write to the directory. Any files created by `ahudson` in the directory give `ahudson` full permissions, but no one else will have access to the file. This is the same as setting permissions with the `chmod` command. Again, there are numerous options, so you can be as creative as you want to when developing sections.

**Setting Global Samba Behavior with the `[global]` Section**

The `[global]` section set parameters establishes configuration settings for all of Samba. If a given parameter is not specifically set in another section, Samba uses the default setting in the `[global]` section. The `[global]` section also sets the general security configuration for Samba. The `[global]` section is the only section that does not require the name in brackets.

Samba assumes that anything before the first bracketed section not labeled `[global]` is part of the global configuration. (Using bracketed headings in `/etc/samba/smb.conf` makes your configuration file more readable.) The following sections discuss common Samba settings to share directories and printers. You will then see how to test your Samba configuration.
Sharing Home Directories Using the [homes] Section

The [homes] section shares out Ubuntu home directories for the users. The home directory is shared automatically when a user’s Windows computer connects to the Linux server holding the home directory. The one problem with using the default configuration is that the users see all the configuration files (such as .profile and others with a leading period in the filename) that they normally wouldn’t see when logging on through Linux. One quick way to avoid this is to include a path option in the [homes] section. To use this solution, any users who require a Samba share of their home directory need a separate “home directory” to act as their Windows home directory.

For example, this pseudo home directory could be a directory named share in each user’s home directory on your Ubuntu system. You can specify the path option when using SWAT by using the %u option when specifying a path for the default homes shares (see the section, “Configuring Samba Using SWAT” later in this chapter). The complete path setting would be this:

```
/home/%u/share
```

This setting specifies that the directory named share under each user’s directory is the shared Samba directory. The corresponding manual smb.conf setting to provide a separate “home directory” looks like this:

```
[homes]
  comment = Home Directories
  path = /home/%u/share
  valid users = %S
  read only = No
  create mask = 0664
  directory mask = 0775
  browseable = No
```

If you have a default [homes] section, the share shows up in the user’s Network Neighborhood as the user’s name. When the user connects, Samba scans the existing sections in smb.conf for a specific instance of the user’s home directory. If there is not one, Samba looks up the username in /etc/passwd. If the correct username and password have been given, the home directory listed in /etc/passwd is shared out at the user’s home directory. Typically, the [homes] section looks like this (the browseable = no entry prevents other users from being able to browse your home directory and is a good security practice):

```
[homes]
  browseable = no
  writable = yes
```

This example shares out the home directory and makes it writable to the user. Here's how you specify a separate Windows home directory for each user:

```
[homes]
browsable = no
writable = yes
path = /path/to/windows/directories
```

**Sharing Printers by Editing the [printers] Section**

The [printers] section works much like the [homes] section but defines shared printers for use on your network. If the section exists, users have access to any printer listed in your Ubuntu /etc/printcap file.

Like the [homes] section, when a print request is received, all the sections are scanned for the printer. If no share is found (with careful naming, there should not be unless you create a section for a specific printer), the /etc/printcap file is scanned for the printer name that is then used to send the print request.

For printing to work properly, you must correctly set up printing services on your Ubuntu computer. A typical [printers] section looks like the following:

```
[printers]
comment = Ubuntu Printers
browseable = no
printable = yes
path = /var/spool/samba
```

The /var/spool/samba is a spool path set just for Samba printing.

**Testing Samba with the testparm Command**

After you have created your /etc/smb.conf file, you can check it for correctness by using the testparm command. This command parses through your /etc/smb.conf file and checks for any syntax errors. If none are found, your configuration file will probably work correctly. It does not, however, guarantee that the services specified in the file will work. It is merely making sure that the file is correctly written.

As with all configuration files, if you are modifying an existing, working file, it is always prudent to copy the working file to a different location and modify that file. Then, you can check the file with the testparm utility. The command syntax is as follows:

```
matthew@seymour:~$ sudo testparm /path/to/smb.conf.back-up
Load smb config files from smb.conf.back-up
Processing section "[homes]"
```
This output shows that the Samba configuration file is correct, and, as long as all the services are running correctly on your Ubuntu machine, Samba should be working correctly. Now copy your old `smb.conf` file to a new location, put the new one in its place, and restart Samba with the command `/etc/init.d/smbd restart`. Your new or modified Samba configuration should now be in place.

### Starting, Stopping, and Restarting the `smbd` Daemon

Once your `smb.conf` file is correctly configured, you may want to start, stop, or restart your Samba server daemon. This can be done with the `/usr/sbin/smbd` command, which (with no options) starts the Samba server with all the defaults. The most common option you will change in this command is the location of the `smb.conf` file; you change this option if you don’t want to use the default location `/etc/smb/smb.conf`. The `-s` option allows you to change the `smb.conf` file Samba uses; this option is also useful for testing whether a new `smb.conf` file actually works. Another useful option is the `-l` option, which specifies the log file Samba uses to store information.

To start, stop, or restart Samba from the command line, use the `/etc/init.d/samba` script with a proper keyword, such as start, like this:

```
matthew@seymour:~$ sudo /etc/init.d/samba start
```

### Using the `smbstatus` Command

The `smbstatus` command reports on the current status of your Samba connections. The syntax is as follows:

```
/usr/bin/smbstatus [options]
```

Table 16.2 shows some of the available options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-b</code></td>
<td>Brief output</td>
</tr>
<tr>
<td><code>-d</code></td>
<td>Verbose output</td>
</tr>
<tr>
<td><code>-s /path/to/config</code></td>
<td>Used if the configuration file used at startup is not the standard one</td>
</tr>
<tr>
<td><code>-u username</code></td>
<td>Shows the status of a specific user’s connection</td>
</tr>
<tr>
<td><code>-p</code></td>
<td>Lists current <code>smb</code> processes, which can prove useful in scripts</td>
</tr>
</tbody>
</table>

### Connecting with the `smbclient` Command

The `smbclient` command allows users on other Linux hosts to access your `smb` shares. You cannot mount the share on your host, but you can use it in a way that is similar to an FTP.
client. Several options can be used with the `smbclient` command. The most frequently used is `-I` followed by the IP address of the computer to which you are connecting. The `smbclient` command does not require root access to run:

```
matthew@seymour:~$ smbclient -I 10.10.10.20 -U username%password
```

This gives you the following prompt:

```
smb: <current directory on share>
```

From here, the commands are almost identical to the standard UNIX/Linux FTP commands. Note that you can omit a password on the `smbclient` command line. You are then prompted to enter the Samba share password.

### Mounting Samba Shares

There are two ways to mount Samba shares to your Linux host. Mounting a share is the same as mounting an available media partition or remote NFS directory except that the Samba share is accessed using SMB. The first method uses the standard Linux `mount` command:

```
matthew@seymour:~$ sudo mount -t smbfs //10.10.10.20/homes /mount/point -o username=heather,dmask=777,\fmask=777
```

**NOTE**

You can substitute the IP address for hostname if your name service is running or the host is in your `/etc/hosts` file.

This command mounts `heather`'s home directory on your host and gives all users full permissions to the mount. The permissions are equal to the permissions on the `chmod` command.

The second method produces the same results using the `smbmount` command, as follows:

```
matthew@seymour:~$ sudo smbmout //10.10.10.20/homes /mount/point -o username=heather,dmask=777,\fmask=777
```

To unmount the share, use the following standard command:

```
matthew@seymour:~$ sudo umount /mount/point
```

You can also use these mount commands to mount true Windows client shares to your Ubuntu host. Using Samba, you can configure your server to provide any service Windows can serve, and no one but you will ever know.
Configuring Samba Using SWAT

The Samba team of developers has made administering Samba much easier with the Samba Web Administration Tool (SWAT). SWAT is a web-based configuration and maintenance interface that gets as close to a point-and-click Samba environment as possible. This section provides a simple example of how to use SWAT to set up SMB access to a user’s home directory and how to share a directory.

NOTE

You need to enable the root account by giving it a password by using the command `sudo passwd root`. Not enabling the root account prevents you from using SWAT effectively.

You need to perform a few steps before you can start using SWAT. First, make sure you have the Samba and the `swat` packages installed. You then enable SWAT access to your system by editing the `/etc/inetd.conf` file by changing the following lines to remove the `#<off>#' comments if present:

```
#<off># swat  stream  tcp  nowait.400  root
   /usr/sbin/tcpd  /isr/sbin/swat
```

Save the file, and then restart the `openbsd_inetd` daemon using the following command:

```
matthew@seymour:~$ sudo /etc/init.d/openbsd-inetd restart
```

Next, start an X session, launch Firefox, and browse to the http://localhost:901 uniform resource locator (URL). You are presented a login prompt. Enter the root username and password, and then click the OK button. The screen clears, and you see the main SWAT page, as shown in Figure 16.1.

TIP

You can also configure Samba using Ubuntu’s `shares-admin` client. Launch the client from the command line of an X terminal window or select the System, Administration, Shared Folders menu item.

First, click the Globals icon in SWAT’s main page. You see a page similar to the one shown in Figure 16.2. Many options are in the window, but you can quickly set up access for hosts from your LAN by simply entering one or more IP addresses or a subnet address (such as 192.168.0.—note the trailing period, which allows access for all hosts; in this example, on the 192.168.0 subnet) in the Hosts Allow field under the Security Options.
section. If you need help on how to format the entry, click the Help link to the left of the field. A new web page appears with the pertinent information.

![Samba Configuration Interface]

**FIGURE 16.1** You can use SWAT to easily configure and administer Samba on your system.

![Samba Global Parameters]

**FIGURE 16.2** Configure Samba to allow access from specific hosts or subnets on your LAN.

When finished, click the Commit Changes button to save the global access settings. The next step is to create a Samba user and set the user’s password. Click the Password icon on
the main SWAT page (refer to Figure 16.1). The Server Password Management page opens, as shown in Figure 16.3. Type a new username in the User Name field; then type a password in the New Password and Re-type New Password fields.

![Server Password Management](image)

**NOTE**

You must supply a username of an existing system user, but the password used for Samba access does not have to match the existing user's password.

When finished, click the Add New User button. SWAT then creates the username and password and displays Added user *username* (where *username* is the name you entered). The new Samba user should now be able to gain access to the home directory from any allowed host if the Samba \(\text{smb}\) server is running.

For example, if you have set up Samba on a host named *mini* that has a user named *andrew*, the user can access the home directory on *mini* from any remote host (if allowed by the Globals settings), perhaps by using the *smbclient* command like this:

```
matthew@seymour:-$ smbclient //mini/andrew -U andrew
added interface ip=192.168.0.68 bcast=192.168.0.255 nmask=255.255.255.0
Password:
Domain=[MYGROUP] OS=[Unix] Server=[Samba 3.0.28]
smb: \> pwd
Current directory is \\mini\andrew\n```

![Client/Server Password Management](image)

**FIGURE 16.3** Enter a Samba username and password in the SWAT Password page.
Click the Status icon to view Samba’s status or to start, stop, or restart the server. You can use various buttons on the resulting web page to control the server and view periodic or continuous status updates.

You can also use SWAT to share a Linux directory. First, click the Shares icon in the toolbar at the top of the main Samba page. Then, type a share name in the Create Shares field, and click the Create Shares button. The SWAT Shares page displays the detailed configuration information in a dialog box, as shown in Figure 16.4, providing access to detailed configuration for the new Samba share.

![Figure 16.4 Use the SWAT Shares page to set up sharing of a portion of your Linux file system.](image)

Type the directory name (such as `/music`) you want to share in the Path field under the Base options. Select No or Yes in the Read-Only field under Security options to allow or deny read and write access. Select Yes in the Guest OK option to allow access from other users and specify a hostname, IP address, or subnet in the Hosts Allow field to allow access. Click the Commit Changes button when finished. Remote users can then access the shared volume. This is how a Linux server running Samba can easily mimic shared volumes in a mixed computing environment!

Alternatively, use the `shares-admin` client (from the command line or the Server Settings Samba Server menu item on the System Settings menu). Unlock the tool by clicking the Unlock button, use the Add button to create new shares, and use the Properties button to edit the share’s access options.
Network and Remote Printing with Ubuntu

Chapter 2, “Post-Installation Configuration,” discussed how to set up and configure local printers and the associated print services. This section covers configuring printers for sharing and access across a network.

Offices all over the world benefit from using print servers and shared printers. It is a simple thing to do and can bring real productivity benefits, even in small settings.

Creating Network Printers

Setting up remote printing service involves configuring a print server and then creating a remote printer entry on one or more computers on your network. This section introduces a quick method of enabling printing from one Linux workstation to another Linux computer on a LAN. You also learn about SMB printing using Samba and its utilities. Finally, this section discusses how to configure network-attached printers and use them to print single or multiple documents.

Enabling Network Printing on a LAN

If the computer with an attached printer is using Ubuntu and you want to set up the system for print serving, use the `system-config-printer` client to create a new printer, which is available in the menu at System, Administration, Printing.

First, install any printers you have to the server as discussed in Chapter 2 (Click Add and wait a moment and it is very likely the printer will be detected automatically; it is probably easy enough that you don’t have to look up what is written in the other chapter).

Next, open Server, Settings and enable Publish Shared Printers Connected to This System. Click OK.

Then, right-click any printer’s icon and select Share. That’s it. Most users will not need the information in the rest of this section, even to enable access to CUPS via the web interface.

To enable sharing manually, edit your `/etc/cups/cupsd.conf` file. Look for the section that begins with `<Location />` and modify it so that it reads as follows:

```
<Location />
Order Deny,Allow
Deny From All
Allow From 127.0.0.1
Allow From 192.168.0.*
</Location>
```

This tells CUPS to share your printers across the network 192.168.0.*, for example. Make sure to change this to match your own network settings.

Next you need to look in the same file for the section that starts:

```
Listen localhost:631
```
Modify it to show this:

```
Listen 631
```

This tells CUPS to listen on port 631 for any printer requests.

**Session Message Block Printing**

Printing to an SMB printer requires Samba, along with its utilities such as the `smbclient` and associated `smbprint` printing filter. You can use the Samba software included with Ubuntu to print to a shared printer on a Windows network or set up a printer attached to your system as an SMB printer. This section describes how to create a local printer entry to print to a remote shared printer using SMB.

Setting up an SMB or shared printer is usually accomplished under Windows operating systems through configuration settings using the Control Panel’s Network device. After enabling print sharing, reboot the computer. In the My Computer, Printers folder, right-click the name or icon of the printer you want to share and select Sharing from the pop-up menu. Set the Shared As item, and then enter a descriptive shared name, such as `HP2100`, and a password.

You must enter a shared name and password to configure the printer when running Linux. You also need to know the printer's workgroup name, IP address, and printer name and have the username and password on hand. To find this information, select Start, Settings, Printers; then right-click the shared printer's listing in the Printers window and select Properties from the pop-up window.

You can use CUPS to configure Samba to use your printers by editing the `smb.conf` file.

In the global section enter the following lines, if they are not already there:

```
... 
load printers = yes
printing = cups
printcap name = cups
```

This tells Samba to use CUPS to provide printing services. Next you need to create a new section in the `smb.conf` file at the end of the file, as follows:

```
[printers]
comment = Use this for All Printers
path = /var/spool/samba
browseable = no
public = yes
guest ok = yes
writable = no
printable = yes
printer admin = root, andrew
```
This publishes your printers to the network and allows others to connect to them via Windows clients.

Make sure you restart the Samba service using the command shown earlier to make Samba pick up the changes to the configuration file.

**Using the Common UNIX Printing System GUI**

You can use CUPS to create printer queues, get print server information, and manage queues by launching a browser (such as Firefox) and browsing to http://localhost:631. CUPS provide a web-based administration interface, as shown in Figure 16.5.

![Common UNIX Printing System 1.3.6](image)

**FIGURE 16.5** Use the web-based CUPS administrative interface to configure and manage printing.

If you click the Administration tab in the browser page, you can start configuring your printers, as shown in Figure 16.6.

**Creating a CUPS Printer Entry**

This section provides a short example of creating a Linux printer entry using CUPS’s web-based interface. Use the CUPS interface to create a printer and device queue type (such as local, remote, serial port, or Internet); then you enter a device *uniform resource identifier (URI)*, such as lpd://192.168.2.35/lp, which represents the IP address of a remote UNIX print server and the name of the remote print queue on the server. You also need to specify the model or make of printer and its driver. A Printers page link allows you to print a test page, stop the printing service, manage the local print queue, modify the printer entry, or add another printer.

In the Admin page, click the Add Printer button and then enter a printer name in the Name field (such as lp), a physical location of the printer in the Location field, and a
short note about the printer (such as its type) in the Description field. Figure 16.7 shows a sample entry for an HP 2100 LaserJet.

Click the Continue button. You can then select the type of printer access (local, remote, serial port, or Internet) in the Device page. For example, to configure printing to a local printer, select LPT1 or, for a remote printer, select the LPD/LPR Host or Printer entry.
Again click Continue and select a printer make as requested in the dialog box shown in Figure 16.8.

After you click Continue, you then select the driver by choosing the exact model of your printer from the list provided. Finish by clicking the Add Printer button, and you will be prompted for your username and password (make sure you have admin rights linked to your account) before the printer is actually added to the system. After creating the printer, you can then use the Printer page, as shown in Figure 16.9, to print a test page, stop printing service, manage the local print queue, modify the printer entry, or add another printer.

CUPS offers many additional features and after it is installed, configured, and running, provides transparent traditional UNIX printing support for Ubuntu.

NOTE
To learn more about CUPS and to get a basic overview of the system, browse to www.cups.org/.

Avoiding Printer Support Problems
Troubleshooting printer problems can prove frustrating, especially if you find that your new printer is not working properly with Linux. Keep in mind, however, that nearly all printers on the market today work with Linux. However, some vendors have higher batting averages in the game of supporting Linux. If you care to see a scorecard, browse to www.linuxprinting.org/vendors.html.
All-in-One (Print/Fax/Scan) Devices

Problematic printers, or printing devices that might or might not work with Ubuntu, include multifunction (or all-in-one) printers that combine scanning, faxing, and printing services. You should research any planned purchase and avoid any vendor unwilling to support Linux with drivers or development information.

One shining star in the field of Linux support for multifunction printers is the HP support of the HP OfficeJet Linux driver project at http://hpoj.sourceforge.net/. Printing and scanning are supported on many models, with fax support in development.

Using USB and Legacy Printers

Other problems can arise because of a lack of a printer’s USB vendor and device ID information—a problem shared by some USB scanners under Linux. For information regarding USB printer support, check with the Linux printing folks (at the URL in the start of this section) or with the Linux USB project at www.linux-usb.org/.

Although many newer printers require a universal serial bus (USB) port, excellent support still exists for legacy parallel-port (IEEE-1284) printers with Linux, enabling sites to continue to use older hardware. You can take advantage of Linux workarounds to set up printing even if the host computer does not have a traditional parallel printer port or if you want to use a newer USB printer on an older computer.

For example, to host a parallel-port-based printer on a USB-only computer, attach the printer to the computer using an inexpensive USB-to-parallel converter. USB-to-parallel converters typically provide a Centronics connector; one end of that connector is plugged in to the older printer, and the other end is plugged in to a USB connector. The USB connector is then plugged in to your hub, desktop, or notebook USB port. On the other hand, you can use an add-on PCI card to add USB support for printing (and other devices)
if the legacy computer does not have a built-in USB port. Most PCI USB interface cards add at least two ports, and you can chain devices via a hub.

**RELATED UBUNTU AND LINUX COMMANDS**

The following commands help you manage printing services:

- `accept`—Controls print job access to the CUPS server via the command line
- `cancel`—Cancels a print job from the command line
- `disable`—Control printing from the command line
- `enable`—Controls CUPS printers
- `lp`—Sends a specified file to the printer and allows control of the print service
- `lpc`—Displays the status of printers and print service at the console
- `lpq`—Views print queues (pending print jobs) at the console
- `lprm`—Removes print jobs from the print queue via the command line
- `lpstat`—Displays printer and server status

CHAPTER 17

Apache Web Server Management

This chapter covers the configuration and management of the Apache web server and includes an overview of some of the major components of the server and discussions of text-based and graphical server configuration. You will see how to start, stop, and restart Apache using the command line. The chapter begins with some introductory information and then shows you how to install, configure, and use Apache.

About the Apache Web Server

Apache is the most widely used web server on the Internet today, according to a Netcraft survey of active websites in July 2010, which is shown in Table 17.1 (from http://news.netcraft.com/archives/2010/08/11/august-2010-web-server-survey-4.html).

Note that these statistics do not reflect use on internal networks, known as intranets.

The name Apache appeared during the early development of the software because it was “a patchy” server, made up of patches for the freely available source code of the NCSA HTTPd web server. For a while after the NCSA HTTPd project was discontinued, a number of people wrote a variety of patches for the code, to either fix bugs or add features they wanted. A lot of this code was floating around and people were freely sharing it, but it was completely unmanaged.

After a while, Brian Behlendorf and Cliff Skolnick set up a centralized repository of these patches, and the Apache project was born. The project is still composed of a small
core group of programmers, but anyone is welcome to submit patches to the group for possible inclusion in the code.

</table>

There has been a surge of interest in the Apache project over the past several years, partially buoyed by a new interest in open source on the part of enterprise-level information services. It’s also due in part to crippling security flaws found in Microsoft’s Internet Information Services (IIS); the existence of malicious web task exploits; and operating system and networking vulnerabilities to the now-infamous Code Red, Blaster, and Nimda worms. IBM made an early commitment to support and use Apache as the basis for its web offerings and has dedicated substantial resources to the project because it makes more sense to use an established, proven web server.

In mid-1999, The Apache Software Foundation was incorporated as a nonprofit company. A board of directors, who are elected on an annual basis by the ASF members, oversees the company. This company provides a foundation for several open-source software development projects, including the Apache Web Server project.

**TIP**

You’ll find an overview of Apache in its frequently asked questions (FAQs) at http://httpd.apache.org/docs/2.2/faq/. In addition to extensive online documentation, you’ll also find the complete documentation for Apache in the HTML directory of your Apache server. If you have Apache running on your system, you can access this documentation by looking at http://localhost/manual/index.html.

To determine the precise version of Apache included with your system, use the web server’s `-v` command-line option like this:

```
matthew@seymour:-$ /usr/sbin/apache2 -V
```

The output displays the version number, build date and time, platform, and various options used during the build. You can use the `-v` option to see abbreviated version information.
Installing the Apache Server

You can install Apache through APT or build it yourself from source code. The Apache source builds on just about any UNIX-like operating system and on Win32.

If you are about to install a new version of Apache, you should shut down the old server. Even if it’s unlikely that the old server will interfere with the installation procedure, shutting it down ensures that there will be no problems. If you do not know how to stop Apache, see the “Starting and Stopping Apache” section later in this chapter.

Installing from the Ubuntu repositories

You can install the apache2 package from the Ubuntu software repositories. Updated packages usually contain important bug and security fixes. When an updated version is released, install it as quickly as possible to keep your system secure.

NOTE

Check the Apache site for security reports. Browse to http://httpd.apache.org/security_report.html for links to security vulnerabilities for Apache 1.3, 2.0, and 2.2. Subscribe to a support list or browse through up-to-date archives of all Apache mailing lists at http://httpd.apache.org/mail/ (for various articles) or http://httpd.apache.org/lists.html (for comprehensive and organized archives).

CAUTION

You should be wary of installing experimental packages, and never install them on production servers (that is, servers used in “real life”). Very carefully test the packages beforehand on a host that is not connected to a network!

For more information on installing software from the Ubuntu repositories, see chapter 32, “Managing Software.”

The Apache package installs files in the following directories:

- /etc/apache2—This directory contains the Apache configuration file, apache2.conf.
- /etc/init.d/—The tree under this directory contains the system startup scripts. The Apache package installs a startup script named apache2 for the web server under the /etc/init.d directory. This script, which you can use to start and stop the server from the command line, also automatically starts and stops the server when the computer is halted, started, or rebooted.
- /var/www—The package installs the default server icons, Common Gateway Interface (CGI) programs, and HTML files in this location. If you want to keep web content elsewhere, you can do so by making the appropriate changes in the server configuration files.
If you've installed the apache2-doc package, you'll find a copy of the Apache documentation in HTML format here. You can access it with a web browser by going to http://localhost/manual/.

Ubuntu's Apache package also contains manual pages, which are placed underneath this directory. For example, the apache2 man page is in Section 8 of the man directory.

The executable programs are placed in this directory. This includes the server executable itself, as well as various utilities.

Some of the utilities from the Apache package are placed here—for example, the htpasswd program, which is used for generating authentication password files.

The server log files are placed in this directory. By default, there are two important log files (among several others): access_log and error_log. However, you can define any number of custom logs containing a variety of information. See the section “Logging,” later in this chapter, for more detail.

When Apache is being run, it also creates the file apache2.pid, containing the process ID of Apache’s parent process in the /var/run/ directory.

NOTE

If you are upgrading to a newer version of Apache, APT does not write over your current configuration files.

Building the Source Yourself

You can download the source directly from www.apache.org/. The latest version at the time of this writing (2.2.16) is a 6MB compressed tape archive, and the latest pre-2.0 version of Apache is 1.3.42. Although many sites continue to use the older version (for script and other compatibility reasons), most sites are migrating to or are starting out using the latest stable version.

After you have the tar file, you must unroll it in a temporary directory, such as /tmp. Unrolling this tar file creates a directory called apache_version_number, where version_number is the version you have downloaded (for example, apache_1.3.34).

There are two ways to compile the source—the old, familiar way (at least, to those of us who have been using Apache for many years) by editing Makefile templates, and the new, easy way using a configure script. You will first see how to build Apache from source the easy way. The configure script offers a way to have the source software automatically configured according to your system. However, manually editing the configuration files
before building and installing Apache provides more control over where the software is installed and which capabilities or features are built in to Apache.

TIP

As with many software packages distributed in source code form for Linux and other UNIX-like operating systems, extracting the source code results in a directory that contains a README and an INSTALL file. Be sure to peruse the INSTALL file before attempting to build and install the software.

Using ./configure to Build Apache

To build Apache the easy way, run the ./configure script in the directory just created. You can provide it with a —prefix argument to install it in a directory other than the default, which is /usr/local/apache/. Use this command:

```
matthew~/.usr/src/apache2$ sudo ./configure —prefix=/preferred/directory/
```

This generates the Makefile that is used to compile the server code.

Next, type make to compile the server code. After the compilation is complete, type make install as root to install the server. You can now configure the server via the configuration files. See the “Runtime Server Configuration Settings” section for more information.

TIP

A safer way to install a new version of Apache from source is to use the ln command to create symbolic links of the existing file locations (listed in the “Installing with APT” section earlier in this chapter) to the new locations of the files. This method is safer because the default install locations are different from those used when the package installs the files. Failure to use this installation method could result in your web server process not being started automatically at system startup.

Another safe way to install a new version of Apache is to first back up any important configuration directories and files (such as /etc/apache2) and then use the apt-get command to remove the server. You can then install and test your new version and, if needed, easily restore your original server and settings.

It is strongly recommended that you use Ubuntu’s version of Apache until you really know what happens at system startup. No “uninstall” option is available when installing Apache from source!

Apache File Locations After a Build and Install

Files are placed in various subdirectories of /usr/local/apache (or whatever directory you specified with the —prefix parameter) if you build the server from source.
The following is a list of the directories used by Apache, as well as brief comments on their usage:

- `/usr/local/apache/conf`—This contains several subdirectories and the Apache configuration file, `httpd.conf`. Debian-based systems such as Ubuntu often rename this to `apache2.conf`, so your mileage may vary. See the section “Editing `apache2.conf`” later in this chapter to learn more about configuration files.

- `/usr/local/apache`—The `cgi-bin`, `icons`, and `htdocs` subdirectories contain the CGI programs, standard icons, and default HTML documents, respectively.

- `/usr/local/apache/bin`—The executable programs are placed in this directory.

- `/usr/local/apache/logs`—The server log files are placed in this directory. By default, there are two log files—`access_log` and `error_log`—but you can define any number of custom logs containing a variety of information (see the “Logging” section later in this chapter). The default location for Apache’s logs as installed by Ubuntu is `/var/log/apache2`.

---

**A QUICK GUIDE TO GETTING STARTED WITH APACHE**

Setting up, testing a web page, and starting Apache using Ubuntu can be accomplished in just a few steps. First, make sure that Apache is installed on your system. Either select it during installation or install the server, and related package files (see Chapter 32 if you need to install the server software).

Next, set up a home page for your system by editing (as root) the file named `index.html` under the `/var/www` directory on your system. Make a backup copy of the original page or `www` directory before you begin so you can restore your web server to its default state if necessary.

Start Apache through the Services window (under System, Administration from the menu bar), making sure to enable “Web Server”.

You can also use the `apache2` script under the `/etc/init.d/` directory, like this:

```
matthew@seymour:~$ sudo /etc/init.d/apache2 start
```

You can then check your home page by running a favorite browser and using localhost, your system’s hostname, or its Internet Protocol (IP) address in the URL. For example, with the links text browser, use a command line like this:

```
matthew@seymour:~$ links http://localhost/
```

For security reasons, you should not start and run Apache as root if your host is connected to the Internet or a company intranet. Fortunately, Apache is set to run as the user and group `www-data` no matter how it is started (by the User and Group settings in `/etc/apache2/apache2.conf`). Despite this safe default, Apache should be started and managed by the user named `www-data`, defined in `/etc/passwd` as:

```
www-data:x:33:33:www-data:/var/www:/bin/sh
```

After you are satisfied with your website, use the Services configuration dialog to ensure that Apache is started.
Starting and Stopping Apache

At this point, you have installed your Apache server with its default configuration. Ubuntu provides a default home page named index.html as a test under the /var/www/ directory. The proper way to run Apache is to set system initialization to have the server run after booting, network configuration, and any firewall configuration. See Chapter 11, “Automating Tasks,” for more information about how Ubuntu boots.

It is time to start it up for the first time. The following sections show how to either start and stop Apache or configure Ubuntu to start or not start Apache when booting.

Starting the Apache Server Manually

You can start Apache from the command line of a text-based console or X terminal window, and you must have root permission to do so. The server daemon, apache2, recognizes several command-line options you can use to set some defaults, such as specifying where apache2 reads its configuration directives. The Apache apache2 executable also understands other options that enable you to selectively use parts of its configuration file, specify a different location of the actual server and supporting files, use a different configuration file (perhaps for testing), and save startup errors to a specific log. The -v option causes Apache to print its development version and quit. The -V option shows all the settings that were in effect when the server was compiled.

The -h option prints the following usage information for the server:

```bash
matthew@seymour:~$ apache2 -h
Usage: apache2 [-D name] [-d directory] [-f file]
       [-C "directive"] [-c "directive"]
       [-k start|restart|graceful|stop]
Options:
  -D name           : define a name for use in <IfDefine name> directives
  -d directory      : specify an alternate initial ServerRoot
  -f file           : specify an alternate ServerConfigFile
  -C "directive"    : process directive before reading config files
  -c "directive"    : process directive after reading config files
  -e level          : show startup errors of level (see LogLevel)
  -E file           : log startup errors to file
  -v                : show version number
  -V                : show compile settings
  -h                : list available command line options (this page)
  -l                : list compiled in modules
  -L                : list available configuration directives
  -t -D DUMP_VHOSTS : show parsed settings (currently only vhost settings)
  -t                : run syntax check for config files
```

Other options include listing Apache’s static modules, or special, built-in independent parts of the server, along with options that can be used with the modules. These options are
called configuration directives and are commands that control how a static module works. Note that Apache also includes nearly 50 dynamic modules, or software portions of the server that can be optionally loaded and used while the server is running.

The `-t` option is used to check your configuration files. It’s a good idea to run this check before restarting your server, especially if you’ve made changes to your configuration files. Such tests are important because a configuration file error can result in your server shutting down when you try to restart it. There is a bug in the internal username settings for Apache2 in Ubuntu that gives you this error if you enter:

```bash
matthew@seymour:~$ sudo apache2 -t
apache2: bad user name ${APACHE_RUN_USER}
```

If this happens to you, enter the command this way to force the command to use the expected username settings and you will get the proper output:

```bash
matthew@seymour:~$ sudo APACHE_RUN_USER=www-data APACHE_RUN_GROUP=www-data apache2 -t
```

**NOTE**

When you build and install Apache from source, start the server manually from the command line through `sudo` (such as when testing). You do this for two reasons:

- The standalone server uses the default HTTP port (port 80), and only the super-user can bind to Internet ports that are lower than 1024.
- Only processes owned by root can change their UID and GID as specified by Apache’s User and Group directives. If you start the server under another UID, it runs with the permissions of the user starting the process.

Note that although some of the following examples show how to start the server through `sudo`, you should do so only for testing after building and installing Apache.

### Using `/etc/init.d/apache2`

Ubuntu uses the scripts in the `/etc/init.d` directory to control the startup and shutdown of various services, including the Apache web server. The main script installed for the Apache web server is `/etc/init.d/apache2`, although the actual work is done by the `apache2ctl` shell script included with Apache.

**NOTE**

`/etc/init.d/apache2` is a shell script and is not the same as the Apache server located in `/usr/sbin`. That is, `/usr/sbin/apache2` is the program executable file (the server); `/etc/init.d/apache2` is a shell script that uses another shell script, `apache2ctl`, to control the server. See Chapter 11, “Automating Tasks,” for a description of some service scripts under `/etc/init.d` and how the scripts are used to manage services such as `apache2`. 

Download from www.eBookTM.com
You can use the `/etc/init.d/apache2` script to control the web server. Here are some of the most common options to include with the command:

- **start**—The system uses this option to start the web server during bootup. You, through sudo, can also use this script to start the server.
- **stop**—The system uses this option to stop the server gracefully. You should use this script, rather than the `kill` command, to stop the server.
- **reload**—You can use this option to send the `HUP` signal to the `apache2` server to have it reread the configuration files after modification.
- **restart**—This option is a convenient way to stop and then immediately start the web server. If the `apache2` server isn’t running, it is started.
- **status**—This option indicates whether the server is running; if it is, it provides the PID for each instance of the server.

For example, to check on the status of your server, use the command:

```
matthew@seymour:~$ sudo /etc/init.d/apache2 status
```

This prints the following on my machine. Your PID(s) will be different:

```
apache2 (pid 4743) is running...
```

This indicates that the web server is running.

In addition to the previous options, the `apache2` script also offers these features:

- **help**—Prints a list of valid options to the `apache2` script (which are passed onto the server as if called from the command line).
- **force-reload**—Restarts the server while forcing it to reload configuration files.

**TIP**

Use the `force-reload` option if you are making many changes to the various server configuration files. This saves time when you are stopping and starting the server by having the system simply reread the configuration files.

---

**Runtime Server Configuration Settings**

At this point, the Apache server will run, but perhaps you want to change a behavior, such as the default location of your website’s files. This section talks about the basics of configuring the server to work the way you want it to work.

Runtime configurations are stored in just one file—`apache2.conf`, which is found under the `/etc/apache2` directory. This configuration file can be used to control the default behavior of Apache, such as the web server’s base configuration directory (`/etc/apache2`), the name of the server’s process identification (PID) file (`/var/run/apache2.pid`), or its response timeout (300 seconds). Apache reads the data from the configuration file when
started (or restarted). You can also cause Apache to reload configuration information with the command `/etc/init.d/apache2 reload`, which is necessary after making changes to its configuration file. (You learned how to accomplish this in the earlier section, “Starting and Stopping Apache.”)

### Runtime Configuration Directives

You perform runtime configuration of your server with configuration directives, which are commands that set options for the `apache2` daemon. The directives are used to tell the server about various options you want to enable, such as the location of files important to the server configuration and operation. Apache supports nearly 300 configuration directives using the following syntax:

```
directive option option...
```

Each directive is specified on a single line. See the following sections for some sample directives and how to use them. Some directives only set a value such as a filename, whereas others enable you to specify various options. Some special directives, called sections, look like HTML tags. Section directives are surrounded by angle brackets, such as `<directive>`. Sections usually enclose a group of directives that apply only to the directory specified in the section:

```
<Directory somedir/in/your/tree>
  directive option option
  directive option option
</Directory>
```

All sections are closed with a matching section tag that looks like this: `</directive>`. Note that section tags, like any other directives, are specified one per line.

---

**TIP**

Apache is configured with an alias that lets you view the documentation installed in `/usr/share/doc` using your web browser at localhost/manual. After installing and starting Apache, you’ll find an index of directives at http://localhost/manual/mod/directives.html.

---

### Editing `apache2.conf`

Most of the default settings in the config file are okay to keep, particularly if you’ve installed the server in a default location and aren’t doing anything unusual on your server. In general, if you do not understand what a particular directive is for, you should leave it set to the default value.

The following sections describe some of the configuration file settings you _might_ want to change concerning operation of your server.
ServerRoot
The ServerRoot directive sets the absolute path to your server directory. This directive tells the server where to find all the resources and configuration files. Many of these resources are specified in the configuration files relative to the ServerRoot directory.

Your ServerRoot directive should be set to /etc/apache2 if you installed the Ubuntu package or /usr/local/apache (or whatever directory you chose when you compiled Apache) if you installed from the source. This is commented out in the file, but apache2 -V shows that this default has been compiled into the package.

Listen
The Listen directive is actually in a file called ports.conf that is included from apache2.conf and indicates on which port you want your server to run. By default, this is set to 80, which is the standard HTTP port number. You might want to run your server on another port—for example, when running a test server that you don’t want people to find by accident. Do not confuse this with real security! See the “File System Authentication and Access Control” section for more information about how to secure parts of your web server.

User and Group
The User and Group directives should be set to the UID and group ID (GID) the server will use to process requests.

In Ubuntu, set these configurations to a user with few or no privileges. In this case, they’re set to user www-data and group www-data—a user defined specifically to run Apache. If you want to use a different UID or GID, be aware that the server will run with the permissions of the user and group set here. That means in the event of a security breach, whether on the server or (more likely) in your own CGI programs, those programs will run with the assigned UID. If the server runs as root or some other privileged user, someone can exploit the security holes and do nasty things to your site. Always think in terms of the specified user running a command such as rm -rf / because that would wipe all files from your system. That should convince you that leaving apache as a user with no privileges is probably a good thing.

Instead of specifying the User and Group directives using names, you can specify them using the UID and GID numbers. If you use numbers, be sure that the numbers you specify correspond to the user and group you want and that they’re preceded by the pound (#) symbol.

Here's how these directives look if specified by name:

User apache
Group apache

Here's the same specification by UID and GID:

User #48
Group #48
TIP

If you find a user on your system (other than root) with a UID and GID of 0, your system has been compromised by a malicious user.

ServerAdmin
The ServerAdmin directive should be set to the address of the webmaster managing the server. This address should be a valid email address or alias, such as webmaster@gnulix.org, because this address is returned to a visitor when a problem occurs on the server.

ServerName
The ServerName directive sets the hostname the server will return. Set it to a fully qualified domain name (FQDN). For example, set it to www.your.domain rather than simply www. This is particularly important if this machine will be accessible from the Internet rather than just on your local network.

You don’t need to set this unless you want a name other than the machine’s canonical name returned. If this value isn’t set, the server will figure out the name by itself and set it to its canonical name. However, you might want the server to return a friendlier address, such as www.your.domain. Whatever you do, ServerName should be a real domain name service (DNS) name for your network. If you’re administering your own DNS, remember to add an alias for your host. If someone else manages the DNS for you, ask that person to set this name for you.

DocumentRoot
Set this directive to the absolute path of your document tree, which is the top directory from which Apache will serve files. By default, it’s set to /var/www/. If you built the source code yourself, DocumentRoot is set to /usr/local/apache/htdocs (if you did not choose another directory when you compiled Apache).

UserDir
The UserDir directive disables or enables and defines the directory (relative to a local user’s home directory) where that user can put public HTML documents. It is relative because each user has her own HTML directory. This setting is disabled by default but can be enabled to store user web content under any directory.

The default setting for this directive, if enabled, is public_html. Each user can create a directory called public_html under her home directory, and HTML documents placed in that directory are available as http://servername/~username, where username is the user-name of the particular user.

DirectoryIndex
The DirectoryIndex directive indicates which file should be served as the index for a directory, such as which file should be served if the URL http://servername/_SomeDirectory/ is requested.
It is often useful to put a list of files here so that if `index.html` (the default value) isn’t found, another file can be served instead. The most useful application of this is to have a CGI program run as the default action in a directory. If you have users who make their web pages on Windows, you might want to add `index.htm` as well. In that case, the directive would look like `DirectoryIndex index.html index.cgi index.htm`.

**Apache Multiprocessing Modules**

Apache Version 2.0 and greater now uses a new internal architecture supporting multiprocessing modules (MPMs). These modules are used by the server for a variety of tasks, such as network and process management, and are compiled into Apache. MPMs enable Apache to work much better on a wider variety of computer platforms, and they can help improve server stability, compatibility, and scalability.

Apache can use only one MPM at any time. These modules are different from the base set included with Apache (see the “Apache Modules” section later in this chapter) but are used to implement settings, limits, or other server actions. Each module in turn supports numerous additional settings, called *directives*, which further refine server operation.

The internal MPM modules relevant for Linux include:

- `mpm_common`—A set of 20 directives common to all MPM modules
- `prefork`—A nonthreaded, preforking web server that works similar to earlier (1.3) versions of Apache
- `worker`—Provides a hybrid multiprocess multithreaded server

MPM enables Apache to be used on equipment with fewer resources yet still handle massive numbers of hits and provide stable service. The *worker* module provides directives to control how many simultaneous connections your server can handle.

**NOTE**

Other MPMs are available for Apache related to other platforms, such as `mpm_netware` for NetWare hosts and `mpm_winnt` for NT platforms. An MPM named `perchild`, which provides user ID assignment to selected daemon processes, is under development. For more information, browse to the Apache Software Foundation’s home page at www.apache.org.

**Using .htaccess Configuration Files**

Apache also supports special configuration files, known as `.htaccess` files. Almost any directive that appears in `apache2.conf` can appear in an `.htaccess` file. This file, specified in the *AccessFileName* directive in `apache2.conf` sets configurations on a per-directory (usually in a user directory) basis. As the system administrator, you can specify both the name of this file and which of the server configurations can be overridden by the contents of this file. This is especially useful for sites in which there are multiple content providers and you want to control what these people can do with their space.
To limit which server configurations the .htaccess files can override, use the AllowOverride directive. AllowOverride can be set globally or per directory. For example, in your apache2.conf file, you could use the following:

```apache
# Each directory to which Apache has access can be configured with respect
# to which services and features are allowed and/or disabled in that
# directory (and its subdirectories).
#
# First, we configure the "default" to be a very restrictive set of
# permissions.
#
<Directory/>
  Options FollowSymLinks
  AllowOverride None
</Directory>
```

### Options Directives

To configure which configuration options are available to Apache by default, you must use the Options directive. Options can be None; All; or any combination of Indexes, Includes, FollowSymLinks, ExecCGI, and MultiViews. MultiViews are not included in All and must be specified explicitly. These options are explained in Table 17.2.

#### TABLE 17.2 Switches Used by the Options Directive

<table>
<thead>
<tr>
<th>Switch</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None of the available options are enabled for this directory.</td>
</tr>
<tr>
<td>Indexes</td>
<td>In the absence of an index.html file or another DirectoryIndex file, a listing of the files in the directory is generated as an HTML page for display to the user.</td>
</tr>
<tr>
<td>Includes</td>
<td>Server-side includes (SSIs) are permitted in this directory. This can also be written as IncludesNoExec if you want to allow includes but don't want to allow the exec option in them. For security reasons, this is usually a good idea in directories over which you don't have complete control, such as UserDir directories.</td>
</tr>
<tr>
<td>FollowSymLinks</td>
<td>Allows access to directories that are symbolically linked to a document directory. You should never set this globally for the whole server and only rarely for individual directories. This option is a potential security risk because it allows web users to escape from the document directory and could potentially allow them access to portions of your file system where you really don't want people poking around.</td>
</tr>
<tr>
<td>ExecCGI</td>
<td>CGI programs are permitted in this directory, even if it is not a directory defined in the ScriptAlias directive.</td>
</tr>
</tbody>
</table>
NOTE
These directives also affect all subdirectories of the specified directory.

AllowOverrides Directives
The AllowOverrides directives specify which configuration options .htaccess files can override. You can set this directive individually for each directory. For example, you can have different standards about what can be overridden in the main document root and in UserDir directories.

This capability is particularly useful for user directories, where the user does not have access to the main server configuration files.

AllowOverrides can be set to All or any combination of Options, FileInfo, AuthConfig, and Limit. These options are explained in Table 17.3.

<table>
<thead>
<tr>
<th>Switch</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Options</td>
<td>The .htaccess file can add options not listed in the Options directive for this directory.</td>
</tr>
<tr>
<td>FileInfo</td>
<td>The .htaccess file can include directives for modifying document type information.</td>
</tr>
<tr>
<td>AuthConfig</td>
<td>The .htaccess file might contain authorization directives.</td>
</tr>
<tr>
<td>Limit</td>
<td>The .htaccess file might contain allow, deny, and order directives.</td>
</tr>
</tbody>
</table>

File System Authentication and Access Control
You’re likely to include material on your website that isn’t supposed to be available to the public. You must be able to lock out this material from public access and provide designated users with the means to unlock the material. Apache provides two methods for accomplishing this type of access: authentication and authorization. You can use different criteria to control access to sections of your website, including checking the client’s IP address or hostname, or requiring a username and password. This section briefly covers some of these methods.
CAUTION
Allowing individual users to put web content on your server poses several important security risks. If you’re operating a web server on the Internet rather than on a private network, you should read the WWW Security FAQ at www.w3.org/Security/Faq/www-security-faq.html.

Restricting Access with allow and deny

One of the simplest ways to limit access to website material is to restrict access to a specific group of users, based on IP addresses or hostnames. Apache uses the allow and deny directives to accomplish this.

Both directives take an address expression as a parameter. The following list provides the possible values and use of the address expression:

- All can be used to affect all hosts.
- A hostname or domain name, which can either be a partially or a fully qualified domain name; for example, test.gnulix.org or gnulix.org.
- An IP address, which can be either full or partial; for example, 212.85.67 or 212.85.67.66.
- A network/netmask pair, such as 212.85.67.0/255.255.255.0.
- A network address specified in classless inter-domain routing (CIDR) format; for example, 212.85.67.0/24. This is the CIDR notation for the same network and netmask that were used in the previous example.

If you have the choice, it is preferable to base your access control on IP addresses rather than hostnames. Doing so results in faster performance because no name lookup is necessary—the IP address of the client is included with each request.

You also can use allow and deny to provide or deny access to website material based on the presence or absence of a specific environment variable. For example, the following statement denies access to a request with a context that contains an environment variable named NOACCESS:

```
deny from env=NOACCESS
```

The default behavior of Apache is to apply all the deny directives first and then check the allow directives. If you want to change this order, you can use the order statement. Apache might interpret this statement in three different ways:

- **Order deny,allow**—The deny directives are evaluated before the allow directives. If a host is not specifically denied access, it is allowed to access the resource. This is the default ordering if nothing else is specified.
- **Order allow,deny**—All allow directives are evaluated before deny directives. If a host is not specifically allowed access, it is denied access to the resource.
Order mutual-failure—Only hosts that are specified in an allow directive and at the same time do not appear in a deny directive are allowed access. If a host does not appear in either directive, it is not granted access.

Consider this example. Suppose you want to allow only persons from within your own domain to access the server-status resource on your web. If your domain were named gnulix.org, you could add these lines to your configuration file:

```
<Location /server-status>
  SetHandler server-status
  Order deny,allow
  Deny from all
  Allow from gnulix.org
</Location>
```

**Authentication**

Authentication is the process of ensuring that visitors really are who they claim to be. You can configure Apache to allow access to specific areas of web content only to clients who can authenticate their identity. There are several methods of authentication in Apache; Basic Authentication is the most common (and the method discussed in this chapter).

Under Basic Authentication, Apache requires a user to supply a username and a password to access the protected resources. Apache then verifies that the user is allowed to access the resource in question. If the username is acceptable, Apache verifies the password. If the password also checks out, the user is authorized and Apache serves the request.

HTTP is a stateless protocol; each request sent to the server and each response is handled individually, and not in an intelligent fashion. Therefore, the authentication information must be included with each request. That means each request to a password-protected area is larger and therefore somewhat slower. To avoid unnecessary system use and delays, protect only those areas of your website that absolutely need protection.

To use Basic Authentication, you need a file that lists which users are allowed to access the resources. This file is composed of a plain text list containing name and password pairs. It looks very much like the /etc/passwd user file of your Linux system.

**CAUTION**

Do not use /etc/passwd as a user list for authentication. When you’re using Basic Authentication, passwords and usernames are sent as base64-encoded text from the client to the server—which is just as readable as plain text. The username and password are included in each request that is sent to the server. So, anyone who might be snooping on Net traffic would be able to get this information!
To create a user file for Apache, use the htpasswd command. This is included with the Apache package. If you installed using the packages, it is in /usr/bin. Running htpasswd without any options produces the following output:

Usage:

    htpasswd [-cmdps] passwordfile username
    htpasswd -b[cmdps] passwordfile username password
    htpasswd -n[mdps] username
    htpasswd -nb[mdps] username password

- c  Create a new file.
- n  Don't update file; display results on stdout.
- m  Force MD5 encryption of the password.
- d  Force CRYPT encryption of the password (default).
- p  Do not encrypt the password (plaintext).
- s  Force SHA encryption of the password.
- b  Use the password from the command line rather than prompting for it.
- D  Delete the specified user.

On Windows, TPF and NetWare systems the '-m' flag is used by default. On all other systems, the '-p' flag will probably not work.

As you can see, it isn't a very difficult command to use. For example, to create a new user file named gnulixusers with a user named wsb, you need to do something like this:

    sudo htpasswd -c gnulixusers wsb

You would then be prompted for a password for the user. To add more users, you would repeat the same procedure, only omitting the -c flag.

You can also create user group files. The format of these files is similar to that of /etc/groups. On each line, enter the group name, followed by a colon, and then list all users, with each user separated by spaces. For example, an entry in a user group file might look like this:

    gnulixusers: wsb pgj jp ajje nadia rkr hak

Now that you know how to create a user file, it's time to look at how Apache might use this to protect web resources.

To point Apache to the user file, use the AuthUserFile directive. AuthUserFile takes the file path to the user file as its parameter. If the file path is not absolute—that is, beginning with a /—it is assumed that the path is relative to the ServerRoot. Using the AuthGroupFile directive, you can specify a group file in the same manner.

Next, use the AuthType directive to set the type of authentication to be used for this resource. Here, the type is set to Basic.

Now you need to decide to which realm the resource will belong. Realms are used to group different resources that will share the same users for authorization. A realm can
File System Authentication and Access Control consist of just about any string. The realm is shown in the Authentication dialog box on the user’s web browser. Therefore, you should set the realm string to something informative. The realm is defined with the `AuthName` directive.

Finally, state which type of user is authorized to use the resource. You do this with the `require` directive. The three ways to use this directive are as follows:

- If you specify `valid-user` as an option, any user in the user file is allowed to access the resource (that is, provided she also enters the correct password).
- You can specify a list of users who are allowed access with the `users` option.
- You can specify a list of groups with the `group` option. Entries in the group list, as well as the user list, are separated by a space.

Returning to the `server-status` example you saw earlier, instead of letting users access the `server-status` resource based on hostname, you can require the users to be authenticated to access the resource. You can do so with the following entry in the configuration file:

```latex
<Location /server-status>
  SetHandler server-status
  AuthType Basic
  AuthName "Server status"
  AuthUserFile "gnulixusers"
  Require valid-user
</Location>
```

**Final Words on Access Control**

If you have host-based as well as user-based access protection on a resource, the default behavior of Apache is to require the requester to satisfy both controls. But assume that you want to mix host-based and user-based protection and allow access to a resource if either method succeeds. You can do so using the `satisfy` directive. You can set the `satisfy` directive to `All` (this is the default) or `Any`. When set to `All`, all access control methods must be satisfied before the resource is served. If `satisfy` is set to `Any`, the resource is served if any access condition is met.

Here’s another access control example, again using the previous `server-status` example. This time, you combine access methods so all users from the `gnulix` domain are allowed access and those from outside the domain must identify themselves before gaining access. You can do so with the following:

```latex
<Location /server-status>
  SetHandler server-status
  Order deny,allow
  Deny from all
  Allow from gnulix.org
  AuthType Basic
  AuthName "Server status"
</Location>
```
AuthUserFile "gnulixusers"
Require valid-user
Satisfy Any

There are more ways to protect material on your web server, but the methods discussed here should get you started and will probably be more than adequate for most circumstances. Look to Apache's online documentation for more examples of how to secure areas of your site.

Apache Modules

The Apache core does relatively little; Apache gains its functionality from modules. Each module solves a well-defined problem by adding necessary features. By adding or removing modules to supply the functionality you want Apache to have, you can tailor Apache server to suit your exact needs.

Nearly 70 core modules are included with the basic Apache server. Many more are available from other developers. The Apache Module Registry is a repository for add-on modules for Apache, and it can be found at http://modules.apache.org/. The modules are stored in the /usr/lib/apache2/modules directory (your list might look different):

- httpd.exp
- mod_actions.so
- mod_alias.so
- mod_asis.so
- mod_auth_basic.so
- mod_auth_digest.so
- mod_authn_alias.so
- mod_authn_anon.so
- mod_authn_dbd.so
- mod_authn_dbm.so
- mod_authn_default.so
- mod_authn_file.so
- mod_authnldap.so
- mod_authz_default.so
- mod_authz_groupfile.so
- mod_authz_host.so
- mod_authz_owner.so
- mod_authz_user.so
- mod_autoindex.so
- mod_cache.so
- mod_cgi.so
- mod_charset_lite.so
- mod_dav_fs.so
- mod_dav_lock.so
- mod_dav.so
- mod_deflate.so
- mod_dire.so
- mod_disk_cache.so
- mod_dumpio.so
- mod_env.so
- mod_expires.so
- mod_ext_filter.so
- mod_file_cache.so
- mod_filter.so
- mod_headers.so
- mod_ident.so
- mod_imagemap.so
- mod_include.so
- mod_info.so
- mod_ldap.so
- mod_mime_magic.so
- mod_mime.so
- mod_negotiation.so
- mod_proxy_ajp.so
- mod_proxy_balancer.so
- mod_proxy_connect.so
- mod_proxy_ftp.so
- mod_proxy_http.so
- mod_proxy_scgi.so
- mod_proxy.so
- mod_reqtimeout.so
- mod_rewrite.so
- mod_setenvif.so
- mod_ssl.so
- mod_status.so
- mod_substitute.so
- mod_suexec.so
- mod_unique_id.so
- mod_userdir.so
- mod_usertrack.so
Each module adds new directives that can be used in your configuration files. As you might guess, there are far too many extra commands, switches, and options to describe them all in this chapter. The following sections briefly describe a subset of those modules available with Ubuntu’s Apache installation.

To enable a module, use this command:
```
matthew@seymour:~$ sudo a2enmod module_name
```

To disable a module, use this:
```
matthew@seymour:~$ sudo a2dismod module_name
```

Note that these want the actual name of the module, not the filename, for example `mod_version.so` is the filename, but `version` is the name of the module. You have to know the name of the module to use either command, but in most cases it is as simple as the difference in this example. Also, once you run either command, you need to restart Apache2 to activate the new configuration:
```
matthew@seymour:~$ sudo /etc/init.d/apache2 restart
```

**mod_access**

`mod_access` controls access to areas on your web server based on IP addresses, hostnames, or environment variables. For example, you might want to allow anyone from within your own domain to access certain areas of your web. See the “File System Authentication and Access Control” section for more information.

**mod_alias**

`mod_alias` manipulates the URLs of incoming HTTP requests, such as redirecting a client request to another URL. It also can map a part of the file system into your web hierarchy. For example, the following fetches contents from the `/home/wsb/graphics` directory for any URL that starts with `/images/`:

```
Alias /images/ /home/wsb/graphics/
```

This is done without the client knowing anything about it. If you use a redirection, the client is instructed to go to another URL to find the requested content. More advanced URL manipulation can be accomplished with `mod_rewrite`.

**mod_asis**

`mod_asis` is used to specify, in fine detail, all the information to be included in a response. This completely bypasses any headers Apache might have otherwise added to the response. All files with an `.asis` extension are sent straight to the client without any changes.
As a short example of the use of mod_asis, assume you've moved content from one location to another on your site. Now you must inform people who try to access this resource that it has moved, as well as automatically redirect them to the new location. To provide this information and redirection, you can add the following code to a file with a .asis extension:

```html
<HTML>
  <HEAD>
    <TITLE>We've moved...</TITLE>
  </HEAD>
  <BODY>
    <P>We've moved the old stuff and now you'll find it at:</P>
    <A HREF="http://gnulix.org/newstuff/">New stuff</A>!
  </BODY>
</HTML>
```

mod_auth

mod_auth uses a simple user authentication scheme, referred to as Basic Authentication, which is based on storing usernames and encrypted passwords in a text file. This file looks very much like UNIX’s /etc/passwd file and is created with the htpasswd command. See the “File System Authentication and Access Control” section earlier in this chapter for more information about this subject.

mod_auth_anon

The mod_auth_anon module provides anonymous authentication similar to that of anonymous FTP. The module enables you to define user IDs of those who are to be handled as guest users. When such a user tries to log on, he is prompted to enter his email address as his password. You can have Apache check the password to ensure that it’s a (more or less) proper email address. Basically, it ensures that the password contains an @ character and at least one . character.

mod_auth_dbm

mod_auth_dbm uses Berkeley DB files instead of text for user authentication files.

mod_auth_digest

An extension of the basic mod_auth module, instead of sending the user information in plain text, mod_auth_digest is sent via the MD5 Digest Authentication process. This authentication scheme is defined in RFC 2617. Compared to using Basic Authentication, this is a much more secure way of sending user data over the Internet. Unfortunately, not all web browsers support this authentication scheme.
To create password files for use with `mod_auth_dbm`, you must use the `htdigest` utility. It has more or less the same functionality as the `htpasswd` utility. See the man page of `htdigest` for further information.

**mod_autoindex**

The `mod_autoindex` module dynamically creates a file list for directory indexing. The list is rendered in a user-friendly manner similar to those lists provided by FTP’s built-in `ls` command.

**mod_cgi**

`mod_cgi` allows execution of CGI programs on your server. CGI programs are executable files residing in the `/var/www/cgi-bin` directory and are used to dynamically generate data (usually HTML) for the remote browser when requested.

**mod_dir and mod_env**

The `mod_dir` module is used to determine which files are returned automatically when a user tries to access a directory. The default is `index.html`. If you have users who create web pages on Windows systems, you should also include `index.htm`, like this:

```
DirectoryIndex index.html index.htm
```

`mod_env` controls how environment variables are passed to CGI and SSI scripts.

**mod_expires**

`mod_expires` is used to add an expiration date to content on your site by adding an `Expires` header to the HTTP response. Web browsers or cache servers won’t cache expired content.

**mod_headers**

`mod_headers` is used to manipulate the HTTP headers of your server’s responses. You can replace, add, merge, or delete headers as you see fit. The module supplies a `Header` directive for this. Ordering of the `Header` directive is important. A `set` followed by an `unset` for the same HTTP header removes the header altogether. You can place `Header` directives almost anywhere within your configuration files. These directives are processed in the following order:

1. Core server
2. Virtual host
3. `<Directory>` and `.htaccess` files

```
<Location>
<Files>
```
mod_include

mod_include enables the use of server-side includes on your server, which were quite popular before PHP took over this part of the market.

mod_info and mod_log_config

mod_info provides comprehensive information about your server’s configuration. For example, it displays all the installed modules, as well as all the directives used in its configuration files.

mod_log_config defines how your log files should look. See the “Logging” section for further information about this subject.

mod_mime and mod_mime_magic

The mod_mime module tries to determine the MIME type of files from their extensions. The mod_mime_magic module tries to determine the MIME type of files by examining portions of their content.

mod_negotiation

Using the mod_negotiation module, you can select one of several document versions that best suits the client’s capabilities. There are several options to select which criteria to use in the negotiation process. You can, for example, choose among different languages, graphics file formats, and compression methods.

mod_proxy

mod_proxy implements proxy and caching capabilities for an Apache server. It can proxy and cache FTP, CONNECT, HTTP/0.9, and HTTP/1.0 requests. This isn’t an ideal solution for sites that have a large number of users and therefore have high proxy and cache requirements. However, it’s more than adequate for a small number of users.

mod_rewrite

mod_rewrite is the Swiss army knife of URL manipulation. It enables you to perform any imaginable manipulation of URLs using powerful regular expressions. It provides rewrites, redirection, proxying, and so on. There is very little that you can’t accomplish using this module.

TIP

See http://localhost/manual/misc/rewriteguide.html for a cookbook that gives you an in-depth explanation of what the mod_rewrite module is capable of.
**mod_setenvif**

*mod_setenvif* allows manipulation of environment variables. Using small snippets of text-matching code known as *regular expressions*, you can conditionally change the content of environment variables. The order in which SetEnvIf directives appear in the configuration files is important. Each SetEnvIf directive can reset an earlier SetEnvIf directive when used on the same environment variable. Be sure to keep that in mind when using the directives from this module.

**mod_speling**

*mod_speling* is used to enable correction of minor typos in URLs. If no file matches the requested URL, this module builds a list of the files in the requested directory and extracts those files that are the closest matches. It tries to correct only one spelling mistake.

**mod_status**

You can use *mod_status* to create a web page containing a plethora of information about a running Apache server. The page contains information about the internal status as well as statistics about the running Apache processes. This can be a great aid when you're trying to configure your server for maximum performance. It's also a good indicator of when something's amiss with your Apache server.

**mod_ssl**

*mod_ssl* provides Secure Sockets Layer (Versions 2 and 3) and transport layer security (Version 1) support for Apache. At least 30 directives exist that deal with options for encryption and client authorization and that can be used with this module.

**mod_unique_id**

*mod_unique_id* generates a unique request identifier for every incoming request. This ID is put into the UNIQUE_ID environment variable.

**mod_userdir**

The *mod_userdir* module enables mapping of a subdirectory in each user's home directory into your web tree. The module provides several ways to accomplish this.

**mod_usertrack**

*mod_usertrack* is used to generate a cookie for each user session. This can be used to track the user's click stream within your web tree. You must enable a custom log that logs this cookie into a log file.

**mod_vhost_alias**

*mod_vhost_alias* supports dynamically configured mass virtual hosting, which is useful for Internet service providers (ISPs) with many virtual hosts. However, for the average user, Apache's ordinary virtual hosting support should be more than sufficient.
There are two ways to host virtual hosts on an Apache server. You can have one IP address with multiple CNAMEs, or you can have multiple IP addresses with one name per address. Apache has different sets of directives to handle each of these options. (You learn more about virtual hosting in Apache in the next section of this chapter.)

Again, the available options and features for Apache modules are too numerous to describe completely in this chapter. You can find complete information about the Apache modules in the online documentation for the server included with Ubuntu or at the Apache Group’s website.

**Virtual Hosting**

One of the more popular services to provide with a web server is to host a virtual domain. Also known as a virtual host, a virtual domain is a complete website with its own domain name, as if it was a standalone machine, but it’s hosted on the same machine as other websites. Apache implements this capability in a simple way with directives in the `apache2.conf` configuration file.

Apache now can dynamically host virtual servers by using the `mod_vhost_alias` module you read about in the preceding section of the chapter. The module is primarily intended for ISPs and similar large sites that host a large number of virtual sites. This module is for more advanced users and, as such, it is outside the scope of this introductory chapter. Instead, this section concentrates on the traditional ways of hosting virtual servers.

**Address-Based Virtual Hosts**

After you’ve configured your Linux machine with multiple IP addresses, setting up Apache to serve them as different websites is simple. You need only put a `VirtualHost` directive in your `apache2.conf` file for each of the addresses you want to make an independent website:

```
<VirtualHost 212.85.67.67>
  ServerName gnulix.org
  DocumentRoot /home/virtual/gnulix/public_html
  TransferLog /home/virtual/gnulix/logs/access_log
  ErrorLog /home/virtual/gnulix/logs/error_log
</VirtualHost>
```

Use the IP address, rather than the hostname, in the `VirtualHost` tag.

You can specify any configuration directives within the `<VirtualHost>` tags. For example, you might want to set `AllowOverride` directives differently for virtual hosts than you do for your main server. Any directives that aren’t specified default to the settings for the main server.
Name-Based Virtual Hosts

Name-based virtual hosts enable you to run more than one host on the same IP address. You must add the names to your DNS as CNAMEs of the machine in question. When an HTTP client (web browser) requests a document from your server, it sends with the request a variable indicating the server name from which it's requesting the document. Based on this variable, the server determines from which of the virtual hosts it should serve content.

**NOTE**

Some older browsers are unable to see name-based virtual hosts because this is a feature of HTTP 1.1 and the older browsers are strictly HTTP 1.0–compliant. However, many other older browsers are partially HTTP 1.1–compliant, and this is one of the parts of HTTP 1.1 that most browsers have supported for a while.

Name-based virtual hosts require just one step more than IP address-based virtual hosts. You must first indicate which IP address has the multiple DNS names on it. This is done with the `NameVirtualHost` directive:

```
NameVirtualHost 212.85.67.67
```

You must then have a section for each name on that address, setting the configuration for that name. As with IP-based virtual hosts, you need to set only those configurations that must be different for the host. You must set the `ServerName` directive because it's the only thing that distinguishes one host from another:

```
<VirtualHost 212.85.67.67>
  ServerName bugserver.gnulix.org
  ServerAlias bugserver
  DocumentRoot /home/bugserver/htdocs
  ScriptAlias /home/bugserver/cgi-bin
  TransferLog /home/bugserver/logs/access_log
</VirtualHost>

<VirtualHost 212.85.67.67>
  ServerName pts.gnulix.org
  ServerAlias pts
  DocumentRoot /home/pts/htdocs
  ScriptAlias /home/pts/cgi-bin
  TransferLog /home/pts/logs/access_log
  ErrorLog /home/pts/logs/error_log
</VirtualHost>
```
TIP

If you are hosting websites on an intranet or internal network, users will likely use the shortened name of the machine rather than the FQDN. For example, users might type http://bugserver/index.html in their browser location field rather than http://bugserver.gnulix.org/index.html. In that case, Apache would not recognize that those two addresses should go to the same virtual host. You could get around this by setting up VirtualHost directives for both bugserver and bugserver.gnulix.org, but the easy way around it is to use the ServerAlias directive, which lists all valid aliases for the machine:

ServerAlias bugserver

For more information about VirtualHost, refer to the help system on http://localhost/_manual.

Logging

Apache provides logging for just about any web access information you might be interested in. Logging can help with:

- System resource management, by tracking usage
- Intrusion detection, by documenting bad HTTP requests
- Diagnostics, by recording errors in processing requests

Two standard log files are generated when you run your Apache server: access_log and error_log. They are found under the /var/log/apache2 directory. (Others include the SSL logs ssl_access_log, ssl_error_log and ssl_request_log.) All logs except for the error_log (by default, this is just the access_log) are generated in a format specified by the CustomLog and LogFormat directives. These directives appear in your apache2.conf file.

A new log format can be defined with the LogFormat directive:

```
LogFormat "%h %l %u %t "%r" %>s %b" common
```

The common log format is a good starting place for creating your own custom log formats. Note that most of the available log analysis tools assume you’re using the common log format or the combined log format—both of which are defined in the default configuration files.

The following variables are available for LogFormat statements:

- %a Remote IP address.
- %A Local IP address.
- %b Bytes sent, excluding HTTP headers. This is shown in Apache’s Combined Log Format (CLF). For a request without any data content, a - is shown instead of 0.
- %B Bytes sent, excluding HTTP headers.
- %{VARIABLE}e The contents of the environment variable VARIABLE.
- %f The filename of the output log.
- %h Remote host.
- %H Request protocol.
- %{HEADER}i The contents of HEADER; header line(s) in the request sent to the server.
- %l Remote log name (from identd, if supplied).
- %m Request method.
- %{NOTE}n The contents of note NOTE from another module.
- %{HEADER}o The contents of HEADER; header line(s) in the reply.
- %p The canonical port of the server serving the request.
- %P The process ID of the child that serviced the request.
- %q The contents of the query string, prepended with a ? character. If there's no query string, this evaluates to an empty string.
- %r The first line of request.
- %s Status. For requests that were internally redirected, this is the status of the original request—%>s for the last.
- %t The time, in common log time format.
- %{format}t The time, in the form given by format, which should be in strftime(3) format. See the section “Basic SSI Directives” later in this chapter for a complete list of available formatting options.
- %T The seconds taken to serve the request.
- %u Remote user from auth; this might be bogus if the return status (%s) is 401.
- %U The URL path requested.
- %v The server name according to the UseCanonicalName directive.
- %v The canonical ServerName of the server serving the request.

You can put a conditional in front of each variable to determine whether the variable is displayed. If the variable isn’t displayed, - is displayed instead. These conditionals are in the form of a list of numerical return values. For example, %!401u displays the value of REMOTE_USER unless the return code is 401.
You can then specify the location and format of a log file using the `CustomLog` directive:

```
CustomLog logs/access_log common
```

If it is not specified as an absolute path, the location of the log file is assumed to be relative to the `ServerRoot`.

**Other Web Servers for Use with Ubuntu**

To determine the best web server for your use, consider the needs of the website you manage. Does it need heavy security (for e-commerce), multimedia (music, video, and pictures), or the capability to download files easily? How much are you willing to spend for the software? Do you need software that is easy to maintain and troubleshoot or that includes tech support? The answers to these questions might steer you to something other than Apache.

The following sections list some of the more popular alternatives to using Apache as your web server.

**Sun ONE Web Server**

There is evidence that the Sun Java System Web Server (formerly known as the iPlanet Web Server, and subsequently Sun ONE Web Server) might be even more popular than Apache in strictly corporate arenas. The server got its start as the Netscape Enterprise Server—one of the first powerful web servers ever to hit the market. Sun ONE Web Server comes in many flavors, and all of them are big. In addition to the enterprise-level web server that can be run on Ubuntu, the software features application, messaging, calendar, and directory servers—just to name a few.

Sun ONE Web Server is great for handling big web needs, and it comes with an appropriately big price tag. It’s definitely not something to run the school website—unless your school happens to be a major state university with several regional campuses. For more information on Sun Java System Web Server, you can visit its website (wwws.sun.com/software/products/web_srvr/home_web_srvr.html). Since Oracle bought Sun, the future of this project is unknown, however at the time of this writing the website is still up and the product is still being sold.

**Nginx**

Pronounced “engine-x”, this is a lightweight and extremely fast web server. It is free and open source and is known for stability, high performance, and low resource use. It powers many well-known websites like Wordpress, Hulu, and SourceForge. It is not as configurable as Apache, nor as well documented in English since it originates from Russia, but for specific use cases it is an excellent option and is quite easy to set up and use. Take a closer look at http://nginx.org/en/ and http://wiki.nginx.org/Main.
Zope
Zope is another open-source web server making strong inroads in the web server market. What makes Zope different is that it is managed completely through a web-based graphic interface. This has broad appeal for those who are not enthused about a command-line-only interface.

Zope is a product of the Zope Corporation (formerly Digital Creations), the same firm that made the Python programming language. And, like all things open source, it is free. Information on Zope can be found at both www.zope.com (for the commercial version) and www.zope.org (for the open-source version).

lighttpd
Another speedy open-source lightweight server is lighttpd, or “lighty.” Like Nginx, lighttpd is designed for high-performance and low resource use. YouTube, Wikipedia and others are using lighttpd for its scalability and quickness. It is worth checking out at www.lighttpd.net.

- [http://news.netcraft.com/archives/web_server_survey.html](http://news.netcraft.com/archives/web_server_survey.html)—A statistical graph of web server usage by millions of servers. The research points out that Apache is by far the most widely used server for Internet sites.
This page intentionally left blank
File Transfer Protocol (FTP) was once considered the primary method used to transfer files over a network from computer to computer. FTP is still heavily used today, although many graphical FTP clients now supplement the original text-based interface command. As computers have evolved, so has FTP, and Ubuntu includes many ways with which to use a graphical interface to transfer files over FTP.

This chapter contains an overview of the available FTP software included with Ubuntu, along with some details concerning initial setup, configuration, and use of FTP-specific clients. Ubuntu also includes an FTP server software package named vsftpd, the Very Secure FTP Daemon, and a number of associated programs you can use to serve and transfer files with the FTP protocol.

Choosing an FTP Server

FTP uses a client/server model. As a client, FTP accesses a server, and as a server, FTP provides access to files or storage. Just about every computer platform available has software written to enable a computer to act as an FTP server, but Ubuntu provides the average user with the capability to do this without paying hefty licensing fees and without regard for client usage limitations.

There are two types of FTP servers and access: anonymous and standard. A **standard** FTP server requires an account name and password from anyone trying to access the server. **Anonymous** servers allow anyone to connect to the server to retrieve files. Anonymous servers provide the most flexibility, but they can also present a security risk.
Fortunately, as you will read in this chapter, Ubuntu is set up to use proper file and directory permissions and common-sense default configuration, such as disallowing root to perform an FTP login.

**NOTE**

Many Linux users now use OpenSSH and its suite of clients, such as the `sftp` command, for a more secure solution when transferring files. The OpenSSH suite provides the `sshd` daemon and enables encrypted remote logins (see Chapter 15, “Remote Access with SSH and Telnet,” for more information).

### Choosing an Authenticated or Anonymous Server

When you are preparing to set up your FTP server, you must first make the decision to install either the authenticated or anonymous service. **Authenticated** service requires the entry of a valid username and password for access. As previously mentioned, **anonymous** service allows the use of the username `anonymous` and an email address as a password for access.

Authenticated FTP servers are used to provide some measure of secure data transfer for remote users, but will require maintenance of user accounts as usernames and passwords are used. Anonymous FTP servers are used when user authentication is not needed or necessary, and can be helpful in providing an easily accessible platform for customer support or public distribution of documents, software, or other data.

If you use an anonymous FTP server in your home or business Linux system, it is vital that you properly install and configure it to retain a relatively secure environment. Generally, sites that host anonymous FTP servers place them outside the firewall on a dedicated machine. The dedicated machine contains only the FTP server and should not contain data that cannot be restored quickly. This dedicated-machine setup prevents malicious users who compromise the server from obtaining critical or sensitive data. For an additional, but by no means more secure setup, the FTP portion of the file system can be mounted read-only from a separate hard drive partition or volume, or mounted from read-only media, such as CD-ROM, DVD, or other optical storage.

### Ubuntu FTP Server Packages

The Very Secure `vsftpd` server is licensed under the GNU GPL. The server can be used for personal or business purposes and is the FTP server covered in the remainder of this chapter.

### Other FTP Servers

One alternative server is NcFTPd, available from www.ncftp.com. This server provides its own optimized daemon. Additionally, NcFTPd has the capability to cache directory listings of the FTP server in memory, thereby increasing the speed at which users can obtain a list of available files and directories. Although NcFTPd has many advantages over some other FTP servers, NcFTPd is not GPL-licensed software, and its licensing fees vary according to the maximum number of simultaneous server connections ($199 for 51 or more concurrent users and $129 for up to 50 concurrent users, but free to education institutions with a compliant domain name).
Installing FTP Software

As part of the standard installation, the client software for FTP is already installed. You can verify that some FTP-related software is installed on your system by using `dpkg`, `grep`, and `sort` commands in this query:

```
matthew@seymour:$ dpkg -get-selections | grep ftp | sort
ftp install
lftp install
```

Above is the output from a fresh installation of Ubuntu 10.10 and what you see are basic FTP clients. These allow you to use FTP to connect to other computers to interact with remote files. You need an FTP server to allow other systems to interact with files on your computer. In this chapter we will discuss one FTP server application, vsftpd.

NOTE

Do not confuse the ncftp client with ncftpd. The ncftp-3.1 package included with Ubuntu is the client software, a replacement for ftp-0.17, and includes the ncftpget and ncftpput commands for transferring files via the command line or by using a remote file uniform resource locator (URL) address. ncftpd is the FTP server, which can be downloaded from www.ncftpd.com.

Another FTP server package for Linux is ProFTPD, licensed under the GNU GPL. This server works well with most Linux distributions and has been used by a number of Linux sites, including ftp.kernel.org and ftp.sourceforge.net. ProFTPD is actively maintained and updated for bug fixes and security enhancements. Its developers recommend that you use the latest release (1.2.10 at the time of this writing) to avoid exposure to exploits and vulnerabilities. Browse to www.proftpd.org to download a copy.

Yet another FTP server package is Bsdftpd-ssl, which is based on the BSD ftpd (and distributed under the BSD license). Bsdftpd-ssl offers simultaneous standard and secure access using security extensions; secure access requires a special client. For more details, browse to http://bsdftpd-ssl.sc.ru.

Previously, this book covered an FTP server called wu-ftp. We had some concerns about it, such as the fact that when testing it to update this chapter we discover it runs as root by default and therefore presents a significant security risk. For that reason, and the fact that the package seems to be abandoned and no longer maintained by its authors, we are not covering it in this edition.

Finally, another alternative is to use Apache (and the HTTP protocol) for serving files. Using a web server to provide data downloads can reduce the need to monitor and maintain a separate software service (or directories) on your server. This approach to serving files also reduces system resource requirements and gives remote users a bit more flexibility when downloading (such as enabling them to download multiple files at once). See Chapter 17, “Apache Web Server Management,” for more information about using Apache.
If vsftpd is not installed, install the package vsftpd from the Ubuntu repositories. For more information about installing packages, see chapter 32, “Managing Software.”

NOTE
If you host an FTP server connected to the Internet, make it a habit to always install security updates and bug fixes for your server software.

The FTP User

Instead of files being uploaded or managed by a current user when anonymous connections are made to your FTP server, an FTP user is created when vsftp is installed. This user is not a normal user per se, but a name for anonymous FTP users. The FTP user entry in /etc/passwd looks like this:

The numbers will differ on each system because they depend on the number of configured users on the system, but the rest of the information will be the same.

NOTE
The FTP user, as discussed here, applies to anonymous FTP configurations and server setup. Our FTP user is configured to use /srv/ftp as the default directory. Other Linux distributions may use a different default directory, such as /usr/local/ftp, for FTP files and anonymous users.

This entry follows the standard /etc/passwd entry: username, password, User ID, Group ID, comment field, home directory, and shell. To learn more about /etc/password, see the section “Configuring Your Firewall” in Chapter 33, “Securing Your Machines.”

Each of the items in this entry is separated by colons. In the preceding example, you can see that the Ubuntu system hosting the server uses shadowed password because an x is present in the traditional password field. The shadow password system is important because it adds an additional level of security to Ubuntu; the shadow password system is normally installed during the Ubuntu installation.

The FTP server software uses this user account to assign permissions to users connecting to the server. By using a default shell of /bin/false for anonymous FTP users versus /bin/bash or some other standard, interactive shell, an anonymous FTP user, will be unable to log in as a regular user. /bin/false is not a shell, but a program usually assigned to an account that has been locked. As root inspection of the /etc/shadow file shows (see Listing 18.1), it is not possible to log in to this account, denoted by the * as the password.
LISTING 18.1 Shadow Password File ftp User Entry

```bash
# cat /etc/shadow
bin:*:11899:0:99999:7:::
daemon:*:11899:0:99999:7:::
adm:*:11899:0:99999:7:::
lp:*:11899:0:99999:7:::
...
ftp:*:12276:0:99999:7:::
... 
```

The shadow file (only a portion of which is shown in Listing 18.1) contains additional information not found in the standard /etc/passwd file, such as account expiration, password expiration, whether the account is locked, and the encrypted password. The * in the password field indicates that the account is not a standard login account; thus, it does not have a password.

Although shadow passwords are in use on the system, passwords are not transmitted in a secure manner when using FTP. Because FTP was written before the necessity of encryption and security, it does not provide the mechanics necessary to send encrypted passwords. Account information is sent in plain text on FTP servers; anyone with enough technical knowledge and a network sniffer can find the password for the account you connect to on the server. Many sites use an anonymous-only FTP server specifically to prevent normal account passwords from being transmitted over the Internet.

Figure 18.1 shows a portion of a Wireshark capture of an FTP session. The wireshark client is a graphical browser used to display network traffic in real time, and it can be used to watch packet data, such as an FTP login on a LAN.

**QUICK AND DIRTY FTP SERVICE**

Conscientious Linux administrators will take the time to carefully install, set up, and configure a production FTP server before offering public service or opening up for business on the Internet. However, you can set up a server very quickly on a secure LAN by following a few simple steps:

1. Ensure that the FTP server package is installed, networking is enabled, and firewall rules on the server allow FTP access. See Chapter 14, “Networking,” to learn about firewalling.

2. If anonymous access to server files is desired, create and populate the /srv/ftp/public directory. Do this by mounting or copying your content, such as directories and files, under this directory. You don’t want to use symlinks, however, because a clever anonymous user could easily use that against you to access other parts of your file system. If you are new to this, copy your content into the directory.

3. Edit and then save the appropriate configuration file (such as /etc.vsftpd.conf for vsftpd) to enable access.

4. You must then start or restart the FTP server like this: `sudo service vsftpd restart`.
You can use the service to start, stop, restart, and query the vsftpd server. You must have root permission to use the vsftpd script to control the server, but any user can query the server (to see if it is running and to see its process ID number) using the status keyword, like this:

```
matthew@seymour:~$ sudo service vsftpd status
```

You can also use a shorter version just for finding the status of the FTP daemon like this:

```
matthew@seymour:~$ status vsftpd
```

Administrator permissions are not required to use the status command, so we do not need to use sudo.

### Configuring the Very Secure FTP Server

The server offers simplicity, security, and speed. It has been used by a number of sites, such as ftp.debian.org, ftp.gnu.org, rpmfind.net, and ftp.gimp.org. Note that despite its name, the Very Secure FTP server does not enable use of encrypted usernames or passwords.

Its main configuration file is vsftpd.conf, which resides under the /etc directory. The server has a number of features and default policies, but these can be overridden by changing the installed configuration file.

By default, anonymous logins are disabled. Users are not allowed to download or upload files, create new directories, or delete or rename files. The configuration file installed by
Ubuntu allows local users (that is, users with a login and shell account) to log in and then access their home directory. This configuration presents potential security risks because usernames and passwords are passed without encryption over a network. The best policy is to deny your users access to the server from their user accounts. To change these and other settings, edit the well-commented config file at /etc/vsftp.conf. For example, to change these two settings, edit the following lines:

```
# Allow anonymous FTP? (Disabled by default)
anonymous_enable=NO
#
# Uncomment this to allow local users to log in.
local_enable=YES
```

If you want to allow anonymous use of your FTP server, change NO to YES in the first couplet. As you can see in the second couplet, in Ubuntu 10.10, the local user setting was changed by Ubuntu from the default setting that did not allow local users to log in. We suggest commenting the line back out by placing a # at the front if you are going to run an anonymous FTP server. The default settings here work great if you are only allowing one user FTP access on the back end of a web server, for example, which is becoming the more common use for FTP, at least until we can convince the world to move to using SSH. See the “Telnet vs. SSH” discussion in Chapter 15 and replace “Telnet” with “FTP” for an idea of why this would be a good move.

### Controlling Anonymous Access

Toggling anonymous access features for your FTP server is done by editing the `vsftpd.conf` file and changing related entries to YES or NO in the file. Settings to control how the server works for anonymous logins include the following:

- **anonymous_enable**—Disabled by default. Use a setting of YES, and then restart the server to turn on anonymous access.
- **anon_mkdir_write_enable**—Allows or disallows creating of new directories.
- **anon_other_write_enable**—Allows or disallows deleting or renaming of files and directories.
- **anon_upload_enable**—Controls whether anonymous users can upload files (also depends on the global `write_enable` setting). This is a potential security and liability hazard and should rarely be used; if enabled, consistently monitor any designated upload directory.
- **anon_world_readable_only**—Allows only anonymous users to download files with world-readable (444) permission.

After making any changes to your FTP server configuration file, make sure to restart the server; this forces `vsftpd` to reread its settings.
Other vsftpd Server Configuration Files

You can edit vsftpd.conf to enable, disable, and configure many features and settings of the vsftpd server, such as user access, filtering of bogus passwords, and access logging. Some features might require the creation and configuration of other files, such as the following:

- /etc/vsftpd.user_list—Used by the userlist_enable and userlist_deny options; the file contains a list of usernames to be denied access to the server.

- /etc/vsftpd.chroot_list—Used by the chroot_list_enable and chroot_local_user options, this file contains a list of users who are either allowed or denied access to a home directory. An alternate file can be specified by using the chroot_list_file option.

- /etc/vsftpd.banned_emails—A list of anonymous password entries used to deny access if the deny_email_enable setting is enabled. An alternative file can be specified by using the banned_email option.

- /var/log/vsftpd.log—Data transfer information is captured to this file if logging is enabled using the xferlog_enable setting.

TIP

Whenever editing the FTP server files, make a backup file first. Also, it is always a good idea to comment out (using a pound sign at the beginning of a line) what is changed instead of deleting or overwriting entries. Follow these comments with a brief description explaining why the change was made. This leaves a nice audit trail of what was done, by whom, when, and why. If you have any problems with the configuration, these comments and details can help you troubleshoot and return to valid entries if necessary. You can use the dpkg command or other Linux tools (such as mc) to extract a fresh copy of a configuration file from the software’s package archive. Be aware, however, that the extracted version will replace the current version and overwrite your configuration changes.

Default vsftpd Behaviors

The contents of a file named .message (if it exists in the current directory) are displayed when a user enters the directory. This feature is enabled in the configuration file. FTP users are not allowed to perform recursive directory listings, which helps reduce bandwidth.

Other default settings are that specific user login controls are not set, but you can configure the controls to deny access to one or more users.

The data transfer rate for anonymous client access is unlimited, but you can set a maximum rate (in bytes per second) by using the anon_max_rate setting in vsftpd.conf. This can be useful for throttling bandwidth use during periods of heavy access, but waiting until heavy use occurs to change the setting could cause problems because you would kill any current connections when you restart the FTP server daemon. If you anticipate heavy FTP usage, change this setting before it happens or during a scheduled maintenance cycle. Another default is that remote clients will be logged out after five minutes of...
idle activity or a stalled data transfer. You can set idle and stalled connection timeouts by uncommenting idle_session_timeout and setting the time in seconds before idle sessions are disconnected.

Other settings that might be important for managing your system’s resources (networking bandwidth or memory) when offering FTP access include:

- dirlist_enable—Toggles directory listings on or off.
- dirmessage_enable—Toggles display of a message when the user enters a directory. A related setting is ls_recurse_enable, which can be used to disallow recursive directory listings.
- download_enable—Toggles downloading on or off.
- max_clients—Sets a limit on the maximum number of connections.
- max_per_ip—Sets a limit on the number of connections from the same IP address.

### Using the ftphosts File to Allow or Deny FTP Server Connection

You can create a file in /etc called ftphosts to allow or deny specific users or addresses from connecting to the FTP server. The format of the file is the word allow or deny, optionally followed by a username, followed by an IP or a DNS address.

allow username address
deny username address

Listing 18.2 shows a sample configuration of this file.

**LISTING 18.2  ftphosts Configuration File for Allowing or Denying Users**

```
# Example host access file
#
# Everything after a '#' is treated as comment,
# empty lines are ignored
allow fatima 208.164.186.1 208.164.186.2 208.164.186.4
deny richard 208.164.186.5
allow jane ubuntuforums.org
deny john naughtysite.net
allow ahmed 192.168.101.*
allow ahmed *.ubuntu.com
allow ahmed *.matthewhelmke.net
deny anonymous 201.*
```

The * is a wildcard that matches any combination of that address. For example, allow ahmed *.matthewhelmke.net allows the user ahmed to log in to the FTP server from any
address that contains the domain name matthewhelmke.net. Similarly, the anonymous user is not allowed to access the FTP if the user is coming from a 201 public class C IP address. You should set the permissions on this file to 600.

Changes made to your system’s FTP server configuration files only become active after you restart inetd because configuration files are only parsed at startup. To restart inetd as root, issue the command `#/etc/init.d/inetutils-inetd restart`. This makes a call to the same shell script that is called at system startup and shutdown for any runlevel to start or stop the inet daemon. inetd should report its status as

```
# /etc/init.d/inetutils-inetd restart
Stopping internet superserver inetd: [ OK ]
Starting internet superserver inetd: [ OK ]
```

After it is restarted, the FTP server is accessible to all incoming requests.

Email is still the dominant form of communication over the Internet. It is fast, free, and easy to use. However, much of what goes on behind the scenes is extremely complicated and would appear scary to anyone who does not know much about how email is handled. Ubuntu comes equipped with a number of powerful applications that will help you build anything from a small email server, right through to large servers able to handle thousands of messages.

This chapter shows you how to configure Ubuntu to act as an email server. We look at the options available in Ubuntu and examine the pros and cons of each one. You will also learn how mail is handled in Linux, and to a lesser extent, UNIX.

How Email Is Sent and Received

Email is transmitted as plain text across networks around the world using the Simple Mail Transfer Protocol (SMTP). As the name implies, the protocol itself is fairly basic, and it has been extended to add further authentication and error reporting/messaging to satisfy the growing demands of modern email. Mail transfer agents, or MTAs, work in the background transferring email from server to server, allowing emails to be sent all over the world. You may have come across such MTA software such as Sendmail, Postfix, Fetchmail, Exim, or Qmail.

SMTP allows each computer that the email passes through to forward it in the right direction to the final destination. When you consider the millions of email servers across the world, you have to marvel at how simple it all seems.
Here is a simplified example of how email is successfully processed and sent to its destination:

1. matthew@seymourcray.net composes and sends an email message to heather@gracehopper.net.
2. The MTA at seymourcray.net receives Matthew’s email message and queues it for delivery behind any other messages that are also waiting to go out.
3. The MTA at seymourcray.net contacts the MTA at gracehopper.net on port 24. After gracehopper.net acknowledges the connection, the MTA at seymourcray.net sends the mail message. After gracehopper.net accepts and acknowledges receipt of the message, the connection is closed.
4. The MTA at gracehopper.net places the mail message into Heather’s incoming mailbox; Heather is notified that she has new mail the next time she logs on.

However, several things can go wrong during this process. Here are a few examples:

What if Heather does not exist at gracehopper.net? In this case, the MTA at gracehopper.net will reject the email and notify the MTA at seymourcray.net of what the problem is. The MTA at seymourcray.net will then generate an email message and send it to matthew@seymourcray.net, informing him that no Heather exists at gracehopper.net (or perhaps just silently discard the message and give the sender no indication of the problem, depending on how the email server is configured).

What happens if gracehopper.net doesn’t respond to seymourcray.net’s connection attempts? (Perhaps the server is down for maintenance.) The MTA at seymourcray.net notifies the sender that the initial delivery attempt has failed. Further attempts will be made at intervals decided by the server administrator until the deadline is reached, and the sender will be notified that the mail is undeliverable.

### The Mail Transport Agent

Several MTAs are available for Ubuntu, each with its pros and cons. Normally they are hidden under the skin of Ubuntu, silently moving mail between servers all over the world with need for little or no maintenance. Some MTAs are extremely powerful, being able to cope with hundreds of thousands of messages each day, whereas some are geared more toward smaller installations. Other MTAs are perhaps not as powerful, but are packed full with features. In the next section, we take a look at some of the more popular MTAs available for Ubuntu.

#### Sendmail

Sendmail handles the overwhelming majority of emails transmitted over the Internet today. It is extremely popular across the Linux/UNIX/BSD world and is well supported. A commercial version is available that has a GUI interface for ease of configuration.

As well as being popular, Sendmail is particularly powerful compared to some of the other MTAs. However, it is not without its downsides, and you will find that other MTAs can handle more email per second in a larger environment. The other issue with Sendmail is that it can be extremely complicated to set it up exactly as you want it. A few books are
available specifically for Sendmail, but the most popular one has more than a thousand pages, reflecting the complex nature of Sendmail configuration.

We can be thankful, however, that the default configuration for Sendmail works fine for most basic installations out of the box, making further configurations unnecessary. Even if you want to use it as a basic email server, you only need to do some minor tweaks. The level of complexity associated with Sendmail often leads to system administrators replacing it with one of the other alternatives that is easier to configure.

**Postfix**

Postfix has its origins as the IBM Secure Mailer, but was released to the community by IBM. Compared to Sendmail, it is much easier to administer and has a number of speed advantages. Postfix offers a pain-free replacement for Sendmail, and you are able to literally replace Sendmail with Postfix without the system breaking a sweat. In fact, the applications that rely on Sendmail will automatically use Postfix instead and carry on working correctly (because Postfix uses a Sendmail wrapper, which deceives other programs into thinking that Postfix is Sendmail). This wrapper, or more correctly interface, makes switching to Postfix extremely easy if you are already running Sendmail. Postfix also happens to be the MTA of choice for Ubuntu, so it is this one that we spend more time on later in this chapter.

For enhanced security, many Postfix processes used to use the `chroot` facility (which restricts access to only specific parts of the file system) for improved security, and there are no `setuid` components in Postfix. With the current release of Ubuntu, a `chroot` configuration is *no longer used* and is, in fact, discouraged by the Postfix author. You can manually reconfigure Postfix to a `chroot` configuration, but that is no longer supported by Ubuntu.

If you are starting from scratch, Postfix is considered a better choice than Sendmail.

**Qmail and Exim**

Qmail is a direct competitor to Postfix but is not provided with Ubuntu. Qmail is designed to be easier to use than Sendmail, as well as faster and more secure. However, Qmail isn’t a drop-in replacement for Sendmail, so migrating an existing Sendmail installation to Qmail is not quite as simple as migrating from Sendmail to Postfix. Qmail is relatively easy to administer, and it integrates with a number of software add-ons, including web mail systems and POP3 servers. Qmail is available from www.qmail.org/.

Exim is yet another MTA, and it is available at www.exim.org/. Exim is considered faster and more secure that Sendmail or Postfix, but is much different to configure that either of those. Exim and Qmail use the `maildir` format rather than `mbox`, so both are considered “NFS safe” (see the following sidebar).

---

**MDIR VERSUS MAILBOX**

Qmail also introduced `maildir`, which is an alternative to the standard UNIX method of storing incoming mail. `maildir` is a more versatile system of handling incoming email, but it requires your email clients to be reconfigured, and it is not compatible with the traditional UNIX way of storing incoming mail. You will need to use mail programs that recognize the `maildir` format. (The modern programs do.)
The traditional \texttt{mbox} format keeps all mail assigned to a folder concatenated as a single file and maintains an index of individual emails. With \texttt{maildir}, each mail folder has three subfolders: \texttt{/cur}, \texttt{/new}, and \texttt{/tmp}. Each email is kept in a separate, unique file. If you are running a mail server for a large number of people, you should select a file system that can efficiently handle a large number of small files.

\texttt{mbox} does offer one major disadvantage. While you are accessing the monolithic \texttt{mbox} file that contains all your email, suppose that some type of corruption occurs, either to the file itself or to the index. Recovery from this problem can prove difficult. The \texttt{mbox} files are especially prone to problems if the files are being accessed over a network and can result in file corruption; one should avoid accessing \texttt{mbox} mail mounted over NFS, the Network File System, because file corruption can occur.

Depending on how you access your mail, \texttt{maildir} does permit the simultaneous access of \texttt{maildir} files by multiple applications; \texttt{mbox} does not.

The choice of a \textit{mail user agent (MUA)}, or email client, also affects your choice of mail directory format. For example, the \texttt{pine} program does not cache any directory information and must reread the mail directory any time it accesses it. If you are using \texttt{pine}, \texttt{maildir} is a poor choice. More-advanced email clients perform caching, so \texttt{maildir} might be a good choice, although the email client cache can get out of synchronization. It seems that no perfect choice exists.

Ubuntu provides you with mail alternatives that have both strong and weak points. Be aware of the differences among the alternatives and frequently reevaluate your selection to make certain that it is the best one for your circumstances.

### Choosing an MTA

Other MTAs are available for use with Ubuntu, but those discussed in the previous sections are the most popular. Which one should you choose? That depends on what you need to do. Postfix’s main strengths is that it scales well and can handle large volumes of email at high speeds, not to mention that it is much easier to configure than the more cryptic Sendmail. However, you may find that there are specific things that you need that only Sendmail can provide. It is easy to switch between MTAs when you need to.

### The Mail Delivery Agent

SMTP is a server-to-server protocol that was designed to deliver mail to systems that are always connected to the Internet. Dial-up systems connect only at the user’s command; they connect for specific operations, and are frequently disconnected. To accommodate this difference, many mail systems also include a \textit{mail delivery agent}, or MDA. The MDA transfers mail to systems without permanent Internet connections. The MDA is similar to an MTA (see the following note), but does not handle deliveries between systems and does not provide an interface to the user.
The MDA uses the POP3 or IMAP protocols for this process. In a manner similar to a post office box at the post office, POP3 and IMAP implement a “store and forward” process that alleviates the need to maintain a local mail server if all you want to do is read your mail. For example, dial-up Internet users can intermittently connect to their ISP’s mail server to retrieve mail using Fetchmail—the MDA recommended by Ubuntu (see the section “Using Fetchmail to Retrieve Mail” later in this chapter).

The Mail User Agent

The mail user agent, or MUA, is another necessary part of the email system. The MUA is a mail client, or mail reader, that allows the user to read and compose email and provides the user interface. (It is the email application itself that most users are familiar with as “email.”) Some popular UNIX command-line MUAs are elm, pine, and mutt. Ubuntu also provides modern GUI MUAs: Evolution, Thunderbird, Mozilla Mail, Balsa, Sylpheed, and KMail. For comparison, common non-UNIX MUAs are Microsoft Outlook, Outlook Express, Pegasus Mail, and Apple Inc.’s Mail.

The Microsoft Windows and Macintosh MUAs often include some MTA functionality; UNIX does not. For example, Microsoft Outlook can connect to your Internet provider’s mail server to send messages. On the other hand, UNIX MUAs generally rely on an external MTA such as Sendmail. This might seem like a needlessly complicated way to do things, and it is if used to connect a single user to her ISP. For any other situation, however, using an external MTA allows you much greater flexibility because you can use any number of external programs to handle and process your email functions and customize the service. Having the process handled by different applications gives you great control over how you provide email service to users on your network, as well as to individual and small office/home office (SOHO) users.

For example, you could do the following:

- Use Evolution to read and compose mail.
- Use Sendmail to send your mail.
- Use xbiff to notify you when you have new mail.
- Use Fetchmail to retrieve your mail from a remote mail server.
- Use Procmail to automatically sort your incoming mail based on sender, subject, or many other variables.
- Use Spamassassin to eliminate the unwanted messages before you read them.
Basic Postfix Configuration and Operation

Because Postfix is the Ubuntu-recommended MTA, the following sections provide a brief explanation and examples for configuring and operating your email system. As mentioned earlier, however, Postfix is an extremely complex program with many configuration options. As such, this chapter only covers some of the basics.

Postfix is not installed by default. To use it, install the `postfix` package from the Ubuntu software repositories. During installation you will be asked a series of questions to help configure Postfix immediately. You should research the settings for your situation before you start; some are merely preferential, but others are based on your hardware, network, and use case. You will be asked:

**General type of mail configuration:** Internet Site

**System mail name:** mail.matthewhelmke.com

**Root and postmaster mail recipient:** <admin_user_name>

**Other destinations for mail:** mail.example.com, example.com, localhost.example.com, localhost

**Force synchronous updates on mail queue?** No

**Local networks:** 127.0.0.0/8

**Mailbox size limit (bytes):** 0

**Local address extension character:** +

**Internet protocols to use:** all

If you make a mistake and answer a configuration question incorrectly, you can go back through the process again by entering this from the command line:

```
matthew@seymour:~$ sudo dpkg-reconfigure postfix
```

Postfix configuration is maintained in files in the `/etc/postfix` directory with much of the configuration being handled by the file `main.cf`. You don't have to use the command above to change these settings, but may do so by editing the appropriate file(s). The syntax of the configuration file, `main.cf`, is fairly easy to read (see the following example):

```
# See /usr/share/postfix/main.cf.dist for a commented, more complete version
# Debian specific: Specifying a file name will cause the first
# line of that file to be used as the name. The Debian default
# is /etc/mailname.
myorigin = /etc/mailname

smtpd_banner = $myhostname ESMTP $mail_name (Ubuntu)
biff = no
# appending .domain is the MUA's job.

# downloading biff messages to maildir
mail_owner = mail_owner
```

# appending .domain is the MUA's job.
append_dot_mydomain = no

# Uncomment the next line to generate "delayed mail" warnings
#delay_warning_time = 4h

# TLS parameters
smtpd_tls_cert_file=/etc/ssl/certs/ssl-cert-snakeoil.pem
smtpd_tls_key_file=/etc/ssl/private/ssl-cert-snakeoil.key
smtpd_use_tls=yes
smtpd_tls_session_cache_database = btree:${queue_directory}/smtpd_scache
smtp_tls_session_cache_database = btree:${queue_directory}/smtp_scache

# See /usr/share/doc/postfix/TLS_README.gz in the postfix-doc package for
# information on enabling SSL in the smtp client.

myhostname = optimus
alias_maps = hash:/etc/aliases
alias_database = hash:/etc/aliases
mydestination = optimus, localhost.localdomain, , localhost
relayhost =
mynetworks = 127.0.0.0/8
mailbox_size_limit = 0
recipient_delimiter = +
inet_interfaces = all

A useful command for configuring Postfix is postconf. It allows you to display and change
many configuration settings without editing and saving configuration files. The
command’s syntax is rather complex, but once learned it becomes a faster way to quickly
adjust settings. For example, the following command sets the
myhostname parameter:

matthew@seymour:~$ sudo postconf -e
myhostname=mail.matthewhelmke.com

You can learn more about postconf from the man page.

You start, stop, and restart Postfix using this command, using the appropriate one of those
three action words:

matthew@seymour:~$ sudo /etc/init.d/postfix start

Complicated email server setup is beyond the scope of this book, and we would point you
in the direction of Postfix: The Definitive Guide, by Kyle Dent. This is a great reference, and
rather unusual because it is a complete and useful reference in only 250 pages or so.
However, if you want to know something specific about Postfix, this is the book to read.

However, the following five sections address some commonly used advanced options. For
more information on Postfix, as well as other MTAs, see the “Reference” section at the end
of this chapter.
Configuring Masquerading

Sometimes you might want to have Postfix masquerade as a host other than the actual hostname of your system. Such a situation could occur if you have a dial-up connection to the Internet and your ISP handles all your mail for you. In this case, you will want Postfix to masquerade as the domain name of your ISP. For example, the following will strip any messages that come from matthew.gracehopper.net to just gracehopper.net:

```
masquerade_domains = gracehopper.net
```

Using Smart Hosts

If you do not have a full-time connection to the Internet, you will probably want to have Postfix send your messages to your ISPs mail server and let it handle delivery for you. Without a full-time Internet connection, you could find it difficult to deliver messages to some locations (such as some underdeveloped areas of the world where email services are unreliable and sporadic). In those situations, you can configure Postfix to function as a smart host by passing email on to another sender instead of attempting to deliver the email directly. You can use a line such as the following in the main.cf file to enable a smart host:

```
relayhost = mail.isp.net
```

This line causes Postfix to pass any mail it receives to the server mail.isp.net rather than attempt to deliver it directly. Smart hosting will not work for you if your ISP, like many others, blocks any mail relaying. Some ISPs block relaying because it is frequently used to disseminate spam.

Setting Message Delivery Intervals

As mentioned earlier, Postfix typically attempts to deliver messages as soon as it receives them, and again at regular intervals after that. If you have only periodic connections to the Internet, as with a dial-up connection, you likely would prefer Sendmail to hold all messages in the queue and attempt to deliver them whenever you connect to your ISP.

As dialup connections have become the exception rather than the rule and are now quite rare, Ubuntu does not configure them by default and does not include the pppd daemon in the default installation. If you need this, install pppd from the Ubuntu software repositories. You can then configure Postfix to hold messages for later delivery by adding the following line to /etc/ppp/peers/ppp0:

```
/usr/sbin/sendmail -q
```

This line causes Postifix to automatically send all mail when connecting to your ISP.
However, Postfix will still attempt to send mail regardless of whether the computer is on or off line, meaning that your computer may dial out just to send email. To disable this, you need to enter the following line into `mail.cf`:

```
defer_transports = smtp
```

This stops any unwanted telephone calls from being placed!

---

**TIP**

If you use networking over a modem, there is a configuration file for `pppd` called `ppp0`, which is located in `/etc/ppp/peers`. Any commands in this file automatically run each time the PPP daemon is started. You can add the line `sendmail -q` to this file to have your mail queue automatically processed each time you dial up your Internet connection.

---

**Mail Relaying**

By default, Postfix will not relay mail that did not originate from the local domain. This means that if a Postfix installation running at gracehopper.net receives mail intended for seymourcray.net, and that mail did not originate from gracehopper.net, the mail will be rejected and will not be relayed. If you want to allow selected domains to relay through you, add an entry for the domain to the `main.cf` file like this:

```
mynetworks = 192.168.2.0/24, 10.0.0.2/24, 127.0.0.0/8
```

The IP address needs to be specified in CIDR format. For a handy calculator, head on over to www.subnet-calculator.com/cidr.php. You must restart Postfix for this change to take effect.

---

**CAUTION**

You need a good reason to relay mail; otherwise, do not do it. Allowing all domains to relay through you will make you a magnet for spammers who will use your mail server to send spam. This can lead to your site being blacklisted by many other sites, which then will not accept any mail from you or your site’s users—even if the mail is legitimate!

---

**Forwarding Email with Aliases**

Aliases allow you to have an infinite number of valid recipient addresses on your system, without having to worry about creating accounts or other support files for each address. For example, most systems have “postmaster” defined as a valid recipient, but do not have an actual login account named “postmaster.” Aliases are configured in the file `/etc/aliases`. Here is an example of an alias entry:

```
postmaster: root
```
This entry forwards any mail received for “postmaster” to the root user. By default, almost all the aliases listed in the /etc/aliases file forward to root.

**CAUTION**

Reading email as root is a security hazard; a malicious email message can exploit an email client and cause it to execute arbitrary code as the user running the client. To avoid this danger, you can forward all of root’s mail to another account and read it from there. You can choose one of two ways for doing this.

You can add an entry to the /etc/aliases file that sends root’s mail to a different account. For example, root: foobar would forward all mail intended for root to the account foobar.

The other way is to create a file named .forward in root’s home directory that contains the address that the mail should forward to.

Anytime you make a change to the /etc/aliases file, you will need to rebuild the aliases database before that change will take effect. This is done with the following:

$ sudo newaliases

### Using Fetchmail to Retrieve Mail

SMTP is designed to work with systems that have a full-time connection to the Internet. What if you are on a dial-up account? What if you have another system store your email for you and then you log in to pick it up once in a while? (Most users who are not setting up servers will be in this situation.) In this case, you cannot easily receive email using SMTP, and you need to use a protocol, such as POP3 or IMAP, instead.

**NOTE**

Remember when we said that some mail clients can include some MTA functionality? Microsoft Outlook and Outlook Express can be configured to use SMTP and, if you use a dial-up connection, will offer to start the connection and then use SMTP to send your mail, so a type of MTA functionality is included in those mail clients.

Unfortunately, many MUAs do not know anything about POP3 or IMAP. To eliminate that problem, you can use a program called Fetchmail to contact mail servers using POP3 or IMAP, download mail off the servers, and then inject those messages into the local MTA just as if they had come from a standard SMTP server. The following sections explain how to install, configure, and use the Fetchmail program.
Installing Fetchmail

Similar to other packages, Fetchmail can be installed using either synaptic or apt-get. You can get the latest version of Fetchmail at www.catb.org/~esr/fetchmail.

Configuring Fetchmail

After you have installed Fetchmail, you must create the file .fetchmailrc in your home directory, which provides the configuration for the Fetchmail program.

You can create and subsequently edit the .fetchmailrc file by using any text editor. The configuration file is straightforward and quite easy to create; the following sections explain the manual method for creating and editing the file. The information presented in the following sections does not discuss all the options available in the .fetchmailrc file, but covers the most common ones needed to get a basic Fetchmail installation up and running. You must use a text editor to create the file to include entries like the ones shown as examples—modified for your personal information, of course. For advanced configuration, see the man page for Fetchmail. The man page is well written and documents all the configuration options in detail.

CAUTION

The .fetchmailrc file is divided into three sections: global options, mail server options, and user options. It is important that these sections appear in the order listed. Do not add options to the wrong section. Putting options in the wrong place is one of the most common problems that new users make with Fetchmail configuration files.

Configuring Global Options

The first section of .fetchmailrc contains the global options. These options affect all the mail servers and user accounts that you list later in the configuration file. Some of these global options can be overridden with local configuration options, as you learn later in this section. Here is an example of the options that might appear in the global section of the .fetchmailrc file:

set daemon 600
set postmaster foobar
set logfile ./.fetchmail.log

The first line in this example tells Fetchmail that it should start in daemon mode and check the mail servers for new mail every 600 seconds, or 10 minutes. Daemon mode means that after Fetchmail starts, it will move itself into the background and continue running. Without this line, Fetchmail would check for mail once when it started and would then terminate and never check again.
The second option tells Fetchmail to use the local account foobar as a last-resort address. In other words, any email that it receives and cannot deliver to a specified account should be sent to foobar.

The third line tells Fetchmail to log its activity to the file ./fetchmail.log. Alternatively, you can use the line set syslog—in which case, Fetchmail will log through the syslog facility.

Configuring Mail Server Options
The second section of the .fetchmailrc file contains information on each of the mail servers that should be checked for new mail. Here is an example of what the mail section might look like:

poll mail.samplenet.org
proto pop3
no dns

The first line tells Fetchmail that it should check the mail server mail.samplenet.org at each poll interval that was set in the global options section (which was 600 seconds in our example). Alternatively, the first line can begin with skip. If a mail server line begins with skip, it will not be polled as the poll interval, but will only be polled when it is specifically specified on the Fetchmail command line.

The second line specifies the protocol that should be used when contacting the mail server. In this case, we are using the POP3 protocol. Other legal options are IMAP, APOP, and KPOP. You can also use AUTO here—in which case, Fetchmail will attempt to automatically determine the correct protocol to use with the mail server.

The third line tells Fetchmail that it should not attempt to do a Dynamic Name Server (DNS) lookup. You will probably want to include this option if you are running over a dial-up connection.

Configuring User Accounts
The third and final section of .fetchmailrc contains information about the user account on the server specified in the previous section. Here is an example:

user foobar
pass secretword
fetchall
no flush

The first line, of course, simply specifies the username that is used to log in to the email server, and the second line specifies the password for that user. Many security conscious people cringe at the thought of putting clear-text passwords in a configuration file, and they should if it is group or world readable. The only protection for this information is to make certain that the file is readable only by the owner; that is, with file permissions of 600.
The third line tells Fetchmail that it should fetch all messages from the server, even if they have already been read.

The fourth line tells Fetchmail that it should delete the messages from the mail server after it has completed downloading them. This is the default, so we would not really have to specify this option. If you want to delete the messages from the server after downloading them, use the option `flush`.

The configuration options you just inserted configured the entire `.fetchmailrc` file to look like this:

```plaintext
set daemon 600
set postmaster foobar
set logfile ./fetchmail.log

poll mail.samplenet.org
proto pop3
no dns

user foobar
pass secretword
fetchall
flush
```

This file tells Fetchmail to do the following:

- Check the POP3 server mail.samplenet.org for new mail every 600 seconds.
- Log in using the username foobar and the password secretword.
- Download all messages off the server.
- Delete the messages from the server after it has finished downloading them.
- Send any mail it receives that cannot be delivered to a local user to the account foobar.

As mentioned before, many more options can be included in the `.fetchmailrc` file than are listed here. However, these options will get you up and running with a basic configuration.

For additional flexibility, you can define multiple `.fetchmailrc` files to retrieve mail from different remote mail servers while using the same Linux user account. For example, you can define settings for your most often used account and save them in the default `.fetchmailrc` file. Mail can then quickly be retrieved like this:

```
$ fetchmail -a
1 message for matthew at mail.matthewhelmke.com (1108 octets).
reading message 1 of 1 (1108 octets) . flushed
```
By using Fetchmail's `-f` option, you can specify an alternative resource file and then easily retrieve mail from another server, as follows:

```
$ fetchmail -f .myothermailrc
2 messages for matthew at matthew.helmke.com (5407 octets).
reading message 1 of 2 (3440 octets) ... flushed
reading message 2 of 2 (1967 octets) . flushed
You have new mail in /var/spool/mail/matthew
```

By using the `-d` option, along with a time interval (in seconds), you can use Fetchmail in its daemon, or background mode. The command will launch as a background process and retrieve mail from a designated remote server at a specified interval. For more-advanced options, see the Fetchmail man page, which is well written and documents all options in detail.

**CAUTION**

Because the `.fetchmailrc` file contains your mail server password, it should be readable only by you. This means that it should be owned by you and should have permissions no greater than `600`. Fetchmail will complain and refuse to start if the `.fetchmailrc` file has permissions greater than this.

---

**Choosing a Mail Delivery Agent**

Because of the modular nature of mail handling, it is possible to use multiple applications to process mail and accomplish more than simply deliver it. Getting mail from the storage area and displaying it to the user is the purpose of the MDA. MDA functionality can be found in some of the mail clients (MUAs), which can cause some confusion to those still unfamiliar with the concept of UNIX mail. As an example, the Procmail MDA provides filtering based on rulesets; KMail and Evolution, both MUAs, provide filtering, but the MUAs pine, mutt, and Balsa do not. Some MDAs perform simple sorting, and other MDAs are designed to eliminate unwanted emails, such as spam and viruses.

You would choose an MDA based on what you want to do with your mail. We will look at five MDAs that offer functions you might find useful in your particular situation. If you have simple needs (just organizing mail by rules), one of the MUAs that offers filtering might be better for your needs. Ubuntu provides the Evolution MUA as the default selection (and it contains some MDA functionality as previously noted), so try that first and see whether it meets your needs. If not, investigate one of the following MDAs provided by Ubuntu.

Unless otherwise noted, all the MDA software is provided in the Ubuntu repositories. Chapter 32, “Managing Software,” details the general installation of any software.
**Procmail**

As a tool for advanced users, the Procmail application acts as a filter for email, as it is retrieved from a mail server. It uses rulesets (known as *recipes*) as it reads each email message. No default configuration is provided; you must manually create a `~/.procmail` file for each user, or users can create their own.

There is no systemwide default configuration file. The creation of the rulesets is not trivial and requires an understanding of the use of regular expressions that is beyond the scope of this chapter. Ubuntu does provide three examples of the files in `/usr/share/doc/procmail/examples`, as well as a fully commented example in the `/usr/share/doc/procmail` directory, which also contains a README and FAQ. Details for the rulesets can be found in the man page for Procmail as well as the man pages for `procmailrc`, `procmailsc`, and `procmaillex`, which contain examples of Procmail recipes.

**Spamassassin**

If you have used email for any length of time, you have likely been subjected to spam—unwanted email sent to thousands of people at the same time. Ubuntu provides an MDA named Spamassassin to assist you in reducing and eliminating unwanted emails. Easily integrated with Procmail and Sendmail, it can be configured for both system wide and individual use. It uses a combination of rule sets and blacklists (Internet domains known to mail spam).

Enabling Spamassassin is simple. You must first have installed and configured Procmail. The README file found in `/usr/share/doc/spamassassin` provides details on configuring the `procmail` file to process mail through Spamassassin. It will tag probable spam with a unique header; you can then have Procmail filter the mail in any manner you choose. One interesting use of Spamassasin is to use it to tag email received at special email accounts established solely for the purpose of attracting spam. This information is then shared with the Spamassassin site where these “spam trap” generated hits help the authors fine-tune the rulesets.

**Squirrelmail**

Perhaps you do not want to read your mail in an MUA. If you use your web browser often, it might make sense to read and send your mail via a web interface, such as the one used by Hotmail or Yahoo! Mail. Ubuntu provides Squirrelmail for just that purpose. Squirrelmail is written in PHP and supports IMAP and SMTP. It supports MIME attachments, as well as an address book and folders for segregating email.

You must configure your web server to work with PHP 4. Detailed installation instructions can be found in `/usr/share/doc/squirrelmail/INSTALL`. After it is configured, point your web browser to the default install location, `www.yourdomain.com/squirrelmail/`, to read and send email.
Virus Scanners

Although the currently held belief is that Linux is immune to email viruses targeted at Microsoft Outlook users, it certainly makes no sense for UNIX mail servers to permit infected email to be sent through them. Although Ubuntu does not provide a virus scanner by default, some of the more popular scanners are available in the Ubuntu repositories. Take a look at ClamAV as the most popular example.

Autoresponders

Autoresponders automatically generate replies to received messages; they are commonly used to notify others that the recipient is out of the office. Mercifully, Ubuntu does not include one by default, but you can find and install an autoresponder like vacation or gnarw1 from the Ubuntu software repositories. If you are subscribed to a mailing list, be aware that automatic responses from your account can be very annoying to others on the list. Please unsubscribe from mail lists before you leave the office with your autoresponder activated.

Alternatives to Microsoft Exchange Server

One of the last areas in which a Microsoft product has yet to be usurped by open-source software is a replacement for Microsoft Exchange Server. Many businesses use Microsoft Outlook and Microsoft Exchange Server to access email, as well as to provide calendaring, notes, file sharing, and other collaborative functions. General industry complaints about Exchange Server center around scalability, administration (backup and restore in particular), and licensing fees.

A “drop-in” alternative needs to have compatibility with Microsoft Outlook because it’s intended to replace Exchange Server in an environment in which there are Microsoft desktops in existence using Outlook. A “work-alike” alternative provides similar features to Exchange Server, but does not offer compatibility with the Microsoft Outlook client itself; the latter is typical of many of the open-source alternatives.

Several “drop-in” alternatives exist, none of which are fully open source because some type of proprietary connector is needed to provide the services to Microsoft Outlook clients (or provide Exchange services to the Linux Evolution client). For Outlook compatibility, the key seems to be the realization of a full, open implementation of MAPI, the Microsoft Messaging Application Program Interface. That goal is going to be difficult to achieve because MAPI is a poorly documented Microsoft protocol. For Linux-only solutions, the missing ingredient for many alternatives is a usable group calendaring/scheduling system similar in function to that provided by Exchange Server/Outlook.

Of course, independent applications for these functions abound in the open-source world, but one characteristic of “groupware” is its central administration; another is that all components can share information.
The following sections examine several of the available servers, beginning with Microsoft Exchange Server itself and moving toward those applications that have increasing incompatibility with it. None of these servers are provided with Ubuntu.

**Microsoft Exchange Server/Outlook Client**

Exchange Server and Outlook seem to be the industry benchmark because of their widespread deployment. They offer a proprietary server providing email, contacts, scheduling, public folders, task lists, journaling, and notes using Microsoft Outlook as the client and MAPI as the API. If you consider what Microsoft Exchange offers as the “full” set of features, no other replacement offers 100 percent of the features exactly as provided by Microsoft Exchange Server—even those considered “drop-in” replacements. The home page for the Microsoft Exchange server is www.microsoft.com/exchange/.

**CommuniGate Pro**

CommuniGate Pro is a proprietary, drop-in alternative to Microsoft Exchange Server, providing email, webmail, LDAP directories, a web server, file server, contacts, calendaring (third party), Voice over IP, and a list server. The CommuniGate Pro MAPI Connector provides access to the server from Microsoft Outlook and other MAPI-enabled clients. The home page for this server is www.stalker.com/.

**Oracle Beehive**

Oracle Beehive is probably the closest that you will get to an Exchange replacement, allowing you to collaborate by instant messaging, email, sharing files (workspaces), calendaring, and other tools. Beehive is available for Linux platforms and its homepage is www.oracle.com/us/products/middleware/beehive/index.html.

**Bynari**

Bynari provides a proprietary group of servers to act as a drop-in replacement for Microsoft Exchange Server for email, calendaring, public folders, scheduling, address book, webmail, and contacts. Although it runs on Linux, it offers no Linux clients although it can be used with Evolution and Thunderbird, and the connector provides services to Microsoft Outlook only. The home page is www.bynari.net/.

**Open-Xchange**

Open-Xchange has a great pedigree having been owned and developed by Novell/SUSE until being spun off by itself into its own company. Working with open standards, it provides a number of collaboration options and is firmly based on Linux. It can work with
a wide variety of protocols, making it one of the best connected suites available. You can get the open source version at www.open-xchange.com.

**phpgroupware**

phpgroupware is an open-source application written in PHP (and used with MySQL or postgresql plus a web server and an IMAP mail server). phpgroupware provides a web-based calendar, task list, address book, email, news headlines, and a file manager. Its modular nature enables you to plug in various components (around 50 at the last count) as you need them. The home page is www.phpgroupware.org/.

**PHProjekt**

PHProjekt is open-source software written in PHP (used with MySQL, postgresql, Oracle, Informix, or MS-sql). PHProjekt provides calendaring, contact manager, time card system, project management, online chat, threaded discussion forum, trouble ticket system, email, public files, notes bookmarks, voting system, task lists, reminders, site search, and integration with the PostNuke news site application. It provides no Exchange/Outlook compatibility whatsoever. The home page is www.PHProjekt.com/.

**Horde**

Horde is a PHP-based application framework. When combined with an HTTP server (Apache, Microsoft IIS, Netscape) and MySQL database, IMP/Horde offers modules that provide webmail, contact manager, calendar, CVS viewer, file manager, time tracking, email filter rules manager, notes, tasks, chat, newsgroups, forms, bug tracking, FAQ repository, and presentations. The home page is www.horde.org/.

You can never have enough of two things in this world: time and bandwidth. Ubuntu comes with a proxy server—Squid—that enables you to cache web traffic on your server so that websites load faster and users consume less bandwidth.

What Is a Proxy Server?

A proxy server lies between client machines—the desktops in your company—and the Internet. As clients request websites, they do not connect directly to the web and send the HTTP request. Instead, they connect to the local proxy server. The proxy then forwards their request on to the web, retrieves the result, and hands it back to the client. At its simplest, a proxy server really is just an extra layer between client and server, so why bother?

The three main reasons for deploying a proxy server are as follows:

- **Content control**—You want to stop people whiling away their work hours reading celebrity news or downloading MP3s.

- **Speed**—You want to cache common sites to make the most of your bandwidth.

- **Security**—You want to monitor what people are doing.

Squid is capable of all of these and more.
Installing Squid

Squid is easily installed the usual way from the Ubuntu software repositories where it is called squid. After Squid is installed, it is automatically enabled for each bootup. You can check this by running `ps aux | grep squid` when the machine boots. If for some reason you see nothing there, run `/etc/init.d/squid start`.

Configuring Clients

Before you configure your new Squid server, set up the local web browser to use it for its web access. Doing so enables you to test your rules as you are working with the configuration file.

To configure Firefox, select Preferences from the Edit menu. From the dialog that appears, select the Advanced settings using the icon in the top row, and within Advanced, select the Network tab. Then click the Settings button next to Configure how Firefox connects to the Internet and select the Manual Proxy Configuration option. Check the box beneath it labeled Use the Same Proxy for All Protocols. Enter 127.0.0.1 as the IP address and 3128 as the port number. See Figure 20.1 for how this should look. If you are configuring a remote client, specify the IP address of the Squid server rather than 127.0.0.1.

![Connection Settings](image)

FIGURE 20.1 Setting up Firefox to use 127.0.0.1 routes all its web requests through Squid.

Other web browsers such as Google Chrome, Opera, and so on can be configured similarly. The difference will be the labels used and menu locations for the options, so a little digging may be needed to discover where this may be adjusted in a specific browser’s settings.
Access Control Lists

The main Squid configuration file is `/etc/squid/squid.conf`, and the default Ubuntu configuration file is full of comments to help guide you. The default configuration file allows full access to the local machine but denies the rest of your network. This is a secure place to start; we recommend you try all the rules on yourself (`localhost`) before rolling them out to other machines.

Before you start, open two terminal windows. In the first, change to the directory `/var/log/squid` and run this command:

```bash
sudo tail -f access.log cache.log
```

That reads the last few lines from both files and (thanks to the `-f` flag) follows them so that any changes appear in there. This allows you to watch what Squid is doing as people access it. We refer to this window as the “log window,” so keep it open. In the other window (again, with sudo), bring up the file `/etc/squid/squid.conf` in your favorite editor. We refer to this window as the “config editor,” and you should keep it open, too.

To get started, search for the string `acl all`—this brings you to the access control section, which is where most of the work needs to be done. You can configure a lot elsewhere, but unless you have unusual requirements, you can leave the defaults in place.

### NOTE

The default port for Squid is 3128, but you can change that by editing the `http_port` line. Alternatively, you can have Squid listen on multiple ports by having multiple `http_port` lines: 80, 8000, and 8080 are all popular ports for proxy servers.

The `acl` lines make up your access control lists (ACLs). The first 16 or so define the minimum recommended configuration that set up ports to listen to, and so on. You can safely ignore these. If you scroll down further (past another short block of comments), you come to the `http_access` lines, which are combined with the `acl` lines to dictate who can do what. You can (and should) mix and match `acl` and `http_access` lines to keep your configuration file easy to read.

Just below the first block of `http_access` lines is a comment like `# INSERT YOUR OWN RULE(S) HERE TO ALLOW ACCESS FROM YOUR CLIENTS`. This is just what we are going to do. First, though, scroll just a few lines further; you should see these two lines:

```bash
http_access allow localhost
http_access deny all
```

They are self-explanatory: The first says, “Allow HTTP access to the local computer, but deny everyone else.” This is the default rule, as mentioned earlier. Leave that in place for now, and run `service squid start` to start the server with the default settings. If you have not yet configured the local web browser to use your Squid server, do so now so that you can test the default rules.
In your web browser (Firefox is assumed from here on, because it is the default in a standard Ubuntu install, but it makes little difference), go to the URL www.ubuntulinux.org. You should see it appear as normal in the browser, but in the log window you should see a lot of messages scroll by as Squid downloads the site for you and stores it in its cache. This is all allowed because the default configuration allows access to the localhost.

Go back to the config editor window and add this before the last two http_access lines:

http_access deny localhost

So, the last three lines should look like this:

http_access deny localhost
http_access allow localhost
http_access deny all

Save the file and quit your editor. Then, run this command:

```
kill -SIGHUP 'cat /var/run/squid.pid'
```

That looks for the process ID (PID) of the Squid daemon and then sends the SIGHUP signal to it, which forces it to reread its configuration file while running. You should see a string of messages in the log window as Squid rereads its configuration files. If you now go back to Firefox and enter a new URL, you should see the Squid error page informing you that you do not have access to the requested site.

The reason you are now blocked from the proxy is because Squid reads its ACL lines in sequence, from top to bottom. If it finds a line that conclusively allows or denies a request, it stops reading and takes the appropriate action. So, in the previous lines, localhost is being denied in the first line and then allowed in the second. When Squid sees localhost asking for a site, it reads the deny line first and immediately sends the error page—it does not even get to the allow line. Having a deny all line at the bottom is highly recommended so that only those you explicitly allow are able to use the proxy.

Go back to editing the configuration file and remove the deny localhost and allow localhost lines. This leaves only deny all, which blocks everyone (including the localhost) from accessing the proxy. Now we are going to add some conditional allow statements: We want to allow localhost only if it fits certain criteria.

Defining access criteria is done with the acl lines, so above the deny all line, add this:

```
acl newssites dstdomain news.bbc.co.uk slashdot.org
http_access allow newssites
```

The first line defines an access category called newssites, which contains a list of domains (dstdomain). The domains are news.bbc.co.uk and slashdot.org, so the full line reads, “Create a new access category called newssites that should filter on domain, and contain the two domains listed.” It does not say whether access should be granted or denied to that category; that comes in the next line. The line http_access allow newssites means,
“Allow access to the category newssites with no further restrictions.” It is not limited to localhost, which means that applies to every computer connecting to the proxy server.

Save the configuration file and rerun the `kill -SIGHUP` line from before to restart Squid; then go back to Firefox and try loading www.ubuntu.com. You should see the same error as before because that was not in our newssites category. Now try http://news.bbc.co.uk, and it should work. However, if you try www.slashdot.org, it will not work, and you might also have noticed that the images did not appear on the BBC News website either. The problem here is that specifying slashdot.org as the website is specific: It means that http://slashdot.org will work, whereas www.slashdot.org will not. The BBC News site stores its images on the site http://newsimg.bbc.co.uk, which is why they do not appear.

Go back to the configuration file, and edit the newssites ACL to this:

```
  acl newssites dstdomain .bbc.co.uk .slashdot.org
```

Putting the period in front of the domains (and in the BBC’s case, taking the news off, too) means that Squid will allow any subdomain of the site to work, which is usually what you will want. If you want even more vagueness, you can just specify *.com to match *.com addresses.

Moving on, you can also use time conditions for sites. For example, if you want to allow access to the news sites in the evenings, you can set up a time category using this line:

```
  acl freetime time MTWHFAS 18:00-23:59
```

This time, the category is called freetime and the condition is time, which means we need to specify what time the category should contain. The seven characters following that are the days of the week: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, and Sunday. Thursday and Saturday use capital H and A so they do not clash with Tuesday and Sunday.

With that category defined, you can change the `http_access` line to include it, like this:

```
  http_access allow newssites freetime
```

For Squid to allow access now, it must match both conditions—the request must be for either *.bbc.co.uk or slashdot.org, and during the time specified. If either condition does not match, the line is not matched and Squid continues looking for other matching rules beneath it. The times you specify here are inclusive on both sides, which means users in the freetime category will be able to surf from 18:00:00 until 23:59:59.

You can add as many rules as you like, although you should be careful to try to order them so that they make sense. Keep in mind that all conditions in a line must be matched for the line to be matched. Here is a more complex example:

- You want a category newssites that contains serious websites people need for their work.
You want a category playsites that contains websites people do not need for their work.

You want a category worktime that stretches from 09:00 to 18:00.

You want a category freetime that stretches from 18:00 to 20:00, when the office closes.

You want people to be able to access the news sites, but not the play sites, during working hours.

You want people to be able to access both the news sites and the play sites during the free time hours.

To do that, you need the following rules:

acl newssites dstdomain .bbc.co.uk .slashdot.org
acl playsites dstdomain .tomshardware.com ubuntu.org
acl worktime time MTWHF 9:00-18:00
acl freetime time MTWHF 18:00-20:00
http_access allow newssites worktime
http_access allow newssites freetime
http_access allow playsites freetime

NOTE

The letter D is equivalent to MTWHF in meaning, “All the days of the working week.”

Notice that there are two http_access lines for the newssites category: one for worktime and one for freetime. This is because all the conditions must be matched for a line to be matched. Alternatively, you can write this:

http_access allow newssites worktime freetime

However, if you do that and someone visits news.bbc.co.uk at 2:30 p.m. (14:30) on a Tuesday, Squid will work like this:

- Is the site in the newssites category? Yes, continue.
- Is the time within the worktime category? Yes, continue.
- Is the time within the freetime category? No; do not match rule, and continue searching for rules.

It is because of this that two lines are needed for the worktime category.

One particularly powerful way to filter requests is with the url_regex ACL line. This allows you to specify a regular expression that is checked against each request: If the expression matches the request, the condition matches.
For example, if you want to stop people downloading Windows executable files, you would use this line:

```
acl noexes url_regex -i exe$
```

The dollar sign means “end of URL,” which means it would match www.somesite.com/virus.exe but not www.executable.com/innocent.html. The -i part means “not case-sensitive,” so the rule will match .exe, .Exe, .EXE, and so on. You can use the caret sign (^) for “start of URL.”

For example, you could stop some pornography sites using this ACL:

```
acl noporn url_regex -i sex
```

Do not forget to run the kill -SIGHUP command each time you make changes to Squid; otherwise, it will not reread your changes. You can have Squid check your configuration files for errors by running `squid -k parse` as root. If you see no errors, it means your configuration is fine.

**NOTE**

It is critical that you run the command kill -SIGHUP and provide it the PID of your Squid daemon each time you change the configuration; without this, Squid will not reread its configuration files.

---

**Specifying Client IP Addresses**

The configuration options so far have been basic, and you can use many more to enhance the proxying system you want.

After you are past deciding which rules work for you locally, it is time to spread them out to other machines. You do so by specifying IP ranges that should be allowed or disallowed access, and you enter these into Squid using more ACL lines.

If you want to, you can specify all the IP addresses on your network, one per line. However, for networks of more than about 20 people or using Dynamic Host Control Protocol (DHCP), that is more work than necessary. A better solution is to use classless inter-domain routing (CIDR) notation, which allows you to specify addresses like this:

```
192.0.0.0/8
192.168.0.0/16
192.168.0.0/24
```

Each line has an IP address, followed by a slash and then a number. That last number defines the range of addresses you want covered and refers to the number of bits in an IP address. An IP address is a 32-bit number, but we are used to seeing it in dotted-quad notation: A.B.C.D. Each of those quads can be between 0 and 255 (although in practice some of these are reserved for special purposes), and each is stored as an 8-bit number.
The first line in the previous code covers IP addresses starting from 192.0.0.0; the /8 part means that the first 8 bits (the first quad, 192) is fixed and the rest is flexible. So, Squid treats that as addresses 192.0.0.0, 192.0.0.1, through to 192.0.0.255, then 192.0.1.0, 192.0.1.1, all the way through to 192.255.255.255.

The second line uses /16, which means Squid will allow IP addresses from 192.168.0.0 to 192.168.255.255. The last line has /24, which allows from 192.168.0.0 to 192.168.0.255.

These addresses are placed into Squid using the src ACL line, as follows:

```
acl internal_network src 10.0.0.0/24
```

That line creates a category of addresses from 10.0.0.0 to 10.0.0.255. You can combine multiple address groups together, like this:

```
acl internal_network src 10.0.0.0/24 10.0.3.0/24 10.0.5.0/24 192.168.0.1
```

That example allows 10.0.0.0 through 10.0.0.255, then 10.0.3.0 through 10.0.3.255, and finally the single address 192.168.0.1.

Keep in mind that if you are using the local machine and you have the web browser configured to use the proxy at 127.0.0.1, the client IP address will be 127.0.0.1, too. So, make sure you have rules in place for localhost.

As with other ACL lines, you need to enable them with appropriate `http_access allow` and `http_access deny` lines.

### Example Configurations

To help you fully understand how Squid access control works, and to give you a head start developing your own rules, the following are some ACL lines you can try. Each line is preceded with one or more comment lines (starting with a `#`) explaining what it does:

```
# include the domains news.bbc.co.uk and slashdot.org
# and not newsimg.bbc.co.uk or www.slashdot.org.
acl newssites dstdomain news.bbc.co.uk slashdot.org

# include any subdomains or bbc.co.uk or slashdot.org
acl newssites dstdomain .bbc.co.uk .slashdot.org

# only include sites located in Canada
acl canadasites dstdomain .ca

# only include working hours
acl workhours time MTWHF 9:00-18:00

# only include lunchtimes
acl lunchtimes time MTWHF 13:00-14:00
```
# only include weekends
acl weekends time AS 00:00-23:59

# include URLs ending in ".zip". Note: the \ is important,
# because "." has a special meaning otherwise
acl zipfiles url_regex -i \.zip$

# include URLs starting with https
acl httpsurls url_regex -i ^https

# include all URLs that match "hotmail"
url_regex hotmail url_regex -i hotmail

# include three specific IP addresses
acl directors src 10.0.0.14 10.0.0.28 10.0.0.31

# include all IPs from 192.168.0.0 to 192.168.0.255
acl internal src 192.168.0.0/24

# include all IPs from 192.168.0.0 to 192.168.0.255
# and all IPs from 10.0.0.0 to 10.255.255.255
acl internal src 192.168.0.0/24 10.0.0.0/8

When you have your ACL lines in place, you can put together appropriate http_access lines. For example, you might want to use a multilayered access system so that certain users (for example, company directors) have full access, whereas others are filtered. For example:

http_access allow directors
http_access deny hotmail
http_access deny zipfiles
http_access allow internal lunchtimes
http_access deny all

Because Squid matches those in order, directors will have full, unfiltered access to the web. If the client IP address is not in the directors list, the two deny lines are processed so that the user cannot download .zip files or read online mail at Hotmail. After blocking those two types of requests, the allow on line four allows internal users to access the web, as long as they do so only at lunchtime. The last line (which is highly recommended) blocks all other users from the proxy.

Reference

- www.squid-cache.org/—The home page of the Squid web proxy cache.
There are two excellent books on the topic of web caching. The first is *Squid: The Definitive Guide* (O'Reilly) by Duane Wessels, ISBN: 0-596-00162-2. The second is *Web Caching* (O'Reilly) also by Duane Wessels, ISBN: 1-56592-536-X.

Of the two, the former is more practical and covers the Squid server in depth. The latter is more theoretical, discussing how caching is implemented. Wessels is one of the leading developers on Squid, so both books are of impeccable technical accuracy.
CHAPTER 21
Administering Database Services

This chapter is an introduction to MySQL and PostgreSQL, two database systems that are available in the Ubuntu repositories. You will learn what these systems do, how the two programs compare, and how to consider their advantages and disadvantages. This information can help you choose and deploy which one to use for your organization’s database needs.

The database administrator (DBA) for an organization has several responsibilities, which vary according to the size and operations of the organization, supporting staff, and so on. Depending on the particular organization’s structure, if you are the organization’s DBA, your responsibilities might include the following:

- **Installing and maintaining database servers**—You might install and maintain the database software. Maintenance can involve installing patches as well as upgrading the software at the appropriate times. As DBA, you need to have root access to your system and know how to manage software (see Chapter 32, “Managing Software”). You also need to be aware of kernel, file system, and other security issues.

- **Installing and maintaining database clients**—The database client is the program used to access the database (you’ll learn more on that later in this chapter, in the section “Database Clients”), either locally or remotely over a network. Your responsibilities might include installing and maintaining these client programs on users’ systems. This chapter discusses
how to install and work with the clients from both the Linux command line and through its graphical interface database tools.

- **Managing accounts and users**—Account and user management include adding and deleting users from the database, assigning and administering passwords, and so on. In this chapter, you will learn how to grant and revoke user privileges and passwords for MySQL and PostgreSQL.

- **Ensuring database security**—To ensure database security, you need to be concerned with things like access control, which ensures that only authorized people can access the database, and permissions, which ensure that people who can access the database cannot do things they should not do. In this chapter, you will learn how to manage Secure Shell (SSH), web, and local GUI client access to the database. Planning and overseeing the regular backup of an organization’s database and restoring data from those backups is another critical component of securing the database.

- **Ensuring data integrity**—Of all the information stored on a server’s hard disk storage, chances are the information in the database is the most critical. Ensuring data integrity involves planning for multiple-user access and ensuring that changes are not lost or duplicated when more than one user is making changes to the database at the same time.

## A Brief Review of Database Basics

Database services under Linux that use the software discussed in this chapter are based on a client/server model. Database clients are often used to input data and to query or display query results from the server. You can use the command line or a graphical client to access a running server. Databases generally come in two forms: flat file and relational. A flat file database can be as simple as a text file with a space, tab, or some other character delimiting different parts of the information. One example of a simple flat file database is the `/etc/passwd` file. Another example could be a simple address book that might look something like this:

```
Doe~John~505 Some Street~Anytown~NY~12345~555-555-1212
```

You can use standard UNIX tools such as grep, awk, and perl to search for and extract information from this primitive database. Although this might work well for a small database such as an address book that only one person uses, flat file databases of this type have several limitations:

- **They do not scale well**—Flat file databases cannot perform random access on data. They can only perform sequential access. This means they have to scan each line in the file, one by one, to look for specific information. As the size of the database grows, access times increase and performance decreases.

- **Flat file databases are unsuitable for multi-user environments**—Depending on how the database is set up, it either enables only one user to access it at a time or...
allows two users to make changes simultaneously, and the changes could end up overwriting each other and cause data loss.

These limitations obviously make the flat file database unsuitable for any kind of serious work in even a small business—much less in an enterprise environment. Relational databases, or relational database management systems (RDBMSs) to give them their full name, are good at finding the relationships between individual pieces of data. An RDBMS stores data in tables with fields much like those in spreadsheets, making the data searchable, and sortable. RDBMSs are the focus of this chapter.

**NOSQL**

There is an exception to what was just said. A fairly new category of databases is now in use, usually referred to as “NoSQL” in casual conversation. Unlike typical flat file databases, NoSQL databases are a form of structured storage that is suitable for large and high traffic uses. These databases have been written and put into use in places where flat files are unsuitable but where relational databases are slower than desired. It is important to note that while NoSQL databases work great when scalability and speed are desirable, you can not be certain with all NoSQL databases that data is replicated and available instantly across a large installation. It generally is, but there is no guarantee of up-to-the-moment data. This is okay for some applications (web search), but would be disastrous for others (like a financial institution).

There are many forms of NoSQL databases each with different intents and applications. Some are created and used by big names you will recognize such as Google’s BigTable and Apache’s Cassandra. Ubuntu uses Apache’s CouchDB for several applications. Other common ones include MongoDB and BerkleyDB. For this chapter, we will concentrate on the more traditional relational databases that are used for most applications, but we urge you to keep an eye on what is happening in the NoSQL world.

Oracle, DB2, Microsoft SQL Server, and the freely available PostgreSQL and MySQL are all examples of RDBMSs. The following sections discuss how relational databases work and provide a closer look at some of the basic processes involved in administering and using databases. You will also learn about SQL, the standard language used to store, retrieve, and manipulate database data.

**How Relational Databases Work**

An RDBMS stores data in tables, which you can visualize as spreadsheets. Each column in the table is a field; for example, a column might contain a name or an address. Each row in the table is an individual record. The table itself has a name you use to refer to that table when you want to get data out of it or put data into it. Figure 21.1 shows an example of a simple relational database that stores name and address information.
In the example shown in Figure 21.1, the database contains only a single table. Most RDBMS setups are much more complex than this, with a single database containing multiple tables. Figure 21.2 shows an example of a database named `sample_database` that contains two tables.

**FIGURE 21.1** In this visualization of how an RDBMS stores data, the database stores four records (rows) that include name and address information, divided into seven fields (columns) of data.

In the example shown in Figure 21.1, the database contains only a single table. Most RDBMS setups are much more complex than this, with a single database containing multiple tables. Figure 21.2 shows an example of a database named `sample_database` that contains two tables.

**FIGURE 21.2** A single database can contain two tables—in this case, phonebook and `cd_collection`.

In the `sample_database` example, the phonebook table contains four records (rows) and each record hold three fields (columns) of data. The `cd_collection` table holds eight records, divided into five fields of data.

If you are thinking that there is no logical relationship between the phonebook table and the `cd_collection` table in the `sample_database` example, you are correct. In a relational database, users can store multiple tables of data in a single database—even if the data in one table is unrelated to the data in others.
For example, suppose you run a small company that sells widgets and you have a computerized database of customers. In addition to storing each customer's name, address, and phone number, you want to be able to look up outstanding order and invoice information for any of your customers. You could use three related tables in an RDBMS to store and organize customer data for just those purposes. Figure 21.3 shows an example of such a database.

In the example in Figure 21.3, we have added a customer ID field to each customer record. This field holds a customer ID number that is the unique piece of information that can be used to link all other information for each customer to track orders and invoices. Each customer is given an ID unique to him; two customers might have the same data in their name fields, but their ID field values will never be the same. The Customer ID field data in the Orders and Overdue tables replaces the Last Name, First Name, and Shipping Address field information from the Customers table. Now, when you want to run a search for any customer's order and invoice data, you can search based on one key rather than multiple keys. You get more accurate results in faster, easier-to-conduct data searches.

Now that you have an idea of how data is stored in an RDBMS and how the RDBMS structure enables you to work with that data, you are ready to learn how to input and output data from the database. This is where SQL comes in.
Understanding SQL Basics

SQL (pronounced “S-Q-L” or “sequel” depending on who is talking) is a database query language understood by virtually all RDBMSs available today. You use SQL statements to get data into and retrieve data from a database. As with statements in any language, SQL statements have a defined structure that determines their meanings and functions.

As a DBA, you should understand the basics of SQL, even if you will not be doing any of the actual programming yourself. Fortunately, SQL is similar to standard English, so learning the basics is simple.

Creating Tables

As mentioned previously, an RDBMS stores data in tables that look similar to spreadsheets. Of course, before you can store any data in a database, you need to create the necessary tables and columns to store the data. You do this by using the `CREATE` statement.

For example, the `cd_collection` table from Figure 21.2 has 5 columns, or fields: `id`, `title`, `artist`, `year`, and `rating`.

SQL provides several column types for data that define what kind of data will be stored in the column. Some of the available types are `INT`, `FLOAT`, `CHAR`, and `VARCHAR`. Both `CHAR` and `VARCHAR` hold text strings, with the difference being that `CHAR` holds a fixed-length string, whereas `VARCHAR` holds a variable-length string.

There are also special column types, such as `DATE`, that only take data in a date format, and `ENUMs` (enumerations), which can be used to specify that only certain values are allowed. If, for example, you wanted to record the genre of your CDs, you could use an `ENUM` column that accepts only the values `POP`, `ROCK`, `EASY_LISTENING`, and so on. You will learn more about `ENUM` later in this chapter.

Looking at the `cd_collection` table, you can see that three of the columns hold numerical data and the other two hold string data. In addition, the character strings are of variable length. Based on this information, you can discern that the best type to use for the text columns is type `VARCHAR`, and the best type to use for the others is `INT`. You should notice something else about the `cd_collection` table: One of the CDs is missing a rating, perhaps because we have not listened to it yet. This value, therefore, is optional; it starts empty and can be filled in later.

You are now ready to create a table. As mentioned before, you do this by using the `CREATE` statement, which uses the following syntax:

```
CREATE TABLE table_name (column_name column_type(parameters) options, ...);
```

You should know the following about the `CREATE` statement:

- **SQL commands are not case sensitive**—For example, `CREATE TABLE`, `create table`, and `Create Table` are all valid.
- **Whitespace is generally ignored**—This means you should use it to make your SQL commands clearer.
The following example shows how to create the table for the `cd_collection` database:

```sql
CREATE TABLE cd_collection
(
    id INT NOT NULL,
    title VARCHAR(50) NOT NULL,
    artist VARCHAR(50) NOT NULL,
    year VARCHAR(50) NOT NULL,
    rating VARCHAR(50) NULL
);
```

Notice that the statement terminates with a semicolon. This is how SQL knows you are finished with all the entries in the statement. In some cases, the semicolon can be omitted, and we will point out these cases when they arise.

**TIP**

SQL has a number of reserved keywords that cannot be used in table names or field names. For example, if you keep track of CDs you want to take with you on vacation, you would not be able to use the field name `select` because that is a reserved keyword. Instead, you should either choose a different name (e.g., `selected`) or just prefix the field name with an `f`, such as `fselect`.

**Inserting Data into Tables**

After you create the tables, you can put data into them. You can insert data manually with the `INSERT` statement, which uses the following syntax:

```sql
INSERT INTO table_name VALUES('value1', 'value2', 'value3', ...);
```

This statement inserts `value1`, `value2`, and so on into the table `table_name`. The values that are inserted constitute one row, or record, in the database. Unless specified otherwise, values are inserted in the order in which the columns are listed in the database table. If, for some reason, you want to insert values in a different order (or if you want to insert only a few values and they are not in sequential order), you can specify which columns you want the data to go in by using the following syntax:

```sql
INSERT INTO table_name (column1,column4) VALUES('value1', 'value2');
```

You can also fill multiple rows with a single `INSERT` statement, using syntax such as the following:

```sql
INSERT INTO table_name VALUES('value1', 'value2'),('value3', 'value4');
```

In this statement, `value1` and `value2` are inserted into the first row and `value3` and `value4` are inserted into the second row.
The following example shows how you would insert the Nevermind entry into the cd_collection table:

```
INSERT INTO cd_collection VALUES(9, 'Nevermind', 'Nirvana', '1991, 'NULL);
```

MySQL requires the NULL value for the last column (rating) if you do not want to include a rating. PostgreSQL, on the other hand, lets you get away with just omitting the last column. Of course, if you had columns in the middle that were null, you would need to explicitly state NULL in the INSERT statement.

Normally, INSERT statements are coded into a front-end program so users adding data to the database do not have to worry about the SQL statements involved.

**Retrieving Data from a Database**

Of course, the main reason for storing data in a database is so you can later look up, sort, and generate reports on that data. Basic data retrieval is done with the SELECT statement, which has the following syntax:

```
SELECT column1, column2, column3 FROM table_name WHERE search_criteria;
```

The first two parts of the statement—the SELECT and FROM parts—are required. The WHERE portion of the statement is optional. If it is omitted, all rows in the table table_name are returned.

The `column1, column2, column3` indicates the name of the columns you want to see. If you want to see all columns, you can also use the wildcard `*` to show all the columns that match the search criteria. For example, the following statement displays all columns from the cd_collection table:

```
SELECT * FROM cd_collection;
```

If you wanted to see only the titles of all the CDs in the table, you would use a statement such as the following:

```
SELECT title FROM cd_collection;
```

To select the title and year of a CD, you would use the following:

```
SELECT title, year FROM cd_collection;
```

If you wanted something a little fancier, you can use SQL to print the CD title followed by the year in parentheses, as is the convention. Both MySQL and PostgreSQL provide string concatenation functions to handle problems such as this. However, the syntax is different in the two systems.

Download from www.eBookTM.com
In MySQL, you can use the `CONCAT()` function to combine the title and year columns into one output column, along with parentheses. The following statement is an example:

```sql
SELECT CONCAT(title," (",year, ")") AS TitleYear FROM cd_collection;
```

That statement lists both the title and year under one column that has the label TitleYear. Note that there are two strings in the `CONCAT()` function along with the fields—these add whitespace and the parentheses.

In PostgreSQL, the string concatenation function is simply a double pipe (||). The following command is the PostgreSQL equivalent of the preceding MySQL command:

```sql
SELECT (genus||'' ('||species||')') AS TitleYear FROM cd_collection;
```

Note that the parentheses are optional, but they make the statement easier to read. Once again, the strings in the middle and at the end (note the space between the quotes) are used to insert spacing and parentheses between the title and year.

Of course, more often than not, you do not want a list of every single row in the database. Rather, you only want to find rows that match certain characteristics. For this, you add the WHERE statement to the SELECT statement. For example, suppose you want to find all the CDs in the `cd_collection` table that have a rating of 5. You would use a statement like the following:

```sql
SELECT * FROM cd_collection WHERE rating = 5;
```

Using the table from Figure 21.2, you can see that this query would return the rows for Trouser Jazz, Life for Rent, and The Two Towers. This is a simple query, and SQL is capable of handling queries much more complex than this. Complex queries can be written using logical AND and logical OR statements. For example, suppose you want to refine the query so it lists only those CDs that were not released in 2003. You would use a query like the following:

```sql
SELECT * FROM cd_collection WHERE rating = 5 AND year != 2003;
```

In SQL, != means “is not equal to.” So once again looking at the table from Figure 21.2, you can see that this query returns the rows for Trouser Jazz and The Two Towers but does not return the row for Life for Rent because it was released in 2003.

So, what if you want to list all the CDs that have a rating of 3 or 4 except those released in the year 2000? This time, you combine logical AND and logical OR statements:

```sql
SELECT * FROM cd_collection WHERE rating = 3 OR rating = 4 AND year != 2000;
```

This query would return entries for Mind Bomb, Natural Elements, and Combat Rock. However, it wouldn’t return entries for Adiemus 4 because it was released in 2000.
One of the most common errors among new database programmers is confusing logical AND and logical OR. For example, in everyday speech, you might say, “Find me all CDs released in 2003 and 2004.” At first glance, you might think that if you fed this statement to the database in SQL format, it would return the rows for *For All You’ve Done* and *Life for Rent*. In fact, it would return no rows at all. This is because the database interprets the statement as, “Find all rows in which the CD was released in 2003 and was released in 2004.” It is, of course, impossible for the same CD to be released twice without requiring a new ISBN and therefore a new database entry, so this statement would never return any rows, no matter how many CDs were stored in the table. The correct way to form this statement is with an OR statement instead of an AND statement.

SQL is capable of far more than is demonstrated here. But as mentioned before, this section is not intended to teach you all there is to know about SQL programming; rather, it teaches you the basics so you can be a more effective DBA.

**Choosing a Database: MySQL Versus PostgreSQL**

If you are just starting out and learning about using a database with Linux, the first logical step is to research which database will best serve your needs. Many database software packages are available for Linux; some are free, and others cost hundreds of thousands of dollars. Expensive commercial databases, such as Oracle, are beyond the scope of this book. Instead, this chapter focuses on two freely available databases: MySQL and PostgreSQL.

Both of these databases are quite capable, and either one could probably serve your needs. However, each database has a unique set of features and capabilities that might serve your needs better or make developing database applications easier for you.

We should note that Oracle recently bought Sun Microsystems, who owned MySQL. In the short term this may not have any impact, but the database world is watching to see what will happen with MySQL and there is are at least two groups who have forked the code to ensure that the database stays free and open source while still in active development. These groups have released and are working on Drizzle (http://drizzle.org) and MariaDB (http://kb.askmonty.org/v/MariaDB). Although no one really knows yet what will happen, we suggest keeping an eye on these projects and potential replacements for MySQL should the worst fears be realized and Oracle decides that the free MySQL is too much of a competitor to their paid database offerings and kills the project.

**Speed**

Until recently, the speed choice was simple: If the speed of performing queries was paramount to your application, you used MySQL. MySQL has a reputation for being an extremely fast database. Until recently, PostgreSQL was quite slow by comparison.
Newer versions of PostgreSQL have improved in terms of speed (when it comes to disk access, sorting, and so on). In certain situations, such as periods of heavy simultaneous access, PostgreSQL can be significantly faster than MySQL, as you will see in the next section. However, MySQL is still extremely fast when compared to many other databases.

**Data Locking**

To prevent data corruption, a database needs to put a lock on data while it is being accessed. As long as the lock is on, no other process can access the data until the first process has released the lock. This means that any other processes trying to access the data have to wait until the current process completes. The next process in line then locks the data until it is finished, and the remaining processes have to wait their turn, and so on.

Of course, operations on a database generally complete quickly, so in environments with a small number of users simultaneously accessing the database, the locks are usually of such short duration that they do not cause any significant delays. However, in environments in which many people are accessing the database simultaneously, locking can create performance problems as people wait their turn to access the database.

Older versions of MySQL lock data at the table level, which can be considered a bottleneck for updates during periods of heavy access. This means that when someone writes a row of data in the table, the entire table is locked so no one else can enter data. If your table has 500,000 rows (or records) in it, all 500,000 rows are locked any time one row is accessed. Once again, in environments with a relatively small number of simultaneous users, this doesn’t cause serious performance problems because most operations complete so quickly that the lock time is extremely short. However, in environments in which many people are accessing the data simultaneously, MySQL’s table-level locking can be a significant performance bottleneck.

PostgreSQL, on the other hand, locks data at the row level. In PostgreSQL, only the row currently being accessed is locked. The rest of the table can be accessed by other users. This row-level locking significantly reduces the performance impact of locking in environments that have a large number of simultaneous users. Therefore, as a general rule, PostgreSQL is better suited for high-load environments than MySQL.

The MySQL release bundled with Ubuntu gives you the choice of using tables with table-level or row-level locking. In MySQL terminology, MyISAM tables use table-level locking and InnoDB tables use row-level locking.

---

**NOTE**

MySQL’s data locking methods are discussed in more depth at www.mysql.com/doc/en/Internal_locking.html.

ACID Compliance in Transaction Processing to Protect Data Integrity

Another way MySQL and PostgreSQL differ is in the amount of protection they provide for keeping data from becoming corrupted. The acronym ACID is commonly used to describe several aspects of data protection:

- **Atomicity**—This means that several database operations are treated as an indivisible (atomic) unit, often called a *transaction*. In a transaction, either all unit operations are carried out or none of them are. In other words, if any operation in the atomic unit fails, the entire atomic unit is canceled.

- **Consistency**—Ensures that no transaction can cause the database to be left in an inconsistent state. Inconsistent states can be caused by database client crashes, network failures, and similar situations. Consistency ensures that, in such a situation, any transaction or partially completed transaction that would cause the database to be left in an inconsistent state is rolled back, or undone.

- **Isolation**—Ensures that multiple transactions operating on the same data are completely isolated from each other. This prevents data corruption if two users try to write to the same record at the same time. The way isolation is handled can generally be configured by the database programmer. One way that isolation can be handled is through locking, as discussed previously.

- **Durability**—Ensures that, after a transaction has been committed to the database, it cannot be lost in the event of a system crash, network failure, or other problem. This is usually accomplished through transaction logs. Durability means, for example, that if the server crashes, the database can examine the logs when it comes back up and it can commit any transactions that were not yet complete into the database.

PostgreSQL is ACID-compliant, but again MySQL gives you the choice of using ACID-compliant tables or not. MyISAM tables are not ACID-compliant, whereas InnoDB tables are. Note that ACID compliancy is no easy task: All the extra precautions incur a performance overhead.

**SQL Subqueries**

Subqueries allow you to combine several operations into one atomic unit, and they enable those operations to access each other’s data. By using SQL subqueries, you can perform some extremely complex operations on a database. In addition, using SQL subqueries eliminates the potential problem of data changing between two operations as a result of another user performing some operation on the same set of data. Both PostgreSQL and MySQL have support for subqueries in this release of Ubuntu, but this was not true in earlier releases.

**Procedural Languages and Triggers**

A *procedural language* is an external programming language that can be used to write functions and procedures. This allows you to do things that aren’t supported by simple SQL. A *trigger* allows you to define an event that will invoke the external function or procedure
you have written. For example, a trigger can be used to cause an exception if an `INSERT` statement containing an unexpected or out-of-range value for a column is given.

For example, in the CD tracking database, you could use a trigger to cause an exception if a user entered data that did not make sense. PostgreSQL has a procedural language called PL/pgSQL. Although MySQL has support for a limited number of built-in procedures and triggers, it does not have any procedural language. It does have a feature called stored procedures that is similar, but it doesn’t do quite the same thing.

### Configuring MySQL

A free and stable version of MySQL is included with Ubuntu. MySQL is also available from the website, www.mysql.com. The software is available in source code, binary, and APT format for Linux. You can use the Synaptic client to add the software to your system. See Chapter 7 for the details on adding (or removing) software.

After you have MySQL installed, you need to initialize the *grant tables* or permissions to access any or all databases and tables and column data within a database. You can do this by issuing `mysql_install_db` as root. This command initializes the grant tables and creates a MySQL root user.

**CAUTION**

The MySQL data directory needs to be owned by the user that owns the MySQL process, most likely `mysql` (you may need to change the directory’s owner using the `chown` command). In addition, only this user should have any permissions on this directory. (In other words, the permissions should be set to 700 by using `chmod`.) Setting up the data directory any other way creates a security hole.

Running `mysql_install_db` should generate output similar to the following:

```
matthew@seymour:~$ sudo mysql_install_db
Preparing db table
Preparing host table
Preparing user table
Preparing func table
Preparing tables_priv table
Preparing columns_priv table
Installing all prepared tables
020916 17:39:05 /usr/libexec/mysqld: Shutdown Complete
...
```

The command prepares MySQL for use on the system and reports helpful information. The next step is to set the password for the MySQL root user, which is discussed in the following section.
CAUTION
By default, the MySQL root user is created with no password. This is one of the first things you must change because the MySQL root user has access to all aspects of the database. The following section explains how to change the password of the user.

Setting a Password for the MySQL Root User
To set a password for the root MySQL user, you need to connect to the MySQL server as the root MySQL user; you can use the command `mysql -u root` to do so. This command connects you to the server with the MySQL client. When you have the MySQL command prompt, issue a command like the following to set a password for the root user:

```
mysql> SET PASSWORD FOR root = PASSWORD("secretword");
```

`secretword` should be replaced by whatever you want to be the password for the root user. You can use this same command with other usernames to set or change passwords for other database users.

After you enter a password, you can exit the MySQL client by typing `exit` at the command prompt.

Creating a Database in MySQL
In MySQL you create a database by using the `CREATE DATABASE` statement. To create a database, you connect to the server by typing `mysql -u root -p` and pressing Enter. After you do so, you are connected to the database as the MySQL root user and prompted for a password. After you enter the password, you are placed at the MySQL command prompt. Then you use the `CREATE DATABASE` command. For example, the following commands create a database called `animals`:

```
matthew@seymour:~$ mysql -u root -p
Enter password:
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 3.23.58

mysql>
CREATE DATABASE animals;
Query OK, 1 row affected (0.00 sec)
mysql>
```

Another way to create a database is to use the `mysqladmin` command, as the root user, with the create keyword and the name of a new database. For example, to create a new database named `reptiles`, you use a command line like this:

```
matthew@seymour:~# mysqladmin -u root -p create reptiles
```
Granting and Revoking Privileges in MySQL

You probably want to grant yourself some privileges, and eventually you will probably want to grant privileges to other users. Privileges, also known as *rights*, are granted and revoked on four levels:

- **Global-level**—These rights allow access to any database on a server.
- **Database-level**—These rights allow access to all tables in a database.
- **Table-level**—These rights allow access to all columns within a table in a database.
- **Column-level**—These rights allow access to a single column within a database’s table.

**NOTE**

Listing all the available privileges is beyond the scope of this chapter. See the MySQL documentation for more information.

To add a user account, you connect to the database by typing `mysql -u root -p` and pressing Enter. You are then connected as the root user and prompted for a password. (You did set a password for the root user, as instructed in the last section, right?) After you enter the root password, you are placed at the MySQL command prompt.

To grant privileges to a user, you use the `GRANT` statement, which has the following syntax:

```
grant what_to_grant ON where_to_grant TO user_name IDENTIFIED BY 'password';
```

The first option, `what_to_grant`, is the privileges you are granting to the user. These privileges are specified with keywords. For example, the `ALL` keyword is used to grant global-, database-, table-, and column-level rights for a specified user.

The second option, `where_to_grant`, specifies the resources on which the privileges should be granted. The third option, `user_name`, is the username to which you want to grant the privileges. Finally, the fourth option, `password`, is a password that should be assigned to this user. If this is an existing user who already has a password and you are modifying permissions, you can omit the `IDENTIFIED BY` portion of the statement.

For example, to grant all privileges on a database named `sampledata` to a user named `foobar`, you could use the following command:

```
GRANT ALL ON animals.* TO foobar IDENTIFIED BY 'secretword';
```

The user `foobar` can now connect to the database `sampledata` by using the password `secretword`, and `foobar` has all privileges on the database, including the ability to create
and destroy tables. For example, the user foobar can now log in to the server (by using the current hostname—shuttle2, in this example), and access the database like this:

```
matthew@seymour:~$ mysql -h shuttle2 -u foobar -p animals
Enter password:
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 43 to server version: 3.23.58
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
```

```
mysql>
```

**NOTE**

See the section “The MySQL Command-Line Client” for additional command-line options.

Later, if you need to revoke privileges from foobar, you can use the `REVOKE` statement. For example, the following statement revokes all privileges from the user foobar:

```
REVOKE ALL ON animals FROM foobar;
```

Advanced database administration, privileges, and security are very complex topics that are beyond the scope of this book. See the section “Reference” at the end of this chapter for links to online documentation. You can also check out Luke Welling’s and Laura Thompson’s book, *PHP and MySQL Development* from Sams Publishing.

## Configuring PostgreSQL

If you do not want to use the version of PostgreSQL bundled with Ubuntu, the latest PostgreSQL binary files and source are available at www.postgresql.org. The PostgreSQL packages are distributed as several files. At a minimum, you want the `postgresql` package. You should see the `README` file in the FTP directory `ftp://ftp.postgresql.org/pub/` to determine whether you need any other packages.

If you are installing from the Ubuntu package files, a necessary `postgres` user account (that is, an account with the name of the user running the server on your system) is created for you automatically:

```
matthew@seymour:~$ fgrep postgres /etc/passwd
postgres:x:26:26:PostgreSQL Server:/var/lib/postgresql:/bin/bash
```

Otherwise, you need to create a user called `postgres` during the installation. This user shouldn’t have login privileges because only root should be able to use `su` to become this user and no one will ever log in directly as the user. (See Chapter 10, “Managing Users,” for more information on how to add users to an Ubuntu system.) After you have added
the user, you can install each of the PostgreSQL packages you downloaded using the standard dpkg -i command for a default installation.

**Initializing the Data Directory in PostgreSQL**

Installation initializes the database and sets the permissions on the data directory to their correct values.

**CAUTION**

The initdb program sets the permissions on the data directory to 700. You should not change these permissions to anything else to avoid creating a security hole.

You can start the postmaster program with the following command (make sure you are still the user postgres):

```
matthew@seymour:~$ postmaster -D /usr/local/pgsql/data &
```

If you have decided to use a directory other than /usr/local/pgsql/data as the data directory, you should replace the directory in the postmaster command line with whatever directory you are using.

**TIP**

By default, Ubuntu makes the PostgreSQL data directory /var/lib/pgsql/data. This isn’t a very good place to store the data, however, because most people do not have the necessary space in the /var partition for any kind of serious data storage. Note that if you do change the data directory to something else (such as /usr/local/pgsql/data, as in the examples in this section), you need to edit the PostgreSQL startup file (named postgres) located in /etc/init.d to reflect the change.

**Creating a Database in PostgreSQL**

Creating a database in PostgreSQL is straightforward, but it must be performed by a user who has permissions to create databases in PostgreSQL—for example, initially the user named postgres. You can then simply issue the following command from the shell prompt (not the PSQL client prompt, but a normal shell prompt):

```
matthew@seymour:~# su - postgres
-bash-2.05b$ createdb database
```

where database is the name of the database you want to create.
The createdb program is actually a wrapper that makes it easier to create databases without having to log in and use psql. However, you can also create databases from within psql with the CREATE DATABASE statement. Here’s an example:

CREATE DATABASE database;

You need to create at least one database before you can start the psql client program. You should create this database while you’re logged in as the user postgres. To log in as this user, you need to use su to become root and then use su to become the user postgres. To connect to the new database, you start the psql client program with the name of the new database as a command-line argument, like this:

matthew@seymour:~$ psql sampledata

If you don’t specify the name of a database when you invoke psql, the command attempts to connect to a database that has the same name as the user as which you invoke psql (that is, the default database).

**Creating Database Users in PostgreSQL**

To create a database user, you use su to become the user postgres from the Linux root account. You can then use the PostgreSQL createuser command to quickly create a user who is allowed to access databases or create new database users, like this:

`matthew@seymour:~$ createuser heather`

Shall the new user be allowed to create databases? (y/n) y
Shall the new user be allowed to create more new users? (y/n) y
CREATE USER

In this example, the new user named phudson is created and allowed to create new databases and database users (you should carefully consider who is allowed to create new databases or additional users).

You can also use the PostgreSQL command-line client to create a new user by typing psql along with name of the database and then use the CREATE USER command to create a new user. Here is an example:

`CREATE USER foobar ;`

---

**CAUTION**

PostgreSQL allows you to omit the WITH PASSWORD portion of the statement. However, doing so causes the user to be created with no password. This is a security hole, so you should always use the WITH PASSWORD option when creating users.

---

**NOTE**

When you are finished working in the psql command-line client, you can type `\q` to get out of it and return to the shell prompt.
Deleting Database Users in PostgreSQL

To delete a database user, you use the `dropuser` command, along with the user's name, and the user's access is removed from the default database, like this:

```bash
matthew@seymour:~$ dropuser msmith
DROP USER
```

You can also log in to your database by using `psql` and then use the DROP USER commands. Here's an example:

```bash
matthew@seymour:~$ psql demodb
Welcome to psql, the PostgreSQL interactive terminal.
Type: \copyright for distribution terms
\h for help with SQL commands
\? for help on internal slash commands
\g or terminate with semicolon to execute query
\q to quit

demodb=# DROP USER msmith ;
DROP USER
demodb=# \q
```

Granting and Revoking Privileges in PostgreSQL

As in MySQL, granting and revoking privileges in PostgreSQL is done with the `GRANT` and `REVOKE` statements. The syntax is the same as in MySQL except that PostgreSQL doesn’t use the `IDENTIFIED BY` portion of the statement because with PostgreSQL, passwords are assigned when you create the user with the `CREATE USER` statement, as discussed previously. Here is the syntax of the `GRANT` statement:

```
GRANT what_to_grant ON where_to_grant TO user_name;
```

The following command, for example, grants all privileges to the user `foobar` on the database `sampledata`:

```
GRANT ALL ON sampledata TO foobar;
```

To revoke privileges, you use the `REVOKE` statement. Here is an example:

```
REVOKE ALL ON sampledata FROM foobar;
```

This command removes all privileges from the user `foobar` on the database `sampledata`.

Advanced administration and user configuration are complex topics. This section cannot begin to cover all the aspects of PostgreSQL administration or of privileges and users. For more information on administering PostgreSQL, see the PostgreSQL documentation or consult a book on PostgreSQL, such as *PostgreSQL* (Sams Publishing).
Database Clients

Both MySQL and PostgreSQL use a client/server system for accessing databases. In the simplest terms, the database server handles the requests that come into the database and the database client handles getting the requests to the server as well as getting the output from the server to the user.

Users never interact directly with the database server even if it happens to be located on the same machine they are using. All requests to the database server are handled by a database client, which might or might not be running on the same machine as the database server.

Both MySQL and PostgreSQL have command-line clients. A command-line client is a very primitive way of interfacing with a database and generally isn’t used by end users. As a DBA, however, you use the command-line client to test new queries interactively without having to write front-end programs for that purpose. In later sections of this chapter, you will learn a bit about the MySQL graphical client and the web-based database administration interfaces available for both MySQL and PostgreSQL.

The following sections examine two common methods of accessing a remote database, a method of local access to a database server, and the concept of web access to a database.

NOTE

You should consider access and permission issues when setting up a database. Should users be able to create and destroy databases? Or should they only be able to use existing databases? Will users be able to add records to the database and modify existing records? Or should users be limited to read-only access to the database? And what about the rest of the world? Will the general public need to have any kind of access to your database through the Internet? As DBA, you must determine the answers to these questions.

SSH Access to a Database

Two types of remote database access scenarios are briefly discussed in this section. In the first scenario, the user directly logs in to the database server through SSH (to take advantage of the security benefits of encrypted sessions) and then starts a program on the server to access the database. In this case, shown in Figure 21.4, the database client is running on the database server itself.

In the other scenario, shown in Figure 21.5, the user logs in to a remote host through SSH and starts a program on it to access the database, but the database is actually running on a different system. Three systems are now involved—the user's workstation, the remote host running the database client, and the remote host running the database server.
The user logs in to the database server located on host **simba** from the workstation (host **cheetah**). The database client is running on **simba**.

The important thing to note in Figure 21.5 is the middleman system **leopard**. Although the client is no longer running on the database server itself, it isn’t running on the user’s local workstation, either.
Local GUI Client Access to a Database

A user can log in to the database server by using a graphical client (which could be running on Windows, Macintosh, or a UNIX workstation). The graphical client then connects to the database server. In this case, the client is running on the user's workstation. Figure 21.6 shows an example.

![Diagram of database server and graphical client](image)

**FIGURE 21.6** The user starts a GUI database program on the user's workstation (hostname cheetah). This program, which is the database client, then connects to the database server running on the host simba.

Web Access to a Database

In this section, we look at two basic examples of web access to the database server. In the first example, a user accesses the database through a form located on the World Wide Web. At first glance, it might appear that the client is running on the user's workstation. Of course, in reality it is not; the client is actually running on the web server. The web browser on the user's workstation simply provides a way for each user to enter the data that the user wants to send to the database and a way for the results sent from the database to be displayed to the user. The software that actually handles sending the request to the database is running on the web server in the form of a CGI script; a Java servlet; or embedded scripting such as the PHP or Sun Microsystems, Inc.'s JavaServer Pages (JSP).

Often, the terms *client* and *front end* are used interchangeably when speaking of database structures. However, Figure 21.7 shows an example of a form of access in which the client and the front end aren't the same thing at all. In this example, the front end is the form displayed in the user's web browser. In such cases, the client is referred to as *middleware*.

In another possible web access scenario, it could be said that the client is a two-piece application in which part of it is running on the user's workstation and the other part is running on the web server. For example, the database programmer can use JavaScript in the web form to ensure that the user has entered a valid query. In this case, the user's query is partially processed on the user's own workstation and partially on the web server. Error checking is done on the user's own workstation, which helps reduce the load on the server and also helps reduce network traffic because the query is checked for errors before being sent across the network to the server.
The user accesses the database through the World Wide Web. The front end is the user’s web browser, the client is running on *leopard*, and the server is running on *simba*.

**The MySQL Command-Line Client**

The MySQL command-line client is *mysql*, and it has the following syntax:

```
mysql [options] [database]
```

Some of the available options for *mysql* are discussed in Table 21.1. *database* is optional, and if given, it should be the name of the database to which you want to connect.

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-h hostname</code></td>
<td>Connects to the remote host hostname (if the database server isn’t located on the local system).</td>
</tr>
<tr>
<td><code>-u username</code></td>
<td>Connects to the database as the user username.</td>
</tr>
<tr>
<td><code>-p</code></td>
<td>Prompts for a password. This option is required if the user you are connecting as needs a password to access the database. Note that this is a lowercase p.</td>
</tr>
<tr>
<td><code>-P n</code></td>
<td>Specifies n as the number of the port that the client should connect to. Note that this is an uppercase P.</td>
</tr>
<tr>
<td><code>-?</code></td>
<td>Displays a help message.</td>
</tr>
</tbody>
</table>

More options are available than are listed in Table 21.1, but these are the most common options. See the man page for *mysql* for more information on the available options.
Although mysql allows you to specify the password on the command line after the -p option, and thus allows you to avoid having to type the password at the prompt, you should never invoke the client this way. Doing so causes your password to display in the process list, and the process list can be accessed by any user on the system. This is a major security hole, so you should never give your password on the mysql command line.

You can access the MySQL server without specifying a database to use. After you log in, you use the help command to get a list of available commands, like this:

```
mysql> help
```

MySQL commands:

Note that all text commands must be first on line and end with ';

- `help (\h)` Display this help.
- `? (\?)` Synonym for 'help'.
- `clear (\c)` Clear command.
- `connect (\r)` Reconnect to the server. Optional arguments are db and host.
- `edit (\e)` Edit command with $EDITOR.
- `ego (\G)` Send command to mysql server, display result vertically.
- `exit (\q)` Exit mysql. Same as quit.
- `go (\g)` Send command to mysql server.
- `nopager (\n)` Disable pager, print to stdout.
- `notee (\t)` Don't write into outfile.
- `pager (\P)` Set PAGER [to_pager]. Print the query results via PAGER.
- `print (\p)` Print current command.
- `quit (\q)` Quit mysql.
- `rehash (\#)` Rebuild completion hash.
- `source (\.)` Execute a SQL script file. Takes a file name as an argument.
- `status (\s)` Get status information from the server.
- `tee (\T)` Set outfile [to_outfile]. Append everything into given outfile.
- `use (\u)` Use another database. Takes database name as argument.

You can then access a database by using the use command and the name of a database that has been created (such as animals) and that you are authorized to connect to, like this:

```
mysql> use animals
Database changed
```

```
mysql>
```
The PostgreSQL Command-Line Client

You invoke the PostgreSQL command-line client with the command `psql`. Like `mysql`, `psql` can be invoked with the name of the database to which you would like to connect. Also like `mysql`, `psql` can take several options. These options are listed in Table 21.2.

### Table 21.2 Command-Line Options to Use When Invoking `psql`

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-h hostname</code></td>
<td>Connects to the remote host <code>hostname</code> (if the database server isn’t located on the local system).</td>
</tr>
<tr>
<td><code>-p n</code></td>
<td>Specifies <code>n</code> as the number of the port that the client should connect to. Note that this is a lowercase <code>p</code>.</td>
</tr>
<tr>
<td><code>-U username</code></td>
<td>Connects to the database as the user <code>username</code>.</td>
</tr>
<tr>
<td><code>-W</code></td>
<td>Prompts for a password after connecting to the database. In PostgreSQL 7 and later, password prompting is automatic if the server requests a password after a connection has been established.</td>
</tr>
<tr>
<td><code>-?</code></td>
<td>Displays a help message.</td>
</tr>
</tbody>
</table>

Several more options are available in addition to those listed in Table 21.2. See the `psql`’s man page for details on all the available options.

Graphical Clients

If you’d rather interact with a database by using a graphical database client than with the command-line clients discussed in the previous section, you’re in luck: A few options are available.

MySQL has an official graphical client, called MySQLGUI. MySQLGUI is available in both source and binary formats from the MySQL website at www.mysql.com.

Web-based administration interfaces are also available for MySQL and PostgreSQL. phpMyAdmin and phpPgAdmin are two such products. Both of these products are based on the PHP-embedded scripting language and therefore require you to have PHP installed. Of course, you also need to have a web server installed.

### RELATED UBUNTU AND DATABASE COMMANDS

The following commands are useful for creating and manipulating databases in Ubuntu:

- `createdb`—Creates a new PostgreSQL database
- `createuser`—Creates a new PostgreSQL user account
dropdb—Deletes a PostgreSQL database
.dropuser—Deletes a PostgreSQL user account
.mysql—Interactively queries the mysqld server
.mysqladmin—Administers the mysqld server
.mysqldump—Dumps or backs up MySQL data or tables
.psql—Accesses PostgreSQL via an interactive terminal

Reference

- www.mysql.com—This is the official website of the MySQL database server. Here you can find the latest versions as well as up-to-date information and online documentation for MySQL. You can also purchase support contracts here. You might want to look into this if you will be using MySQL in a corporate setting. (Many corporations balk at the idea of using software for which the company has no support contract in place.)

- http://drizzle.org/Home.html—The home page for Drizzle, a fork of MySQL.

- http://kb.askmonty.org/v/MariaDB—The home page for MariaDB, another fork of MySQL made by one of the founders of MySQL.

- www.postgresql.org—This is the official website of the PostgreSQL database server.
The Lightweight Directory Access Protocol (LDAP, pronounced ell-dap) is one of those technologies that, while hidden, forms part of the core infrastructure in enterprise computing. Its job is simple: It stores information about users. However, its power comes from the fact that it can be linked into dozens of other services. LDAP can power login authentication, public key distribution, email routing and address verification; more recently, it has formed the core of the push toward single-sign-on technology.

**TIP**

Most people find the concept of LDAP easier to grasp when they think of it as a highly specialized form of database server. Behind the scenes, Ubuntu uses a database for storing all its LDAP information; however, LDAP does not offer anything as straightforward as SQL for data manipulation!

OpenLDAP uses Sleepycat Software’s Berkeley DB (BDB), and sticking with that default is highly recommended. However, alternatives exist if you have specific needs.

This chapter looks at a relatively basic installation of an LDAP server, including how to host a companywide directory service that contains the names and email addresses of employees. LDAP is a client/server system, meaning that an LDAP server hosts the data, and an LDAP client queries it. Ubuntu comes with OpenLDAP as its LDAP server, along
with several LDAP-enabled email clients, including Evolution and Mozilla Thunderbird. We cover all three of these applications in this chapter.

Because LDAP data is usually available over the Internet—or at least your local network—it is imperative that you make every effort to secure your server. This chapter gives specific instruction on password configuration for OpenLDAP, and we recommend you follow our instructions closely.

**Configuring the Server**

If you have been using LDAP for years, you will be aware of its immense power and flexibility. On the other hand, if you are just trying LDAP for the first time, it will seem like the most broken component you could imagine. LDAP has specific configuration requirements, is vastly lacking in graphical tools, and has a large number of acronyms to remember. On the bright side, all the hard work you put in will be worth it because, when it works, LDAP will improve your networking experience immensely. You should read the entire chapter and understand it before you start. Then, we recommend you read the README file in `/etc/ldap/schema` before you do anything.

The first step in configuring your LDAP server is to install the client and server applications. Install the `slapd` and `ldap-utils` packages from the Ubuntu repositories. This will also install three other packages: `odbcinst`, `odbcinstdebian2`, and `unixodbc`.

By default, Ubuntu configures `slapd` with the minimum options necessary to run the daemon. We are going to configure everything from that bare-bones installation up to where it will be useful.

Now we need to know the fully qualified domain name (FQDN) of your server. In a moment we will begin to write/modify some configuration files, and this will be a vital part of that process. Let’s use matthewhelmke.com. Whenever you see this, change it to your FQDN.

From the FQDN we acquire our domain component, which is the name of your domain as stored in DNS. This is abbreviated using dc. LDAP considers each part of a domain name (separated by a dot) to be domain components. In our example, there are two dc items: matthewhelmke and com.

OpenLDAP now uses a separate directory containing the `cn=config` Directory Information Tree (DIT) to configure the `slapd` daemon dynamically. This allows for modifying schema definitions, indexes, and so on without stopping and restarting the service, as was required in earlier versions. Two files are needed for this configuration: a back end that has only a minimal configuration, and a front end that uses a traditional format that is compatible with and accessed by external programs using established standards.

**Creating Your Schema**

We will start by loading some premade schema files. This makes configuration faster and easier by preloading some settings. If you are building an enterprise server, you should read the official OpenLDAP documentation and start from scratch so that you know
precisely what everything on your server is doing and why. For our example, load these three files into the directory using these commands:

```
$ sudo ldapadd -Y EXTERNAL -H ldapi:/// -f /etc/ldap/schema/cosine.ldif
$ sudo ldapadd -Y EXTERNAL -H ldapi:/// -f /etc/ldap/schema/nis.ldif
$ sudo ldapadd -Y EXTERNAL -H ldapi:/// -f /etc/ldap/schema/inetorgperson.ldif
```

Next, we create a file called `backend.matthewhelmke.com.ldif` with these contents:

```
# Load dynamic backend modules
dn: cn=module,cn=config
objectClass: olcModuleList
cn: module
olcModulepath: /usr/lib/ldap
olcModuleload: back_hdb

# Database settings
dn: olcDatabase=hdb,cn=config
objectClass: olcDatabaseConfig
objectClass: olcHdbConfig
olcDatabase: {1}hdb
olcSuffix: dc=matthewhelmke,dc=com
olcDbDirectory: /var/lib/ldap
olcRootDN: cn=admin,dc=matthewhelmke,dc=com
olcRootPW: changeMEtoSOMETHINGbetter
olcDbConfig: set_cachesize 0 2097152 0
olcDbConfig: set_lk_max_objects 1500
olcDbConfig: set_lk_max_locks 1500
olcDbConfig: set_lk_max_lockers 1500
olcDbIndex: objectClass eq
olcLastMod: TRUE
olcDbCheckpoint: 512 30
olcAccess: to attrs=userPassword by dn="cn=admin,dc=matthewhelmke,dc=com" write by anonymous auth by self write by * none
olcAccess: to attrs=shadowLastChange by self write by * read
olcAccess: to dn.base="" by * read
olcAccess: to * by dn="cn=admin,dc=matthewhelmke,dc=com" write by * read
```

Make sure you change all instances of matthewhelmke and com to fit your FQDN and change the entry for `olcRootPW` to a more secure password of your choosing. Then, add the new file to the directory (I am assuming you are entering this command from the directory where the file was created).

```
$ sudo ldapadd -Y EXTERNAL -H ldapi:/// -f backend.example.com.ldif
```
Populating Your Directory

The back end is ready. Now we need to populate the front-end directory to make this useful. Create another file called `frontend.matthewhelmke.com.ldif` with the following contents:

```ldif
# Create top-level object in domain
dn: dc=matthewhelmke,dc=com
objectClass: top
objectClass: dcObject
objectClass: organization
o: Example Organization
dc: Example
description: LDAP Example

# Admin user.
dn: cn=admin,dc=matthewhelmke,dc=com
objectClass: simpleSecurityObject
objectClass: organizationalRole
cn: admin
description: LDAP administrator
userPassword: changeMEtoSOMETHINGbetter

dn: ou=people,dc=example,dc=com
objectClass: organizationalUnit
ou: people

dn: ou=groups,dc=matthewhelmke,dc=com
objectClass: organizationalUnit
ou: groups

dn: uid=john,ou=people,dc=matthewhelmke,dc=com
objectClass: inetOrgPerson
objectClass: posixAccount
objectClass: shadowAccount
uid: matthew
sn: Helmke
givenName: Matthew
cn: Matthew Helmke
displayName: Matthew Helmke
uidNumber: 1000
gidNumber: 10000
userPassword: changeMEtoSOMETHINGbetter
gecos: Matthew Helmke
loginShell: /bin/bash
homeDirectory: /home/matthew
shadowExpire: -1
```
shadowFlag: 0
shadowWarning: 7
shadowMin: 8
shadowMax: 999999
shadowLastChange: 10877
mail: matthew@matthewhelmke.com
postalCode: 85711
l: Tucson
o: Example
mobile: +1 (520) xxx-xxxx
homePhone: +1 (520) xxx-xxxx
title: System Administrator
postalAddress: I'm not putting it in the book.
initials: MH

dn: cn=example,ou=groups,dc=example,dc=com
objectClass: posixGroup
cn: example
gidNumber: 10000

Remember to change the details to fit your information. Then, we add this to the LDAP directory:

$ sudo ldapadd -x -D cn=admin,dc=example,dc=com -W -f frontend.example.com.ldif

To check that our content has been added to the LDAP directory correctly, we can use:

ldapsearch.

$ ldapsearch -xLLL -b "dc=example,dc=com" uid=john sn givenName cn

dn: uid=matthew,ou=people,dc=matthewhelmke,dc=com
cn: Matthew Helmke
sn: Helmke
givenName: Matthew

In this example, dn stands for distinguished name, uid refers to user identification, ou tells us the organizational unit, dc represents domain component, cn is common name, sn is the family or surname, and many cultures know givenName as your first name.

When you use LDAP, you can organize your data in many ways. You can use a number of currently existing schemas, such as in the previous example using the .ldif files we loaded at the start, or you can write your own. The /etc/ldap/schemas directory has many fine examples in the files with a .schema suffix and a few that have been converted to .ldif format. To be used, the file must be in the LDAP Data Interchange Format (LDIF, or when used as a file suffix, .ldif). You can convert one of the example schemas or create your own schema.
Configuring Clients

Although Ubuntu comes with a selection of email clients, there is not enough room here to cover them all. So, we discuss the two most frequently used clients: Evolution, the default, and Thunderbird. Both are powerful messaging solutions and so both work well with LDAP. Of the two, Thunderbird seems to be the easier to configure. We have had various problems with Evolution in the past in situations where Thunderbird has worked the first time.

Evolution

To configure Evolution for LDAP, click the arrow next to the New button and select Address Book. A new screen appears; its first option prompts you for the type of address book to create. Select On LDAP Servers.

For Name, just enter Address book, and for Server, enter the IP address of your LDAP server (or 127.0.0.1 if you are working on the server), as shown in Figure 22.1. Leave the port as 389, which is the default for slapd. Switch to the Details tab, and set Search Base to be the entire DN for your address book—for example, ou=People,dc=matthewhelmke,dc=com. Set Search Scope to be Sub so that Evolution will perform a comprehensive search. To finish, click Add Address Book.

FIGURE 22.1 Configuring Evolution to use LDAP for addresses is easy for anonymous connections.
Thunderbird

Thunderbird is a little easier to configure than Evolution and tends to work better, particularly with entries that have multiple CNs. To enable, go to the Edit menu, click Preferences, and then select Composition from the tabs along the top.

From the Addressing subtab, check the Directory Server box and click the Edit Directories button to its right. From the dialog box that appears, click Add to add a new directory. You can give it any name you want because this is merely for display purposes. As shown in Figure 22.2, set the Hostname field to be the IP address of your LDAP server (or 127.0.0.1 if you are working on the server). Set the Base DN to be the DN for your address book (for instance, ou=People,dc=matthewhelmke,dc=com), and leave the port number as 389. Click OK three times to get back to the main interface.

FIGURE 22.2 Thunderbird's options are buried deeper than Evolution's, but it does allow you to download the LDAP directory for offline use.

Administration

After you have your LDAP server and clients set up, they require little maintenance until something changes externally. Specifically, if someone in your directory changes jobs, changes her phone number, gets married (changing her last name [surname]), quits, or so forth, you need to be able to update your directory to reflect the change.

We installed some useful utilities with the ldap-utils package earlier. Here are what they do. Each one requires administration privileges, so use sudo.

- 1ldapsearch—Opens a connection to an LDAP server and searches its directory for requested information
- 1ldapmodify—Opens a connection to an LDAP server and allows you to add or modify entries
ldapadd—Opens a connection to an LDAP server and allows you to add an entry

ldapdelete—Opens a connection to an LDAP server and allows you to delete one or more entries

None of these are simple to use, but all come with moderate amounts of documentation in their man pages.

A much smarter option is to use phpLDAPadmin, which is an LDAP administration tool that allows you to add and modify entries entirely through your web browser. The program is available in the Ubuntu software repositories as phpldapadmin.

Starting, stopping, or restarting the slapd daemon is done in the usual way for system daemons (that do not yet have Upstart methods written for them).

```
sudo /etc/init.d/slapd start/stop/restart
```

The Linux Terminal Server Project (LTSP) is an add-on package for Linux that allows you to run multiple thin clients, low powered terminals, from one main server. A thin client is a small, energy-efficient, and generally lower powered system designed to be used in conjunction with a more powerful server. The thin client will have limited processing power and speed and limited storage, making it very inexpensive. All it is used for is receiving input from a device such as a keyboard or mouse, communicating with a server, and displaying output to a screen.

Processing of information and the actual running of programs are offloaded to the server, meaning the server does all the hard work and is the only system in the network that has strong requirements for processor power and speed, memory, storage, and so on. Thin clients are also generally smaller in size and quieter, which also make them more convenient to use when space and noise are potential issues. Those of us who have been around longer or who have worked in enterprise environments will see an immediate relationship to big metal servers and dumb client terminals, and it is reasonable to think of an LTSP setup this way. In our case, the server isn’t as big or as powerful and the thin clients aren’t as dumb and weak, but the idea is the same.

Thin clients are great in places such as classrooms and computer labs where strict control and strong security are desirable, where money for a room of full-powered systems may not be available, and where installing and maintaining core software on one server is preferable to doing so on many systems. For this reason, Edubuntu, a community led official sub-project of Ubuntu, is designed for easy LTSP
installation and configuration. We will focus on using LTSP with standard Ubuntu, but if you want to use LTSP in an education-specific context, or if you just want an additional perspective and more information about LTSP, Edubuntu is worth a closer look. Other common places you are likely to find thin clients in use are libraries for catalog access and searches and in some airports that make courtesy terminals for checking email available for travelers.

Links to several thin client hardware sources are included in Reference, although they are included to inform and should not be taken as endorsements—we don’t own and have not used equipment from every company listed and can’t make any honest recommendations about them. In addition to those mentioned, you are sure to find others. In fact, computers that often make excellent thin clients are not advertised as such. You can look for compact format systems that use an ARM, VIA, or maybe an Intel Atom processor, for example, and are likely to find they make wonderful thin clients. You can even recycle older hardware that would otherwise be bound for the dustbin and make it useful again as a thin client.

Now that you have a sense of why you might use LTSP and how the network is created, it is a good time to fill you in on some of the details of what LTSP is, what it is not, and how it is designed to work. Armed with this knowledge, you will be able to find documentation to help you decide what you can afford to buy, how you want to configure it, and even whether this is a configuration that is applicable and useful to your situation.

LTSP is add-on software for Linux that creates a server that can be used to boot client computers over a network. It allows them to access and run applications on the server while the client remains responsible for input and display and the server handles processing data and storage. This allows many inexpensive hardware clients to be used to do things that would normally be beyond the capability of the hardware and streamlines administration by placing all the configuration and software on one server. The biggest limitations will result from server and networking hardware (for example, switch or hub, 1GB versus 100 MB ports, high-end server and storage or less expensive just-adequate equipment).

**Requirements**

Our minimum recommended specifications for thin clients are a processor running at 400MHz with 128MB RAM and the ability to boot via PXE (a common network boot protocol). Nearly any system sold today and advertised as a thin client will exceed these requirements by a wide margin. We list them here in case you want to try to reuse old hardware that is otherwise obsolete. Server and other hardware recommendations are listed in the Installation section.

Let’s start by looking at several wiring schemes to show appropriate methods of using LTSP. The first one, shown in Figure 23.1, is the default install without an Internet connection and is the simplest way to use LTSP.
From the diagram alone you can see the main pieces of hardware needed: a server, a switch/hub, and a number of thin clients. The switch/hub is the first piece of hardware we discuss.

For simplicity we only show four thin clients in each example, but this is not an actual limit. The number of thin clients is limited by your switch/hub and even an inexpensive hub will support four connections, although it is common for quality enterprise-grade switches to have 48 or more ports. A switch is generally faster and more expensive than a hub and is often preferable for reasons beyond the scope of this chapter, but they both serve the same basic purpose and either can work in an LTSP setting. They are used to control traffic on a network and make sure that communication happens between computers as it is intended.

Ideally, you want a piece of hardware here that will support a GB connection between the server and a switch, with at least 100MB connections between the thin clients and the switch, and enough unused communication ports to make future expansion easy without requiring the addition of another switch or hub and layer of complexity. If money is an issue and ideal performance isn’t vital, an inexpensive hub that only had 100MB ports all around and just enough ports to connect everything will certainly work. If you are connecting more than 10 clients to the server, a GB connection to the server is strongly recommended. Life is full of trade-offs and money supplies are not limitless, so use your best judgment and buy the best you can afford.

For the server, recommended specifications depend greatly on the intended use. If everyone will be using the same program on each client, you do not need as much memory and processor speed as you would if everyone is doing different things at the same time. You can easily run LTSP server on a repurposed old machine you have sitting around with 512MB RAM, a 1GHz Celeron processor, and a decent, working hard drive, and it will
work, but we don’t really recommend that if you are going to have more than a couple of clients doing anything beyond simple and identical tasks.

Our minimum recommendation is the same as the current recommendation for a minimum Ubuntu desktop installation: a 1GHz x 86 processor, 1GB RAM, a 15GB hard drive. At least a 100MB ethernet card is vital. Ideally, you would bump each category up to the highest level you can afford and expect better performance as a result. Our minimum-if-you-want-a-great-experience recommendation is a current-issue fast-as-you-can-afford multicore 64 bit processor, 4GB RAM, at least two fast hard drives in a RAID array for performance and data backup, and at least one and perhaps two GB ethernet cards.

Most of the time you use LTSP you will want the network to be connected to the Internet. There are two main ways to do this. Figure 23.2 shows the network with an Internet connection via an Internet router connected to the switch/hub. This is a common method and will work well.

Another common method is to connect the server directly to the Internet router as in Figure 23.3. This has the benefit of allowing you to easily configure and use the server as a gateway to control thin client access to the Internet. To do this, the server must have two network cards, and we again recommend that the one used to connect to the switch is a 1GB card; all the thin client traffic has to travel between the switch and server over that one connection, so this will cause fewer bottlenecks than if you have multiple clients connecting to a switch at 100MB trying to share a single 100MB connection to a server. The card from the server to the Internet router should be adequate for the Internet.
connection available, but there is no reason to put anything faster in there. If you have only a 100MB connection with your Internet service provider, using a 1GB card will not give any particular benefit.

After you decide how you want to set up your network and connect all the hardware, you can get to the task of installing the software. In Ubuntu, the LTSP software is available for installation in two ways. If you are repurposing a server that already has a current release of Ubuntu installed on it, you install the `ltsp-server-standalone` and `openssh-server` packages from the Ubuntu repositories and run the following to set up the environment:

```
matthew@seymour:~$ sudo ltsp-build-client
```

If your server is a 64-bit system and your thin clients use a different processor architecture, you want to run that command with the `--arch` option, as in

```
matthew@seymour:~$ sudo ltsp-build-client --arch i386
```

Most people will be installing from scratch and not reusing a system with Ubuntu already installed. This is still quite easy. You will need to download the alternate install CD from the Ubuntu website at http://releases.ubuntu.com/. From here, find the release version of Ubuntu you want to use for the server. Some will want the current release (at this writing, 10.10) and some will want to use an LTS release like 10.04 LTS. Click the release version you want to use and then find the link for the alternate install CD for your server’s processor architecture, either 32-bit or the 64-bit. Download it and burn the image to a CD as discussed in Chapter 1, “Installing Ubuntu.”
Make sure all your thin clients are connected and set to boot from network using PXE, but turned off. Then boot the server using the alternate CD, press F4 for the modes menu, and choose Install an LTSP Server. A regular Ubuntu installation will begin. Near the end of the installation a message will appear that lets you know the thin client system is being built on the server. You will be notified that it is being compressed into an image, and when the process is complete you will reboot your server, removing the CD at the appropriate moment in the process.

After the server has rebooted and is running, you may turn on your thin clients and they will boot from the network using the image on the server. Thin clients will be able to run any programs installed on the server.

**Using LTSP**

When you boot a thin client in an LTSP network, it retrieves the boot image from the LTSP server and uses it to create the environment to be displayed to the user. The process includes using DHCP to request from and assign to the client an IP address on the network, downloading the kernel and initial RAM disk from the server, then downloading the LTSP configuration and mounting the server-hosted file system, using chroot to use this file system as the client’s own root file system, and then finishing the boot using the instructions in that file system. This is a highly configurable process. By default the client boots to a login screen using the LTSP Display Manager (LDM) in place of GDM that is used by Ubuntu, KDM that is used by Kubuntu, or others. User accounts are used to limit or control access, and the LDM initializes the details for communication between the server and client, including launching the desktop, mounting storage devices and home directories, and creating menu items. The entire desktop is run on the server and displayed on the client.

By default, LTSP uses inherent abilities in Linux but has configured them to work together smoothly. Details may be modified to suit your needs. For example, communication between an application server and a client is done by tunneling an X11 session over ssh, making the sharing of a graphical desktop easy and using a standard method while also being a secure method of communicating user credentials.

One really useful feature in LTSP is that you are not limited to using only one server in a network. If your network of thin clients grows to a point where your current server is being taxed, there is an easy way to configure and add a second or multiple servers to the network to share the load. In this case, the server that a thin client uses to boot is not necessarily the same server that a user will log in to. When you add servers, one server is chosen to be the primary server and controls thin client boots, data storage, and runs additional services. Additional, secondary servers can be much simpler because all they do is host desktop sessions and will be configured to use the central services from the primary server for everything else. In a multiple server network, authentication of users is something that you will need to think through and configure as it becomes a little more complex. There are many ways to do this, including the obvious choice, LDAP.
Creating and maintaining an LTSP network is very useful in specific situations and can be a cost-effective way of using administrator time while providing useful functionality to end users. Although the foundation sounds simple in this introductory chapter, it can be a complex task worthy of an entire book. Our intent with this chapter is to give enough information for you to determine whether LTSP is a technology that will suit your needs and is deserving of a closer look. To that end, we offer several useful links in the Reference section and suggest them as your next step.

Reference

- https://help.ubuntu.com/community/UbuntuLTSP—The Ubuntu community documentation page is easily the best resource for LTSP because it includes an organized and up-to-date set of links to information on any aspect you should need.
- http://edubuntu.com/—The leaders of the Edubuntu community project are very knowledgeable about LTSP and helpful. This site is a great place to start when you are looking for people with experience to help you with questions.

A sampling of companies advertising thin clients:

CHAPTER 24

Ubuntu in the Cloud

Cloud computing allows you to build large, flexible systems for on-demand processing of data. When your requirements are low, you use few resources. As the need arises, your processes scale to use multiple systems with optimized performance according to the requirements of the moment. This is an efficient way to utilize hardware and minimize waste.

To accomplish this feat of computer engineering, a special network is set up using on-demand virtual systems that consume resources only as needed and release those resources for use by others when they are not in use. Virtualization is the technology that enables this concept. This may be accomplished using third-party virtualization platforms like VMware, VirtualBox, Parallels, and others. Ubuntu has another option to offer, the Ubuntu Enterprise Cloud, which is the main focus of this chapter.
Much of what we discuss here is possible using other forms of virtualization, such as those mentioned previously. What makes Ubuntu Enterprise Cloud unique is that the virtualization is done using KVM, the Kernel-based Virtual Machine that is a part of the Linux kernel, and the capabilities of modern processors containing virtualization extensions in a way that allows easy installation, deployment, integration, and configuration. Canonical certifies Ubuntu on a wide range of equipment from multiple manufacturers and guarantees that Ubuntu Enterprise Cloud will work on them, just as it works with other virtualization providers.

Why a Cloud?

Businesses and enterprises have built computer networks for years. There are many reasons, but usually networks are built because specific computation or data processing tasks are made easier and faster using more than one computer. The size of the network generally depends on the tasks that need to be done. Building a network usually entails taking a detailed survey of needs, analyzing those requirements, and gathering together the necessary hardware and software to fulfill those needs now, perhaps with a little room for growth if money permits.

Cloud computing is designed to make that easier by providing resources such as computing power and storage as services on the Internet in a way that is easy to access remotely, available on demand, simple to provision and scale, and highly dynamic. In the ideal case, this saves both time and money. Hardware, storage, networks, and software are abstracted as services instead of being manually built and configured and are then accessed locally on demand when the additional resources are required. Sometimes these abstractions are referred to as Infrastructure as a Service (IAAS), Platform as a Service (PAAS), and Software as a Service (SAAS).

Some of the greatest benefits are the ease with which new resources may be added to a cloud, the fault tolerance inherent in the built-in redundancy of a large pool of servers, and the payment schedules that charge for resources only when they are used. There is also a great benefit in abstracting the complexity out of the process; clients perform the tasks they want to perform, and the cloud computing platform takes care of the details of adding resources as needed without the end user being aware of the process. Virtual machines are created and used when needed and destroyed immediately after they are no longer needed, freeing up system resources for other purposes.

UEC and Eucalyptus

Ubuntu Enterprise Cloud (UEC) is a stack of applications from Canonical that are included in the Ubuntu Server Edition. These applications make it very easy to install and configure an Ubuntu-based cloud. The software is free and open source, but Canonical offers paid technical support.
UEC is based primarily on Eucalyptus, which is GPL software written to provide cloud computing and cloud storage platforms that are both free (as in freedom and as in beer) and completely compatible with Amazon’s EC2 cloud computing and S3 cloud storage platforms. The Eucalyptus services are available through APIs that are compatible with EC2/S3, so client tools written for the Amazon Web Services (AWS) can also be used with Eucalyptus.

An Ubuntu Enterprise Cloud consists of several components. We start with a node, which is a server that is capable of running KVM as its hypervisor. A hypervisor is software that allows multiple virtual machines to run on one piece of hardware by presenting each virtual machine with a virtual platform and monitors each virtual machine for performance, resource use, and needs. This allows multiple operating systems to share hardware resources. Other hypervisors are available, such as Xen, but Ubuntu has chosen KVM as the default.

The next components are the Node Controller (NC) and the Cluster Controller (CC). The NC runs on each node and controls all virtual machines running on that node. The NC runs as a layer between the host operating system and the CC above it, serving as a go-between that queries the operating system to discover physical resources available and the state and number of virtual machines running on the node and reports this information to the CC. The CC then manages the networking for the instances running on that and other nodes and makes sure that the Cloud Controller (CLC) gets that information.

The Cloud Controller is the main front end to the whole cloud. It provides the API for client services and deals with all requests and responses, communicating via web services between the client tool and the UEC components. The CLC also provides a web interface for managing parts of the infrastructure. This is where resource availability is monitored and managed.

Two other controllers are in the interface, the Storage Controller (SC) and the Walrus Storage Controller (WS3). The SC provides a way to create persistent storage devices similar to Amazon’s Elastic Block Storage (EBS) devices, which are block storage devices that are created separately from cloud computing instances and are intended to be highly reliable, highly available, and accessible. The WS3 is a simple storage service that uses REST and SOAP APIs that are compatible with Amazon’s S3 APIs and that serve to store virtual machine images, snapshots, and store and serve files.

This highly complex system is illustrated in Figure 24.1.

**Deploy/Install**

There are two ways to deploy UEC: on a private cloud or on a public cloud. Both have benefits and drawbacks. This section presents the things you need to consider when choosing. We also look at a way to mix the two.

A public UEC is built on Amazon’s EC2. This means your local hardware requirements are minimal, your startup costs are low, deployment is quick, and growth is easy. The drawback to working this way is that you do not physically control the hardware on which
your cloud is running. For many this is a benefit, but this may not be suitable for high security needs. Although you alone control the software and processes on your public cloud, there may be some worry about who has access to the machines. While Amazon would not last long in business if their data centers and machines were not secure, there are some applications and data that are so sensitive you cannot afford to allow any outside risk. There are also legal constraints, such as from the Sarbanes-Oxley Act, that sometimes force IT policy decisions in an organization and make the public option impossible.

A private UEC is created on hardware you own and control. This requires a large upfront commitment, but you have the security of running everything behind a company firewall and with complete knowledge of who is able to physically access your machines and who is listening on the network.

One thing to consider is the possibility of starting your UEC as a private cloud and then creating interfaces from there to public services. Perhaps you prefer to keep all your data stored on the private cloud, but you want to use some services and applications on a
public cloud. This is an avenue worth exploring if your company has a mixture of “must be secured and held in-house” and “we still want to keep it away from prying eyes, but if something happens it won’t be catastrophic” needs. The big issue with this method is moving data between public and private servers; if you have large amounts of data, this can be prohibitive. As always, do your due diligence.

**Public**

Deploying a public cloud on Amazon’s servers is quick and easy. First, go to [http://aws.amazon.com/](http://aws.amazon.com/) and sign up for an account. Then, while logged in, go to Your Account, Security Credentials, and define the security settings to manage and access your service.

Next, you need a tool to allow you to start and stop instances. There are several, but we will focus on two. One is Euca2ools, which are a set of command-line tools from Eucalyptus for interacting with the Amazon EC2 and S3 services via web services. These are installed by default with Ubuntu Server; you can learn more about using them in the Euca2ools User Guide from the link provided in the Reference section. We cover the basic commands for Euca2ools later in this chapter. The other tool is a paid service from Canonical called Landscape. It provides a web-based graphical user interface for interacting with the Amazon cloud services and for managing your UEC. It works with both public deployments on Amazon and private installations on your own equipment. A link to Canonical’s website for Landscape is also in the References section.

After your tool is in place, you use it to choose and start your machine instances. You will also use this tool to manage the instances later. Many Ubuntu virtual machine images have already been published to Amazon EC2 and are immediately available for deployment. You can find a list at [http://uec-images.ubuntu.com/releases/](http://uec-images.ubuntu.com/releases/) under the specific Ubuntu release you are interested in using.

The final step is to access your instances to set up the applications you want to provide on your cloud. You will manage your cloud using the tools mentioned earlier.

**Private**

Installing UEC on your own machines is more complicated, even though the needs are the same. Much of the complexity is dealt with by Amazon when deploying on its servers. Before you start, you will need to check that you have the hardware required. At a minimum, you will need two servers. One will serve as a front end, and you need one or more nodes.

For the front end, or any system that will run one or more of these, the CLC, the CC, the WS3 and/or the SC, the basic requirements shown in Table 24.1 must be met.
For nodes, which will run the node controller and instances, you need to meet the requirements shown in Table 24.2.

**TABLE 24.2 Requirements for the Node Controller and Instances**

<table>
<thead>
<tr>
<th>Hardware</th>
<th>Minimum</th>
<th>Suggested</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>VT exten-</td>
<td>VT, 64-bit, Multicore</td>
<td>64-bit can run both i386 and amd64 instances; by default, Eucalyptus will run only 1 VM per CPU core on a node.</td>
</tr>
<tr>
<td>Memory</td>
<td>1GB</td>
<td>4GB</td>
<td>Additional memory means more and larger guests.</td>
</tr>
<tr>
<td>Disk</td>
<td>5400rpm IDE</td>
<td>7200rpm SATA or SCSI</td>
<td>Eucalyptus nodes are disk intensive; I/O wait will likely be the performance bottleneck.</td>
</tr>
<tr>
<td>Disk Space</td>
<td>40GB</td>
<td>100GB</td>
<td>Images will be cached locally; Eucalyptus does not like to run out of disk space.</td>
</tr>
<tr>
<td>Networking</td>
<td>100Mbps</td>
<td>1000Mbps</td>
<td>Machine images are hundreds of MB and need to be copied over the network to nodes.</td>
</tr>
</tbody>
</table>

When you have confirmed that your equipment meets or exceeds the requirements, download the Ubuntu Server installation disk from http://releases.ubuntu.com/ and click the release version you want to use (for example, 10.04 LTS or 10.10). Make sure you download the server installation CD. Burn it to a disk.

When you boot, select Install Ubuntu Enterprise Cloud. The installer will check and detect whether you have a Eucalyptus cloud controller or other components. Because none are present, you will need to install a cloud controller (CLC) at a minimum. If this is going to be the only front-end system and will be expected to run all the services, make sure you also tell the installer to include the WS3, CC, and SC components.
You will be asked to name your cluster and supply a range of IP addresses on the LAN that UEC will be able to use and allocate to instances. Typically, this is something like 192.168.1.125—192.168.1.240. Allow the installation to complete.

To install node controller(s), make sure each system you intend to use as a node is connected to the network on which the CLC is running. Boot each one at a time to the same server installation CD and again select Install Ubuntu Enterprise Cloud. It should detect the cluster and preselect Node for you. Confirm it and finish the installation as usual. When the node reboots, it will be ready to be registered.

Node registration should be automatic and will include servers exchanging public SSH keys, configuring services properly, services publishing their existence to the rest of the cloud, running the appropriate version of uec-component-listener for components installed, and verifying registration. Instructions for performing these steps manually are available at https://help.ubuntu.com/community/UEC/CDInstall should you discover a failure.

After installing and booting the CLC, users will need credentials. These can be retrieved using a web browser or from the command line. From a web browser, open https://<cloud-controller-ip-address>:8443/. You must use a secure connection, but you will receive a security certificate warning. You need to add an exception to view the page. If you do not, you will not be able to view the Eucalyptus configuration page.

Use the username “admin” and password “admin” the first time you log in. Follow the onscreen instructions to change the admin password as required and enter a valid email address for the admin. Click the Credentials tab, and from there choose Download Credentials. Save the certificates to ~/.euca and unzip.

You may also retrieve your credentials from the command line. Create ~/.euca and enter that directory; then enter:

```
matt@seymour:~.euca$ sudo euca_conf --get-credentials mycreds.zip
```

Unzip them and create this link:

```
matt@seymour:~.euca$ ln -s ~/.euca/eucarc ~/.eucarc
```

Next, you need to set up the EC2 API and AMI tools on your server. Check that euca2ools package is installed. If it is, you can get the local cluster availability details this way:

```
matt@seymour:~.euca/eucarc$ euca-describe-availability-zones verbose
```

<table>
<thead>
<tr>
<th>AVAILABILITYZONE</th>
<th>myowncloud</th>
<th>192.168.1.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVAILABILITYZONE</td>
<td></td>
<td>- vm types</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- m1.small</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- c1.medium</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- m1.large</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- m1.xlarge</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- c1.xlarge</td>
</tr>
</tbody>
</table>

If everything looks correct, you can start installing images. The easiest way to do this is from the store using the web interface. Access the interface as you did earlier using
https://<cloud-controller-ip-address>:8443/ and this time click the Store tab. You will see a list of available images to download and install. Information is also given here about how to run images.

To run an image from the command line, you first need to create a key pair that you can use to log in to that instance as root. Here is an easy way to do that:

```
if [ ! -e ~/.euca/secretkey.priv ]; then
    mkdir -p -m 700 ~/.euca
    touch ~/.euca/secretkey.priv
    chmod 0600 ~/.euca/secretkey.priv
    euca-add-keypair secretkey > ~/.euca/secretkey.priv
fi
```

You can call your key anything you want, and if you forget what keys exist you can run `euca-describe-keypairs` to get a list of created keys stored on the system. You then have to allow access to port 22 in each of your instances using:

```
matthew@seymour:~.euca/eucarc$ euca-authorize default -P tcp -p 22 -s 0.0.0.0/0
```

Then you can create instances of your registered image using:

```
matthew@seymour:~.euca/eucarc$ euca-run-instances $EMI -k mykey -t m1.small
```

You may have more than one instance of the same image. The first time you run an instance, the system will take a while to start up because it will set up a cache of the image. VM images are quite large. You can watch to see if it is up using:

```
matthew@seymour:~.euca/eucarc$ watch -n5 euca-describe-instances
```

When the status changes from pending to running, you want to make a note of the IP address assigned to the instance and connect to it using:

```
matthew@seymour:~.euca/eucarc$ IPADDR=$(euca-describe-instances | grep $EMI | grep running | tail -n1 | awk '{print $4}')
matthew@seymour:~.euca/eucarc$ ssh -i ~/.euca/mykey.priv ubuntu@$IPADDR
```

When you are done, you can exit your SSH connection and terminate your instance using:

```
matthew@seymour:~.euca/eucarc$ INSTANCEID=$(euca-describe-instances | grep $EMI | grep running | tail -n1 | awk '{print $2}')
matthew@seymour:~.euca/eucarc$ euca-terminate-instances $INSTANCEID
```

## A Euca2ools Primer

Most uses for cloud computing involve custom tools and software by people who know how to read an API and make their program interact without bothering end users with the details. It is no different with UEC. For that reason, we will list some of the commands from euca2ools without a lot of commentary.

Euca2ools contains many commands for managing your resources. Most have numerous configuration options available. After the euca2ools package is installed, the man pages for each command provide valuable information about how to use them. Following is a
simple list to help you remember what commands do so that you can look up the details of how to use them:

- `euca-bundle-image`—Bundles an image for use with Eucalyptus, UEC, or Amazon EC2
- `euca-bundle-vol`—Bundles the local file system of a running instance as a bundled image
- `euca-delete-bundle`—Deletes a previously uploaded bundle
- `euca-download-bundle`—Downloads a bundled image from a bucket
- `euca-unbundle`—Unbundles a previously bundled image
- `euca-upload-bundle`—Uploads a previously bundled image to the cloud
- `euca-describe-images`—Shows information about machine images
- `euca-describe-image-attribute`—Shows image attributes
- `euca-register`—Registers a manifest for use with the cloud
- `euca-deregister`—Deregisters an image from the cloud
- `euca-describe-instances`—Shows information about instances
- `euca-reboot-instances`—Reboots specified instances
- `euca-run-instances`—Starts instances
- `euca-terminate-instances`—Stops specified instances
- `euca-confirm-product-instance`—Confirms if instance is running with product code supplied
- `euca-attach-volume`—Attaches a volume to an instance
- `euca-create-volume`—Creates a volume in the specified availability zone
- `euca-delete-volume`—Deletes a volume
- `euca-describe-volumes`—Shows information about existing volumes
- `euca-detach-volume`—Detaches a volume from an instance
- `euca-create-snapshot`—Creates a snapshot from an existing volume
- `euca-delete-snapshot`—Deletes a snapshot
- `euca-describe-snapshots`—Shows information about snapshots
- `euca-allocate-address`—Allocates a public IP address
- `euca-associate-address`—Associates an instance with a public IP address
- `euca-describe-addresses`—Shows information about IP addresses
- `euca-disassociate-addresses`—Disassociates a public IP address from an instance
euca-release-address—Releases a public IP address
euca-add-group—Creates a new security group
euca-delete-group—Deletes a security group
euca-describe-groups—Shows information about groups
euca-add-keypair—Creates a new key pair for use with instances
euca-delete-keypair—Deletes a key pair
euca-describe-keypairs—Shows information about key pairs
euca-describe-availability-zones—Shows information about availability zones
euca-describe-regions—Shows information about regions
euca-get-console-output—Prints console output from a running instance
euca-modify-image-attribute—Modifies attributes of an image
euca-reset-image-attribute—Resets attributes for an image
euca-revoke—Revokes a rule for a security group
euca-version—Shows the Euca2ools version
euca-authorize—Adds a new rule to a security group
uec-publish-tarball—Registers a UEC tarball
uec-registration—Enables or disables automatic component registration
uec-run-instances—Same as euca-run-instances
uec-publish-image—Publishes image to bucket
uec-query-builds—Finds information about a build
uec-resize-image—Resizes UEC image

CHAPTER 25
Opportunistic Development

There are some among us who love to write program code. Others are able, but don’t particularly enjoy doing so. Most of this section of the book (Part V: Programming Linux) is dedicated to the first group, those who love to code and want to know how to get started using their favorite tool(s) in Ubuntu. However, it also applies to those of us who just want to scratch a specific itch by coding up a quick program to do something useful and make it available to other Ubuntu users, but who aren’t interested in learning how to become a package maintainer, upload to the official software repositories, and so on. We call this process opportunistic development, where an end user codes up a quick solution to a problem. This is in direct contrast to systematic development, with professional planning, requirements gathering, design, processes and procedures.

We have a couple of links in the Reference section if serious, sustained development and helping with official packaging is your ultimate goal, but to get started, let’s look at an initiative by the Ubuntu community to help scratch that itch—get something written and then make it available to others quickly and easily. This project is quite new and under active development, so what we have here is a short survey to whet your appetite and help you know where to look to get connected and get started.

You have an idea for a program that will save time by automating a repetitive task. You plan for it to have a pretty GUI interface and you think there are probably others out there who would like to use the tool after it is written. The problem is that you work full time, have a family, and already have a ton of side projects that don’t get enough attention. You are either not able or not willing to sit down...
and study how Ubuntu packages programs to get them into the official software repositories. (If you are, see the links in Reference.)

It used to be that you had one simple choice at this juncture: write the program and put it on a website for others to find—and hope that maybe someone would find it useful, make a .deb package, and upload it into either the Debian or Ubuntu repositories. That is no longer the only option if your goal is simply to write your tool and make the software available to Ubuntu users. Now, you still need to be technically proficient at writing whatever code you want to write and understand complex systems, but Ubuntu is lowering the complexity for getting that code written and making it available to the wider community. This allows developers who want only to scratch that one itch to do so without reading tons of documentation about tools they expect to use rarely or only once.

Launchpad

To get started, you need to sign up for an account on Launchpad (Figure 25.1). Launchpad is an infrastructure created to simplify communication, collaboration, and processes within software development. It was developed and is supported by Canonical, the company that supports the Ubuntu community, but it is used by many software projects, including several that are not a part of the Ubuntu community.

Launchpad is where Ubuntu development takes place. It integrates Bazaar, a version control system that makes keeping track of changes to software code much simpler and
permits those changes to be reverted when necessary while tracking who is performing the actions. Launchpad also incorporates Soyuz, which is a distribution and archive management software that handles the automatic package builds within Launchpad.

For developers using Launchpad, this means that the process became a bit simpler. They can concentrate on writing and editing their code and let Launchpad deal with keeping track of the changes and creating their packages. This is useful for active developers who write and maintain big projects that need source code version control and so on. It also hosts bug reporting and tracking, mailing lists, software interface translation, and much more. Most of this is beyond the scope of this chapter but of great interested to the serious developer.

What is of interest to us is that registered Launchpad users can create a personal package archive (PPA). This is a much simpler way to make programs available. Anyone with a PPA can upload source code to be built in to packages. Those packages will then be made available in an apt repository that may be added to any Ubuntu user's list of source repositories and downloaded or removed using any of the standard package management tools in Ubuntu, such as apt, Ubuntu Software Center, and Synaptic. Instructions are included on the web page for each Launchpad PPA, describing how to add that repository, making this an easy method to share software that may be added and removed by even the most nontechnical end user. In Figure 25.2 we show the PPA for the stable version of Google Chromium.

![FIGURE 25.2 A Launchpad PPA for the stable version of Google Chromium.](image-url)
Quickly

Several very knowledgeable and talented Ubuntu developers got together and started talking. These are people who know how to program and who enjoy it. At the same time, they want programming on Linux to be easy and fun and decided that it wasn’t terribly fun for some because it can be so hard to learn. There are so many choices, so many tools, so much documentation to read and study just to get started. They had a “what if” moment: What if we could write a program that makes some very opinionated choices about tools and templates and make that available to new programmers and people who just want to write a quick application and who are not interested in studying every available option before choosing? Not everyone cares about the benefits of Gtk versus Qt, or even knows what those are. Why force uninterested people to make those choices? Quickly is the result of these discussions and is the solution created by some of those developers.

Quickly is a tool to help you write and package software programs (and other things) quickly. You can select from a set of application templates and use some simple quickly commands to create, edit code and GUI, and publish your software for others to use. Quickly’s templates are easy to write. So if you are a fan of language foo, you can create a foo-project template. Or if you want to help people making plug-ins for your killer app, you can make a killer-app plug-in template. You can even create a template for managing corporate documents, creating your awesome LaTeX helpers. Better yet, if you don’t know what some of that means and you just want to make a useful Python tool with a pretty GUI, you can do that quickly with Quickly.

The most popular template is the ubuntu-application template, which is not surprising because the Ubuntu community wrote Quickly and uses it most often so far. This template uses a specific set of tools that are among the most common used for Linux, and specifically Ubuntu, desktop software. They include the following:

- **Python**—An extremely popular, easy-to-learn programming language that we cover in Chapter 28, “Working with Python.”
- **GTK**—A cross-platform toolkit for creating GUI interfaces that is used extensively in the GNOME desktop environment, making it a good fit for easy integration of new programs into the default desktop used by Ubuntu.
- **Glade**—A user interface designer for GTK from the GNOME community. It is powerful and quite easy to use to aggregate all the widgets and windows desired for a project.
- **GStreamer**—A media framework used in GNOME for easy integration of audio and video content in desktop applications.
- **Desktop Couch**—A database format built on Apache’s CouchDB that allows easy integration of powerful database storage, replication, and synchronization in desktop programs. It is used by Ubuntu One and others for cloud storage.
- **gedit**—The default text editor in the GNOME desktop environment.
Using these very common tools by default eliminates many of the more confusing choices developers need to make when creating a new application. Because each of these choices are very common in Ubuntu, in GNOME, and generally throughout the Linux world, an application created using them is almost guaranteed to blend in beautifully with any end user’s desktop.

Quickly is in the Ubuntu repositories as quickly. Quickly is run from the command line. After installation, the best way to get going is to run the tutorial and read some basic information:

```
matthew@seymour:~$ quickly tutorial ubuntu-application
```

Some useful commands for quickly include:

```
matthew@seymour:~$ quickly create ubuntu-application matthewsapplication
```

This creates the initial template for an Ubuntu program called matthewsapplication and a subfolder from which you will work on your project, and you’ll get feedback with a nice pop-up window (Figure 25.3).

```
matthew@seymour:~$ cd matthewsapplication
```

![Figure 25.3 Quickly lets you know your application has been successfully created.](image)

To verify that the application has been created, you can change to the new application’s directory and list its contents.

```
matthew@seymour:~$ cd matthewsapplication
```
Start editing the default GUI for your new app using Glade with

```
matthew@seymour:~$ quickly design
```

This will bring up a beautiful interface to help you create all the actions, containers, widgets, and so on that you need in your application (Figure 25.4).

![FIGURE 25.4 Quickly uses Glade to help you create your user interface.](image)

Change the application behavior and edit your Python code in gedit (Figure 25.5) with

```
matthew@seymour:~$ quickly edit
```

Test your new application by running it with
FIGURE 25.5  Code files open in adjacent tabs for quick and easy editing in gedit.

You can create a package build of your application, which is recommended for testing, using:

```
matthew@seymour:~$ quickly package
```

One of the most exciting features of Quickly is that it integrates with Launchpad to speed up the process of dealing with PPAs. You will need a Launchpad account. There are two equivalent commands for doing this:

```
matthew@seymour:~$ quickly release
```

and

```
matthew@seymour:~$ quickly share
```

If you have a bit more development experience, you can create templates for Quickly, like the ubuntu-application template, that make specific decisions about programming language and much, much more. Quickly is young and in active development, but is already very usable. Check out the links in the Reference section for more information.

**Ground Control**

Collaboration on software can be difficult. The bar for entry into that world is set quite high because of the complexity of the tools. Have you ever had a problem with a program and been able to figure out what was wrong—maybe you've even been able to write a quick software patch for it—but not been able to figure out how to submit that patch to the original developer? It happens. Think of the case where someone discovers a
misspelled word in a bit of Python code and wants to help save a bit of the developer’s time by fixing it.

Ground Control seeks to simplify this and other sorts of collaboration on software projects. It takes the technology and workflows that most developers use and know and makes them available to the Ubuntu desktop where common non-developer end users can use them. It is essentially a version control system built in to the Ubuntu desktop that interacts directly with Launchpad and Bazaar using the standard Ubuntu GNOME file browser. This is also useful when you write the software yourself using Quickly or another method and make it available on Launchpad using a PPA. Then someone comes to you offering a bug fix, someone who may be even less technically proficient with the behind-the-scenes tools.

Install Ground Control (groundcontrol) from the Ubuntu software repositories, from the Ground Control website (https://launchpad.net/groundcontrol), or from the daily build PPA linked from that web page. A program will appear in your menu at System, Preferences, Ground Control Configuration, shown in Figure 25.6, which you need to run to give Ground Control the capability to interact with your Launchpad account. This is also the tool you use to log out when you are done using Ground Control. If you don’t have a Launchpad account, Ground Control will help you sign up for one.

![Launchpad User Configuration](https://example.com/groundcontrol_config.png)

**FIGURE 25.6** Click Login to Launchpad to get started with Ground Control.

When you sign in, Ground Control will get your Launchpad credentials, including your uploaded ssh key, from Launchpad. An ssh key is a special code needed for secure connections; it identifies you personally so that the systems and others using it can be confident of who uploaded the code. You can use an existing ssh key that you have uploaded to your Launchpad account. If you do not have an ssh key, Ground Control will help you create one. Ground Control will then update your local Bazaar configuration automatically.

Then, when you use the GNOME file browser (aka Nautilus) to view a directory that is related to a Bazaar branch you have previously used, it will give you tools to interact with it. After you have run the Ground Control Configuration tool the first time, you will
discover a new folder in your home folder called Projects. From now on, if you want to log in to Ground Control, you can also do so in that folder by clicking the Identify Yourself button, as shown in Figure 25.7.

After you are logged in, you will see the confirmation box (Figure 25.8) and notice a change in the file manager. You now have buttons labeled Fix Bug and Fetch Project (Figure 25.9).

If you click Fetch Project, you are taken to a search window. Enter the name of a project you want to find, and click Find to begin your search. Figure 25.10 shows the results of a search for “chromium,” while looking for the Google open-source browser. Notice that any project with the name you are seeking is returned.
When you click to select, a subdirectory for the project is created in your Projects directory. Clicking it enables you to either fix bugs or fetch the Bazaar branch containing the source code for the part of the project that interests you, or all of it if it is a small project (see Figures 25.11 and 25.12). A branch is a version of the code or other items available, such as graphics or documentation.

Suppose you want the main development focus branch, which is the first one listed. However, if you were working with someone on a specific part of the code or something else like icons, you could find and download that branch. Select the branch, give it a local branch name in the bottom right, and click OK. Choose a unique name so that when you upload it later with your modifications, it won’t conflict with anything that currently exists. You will need to enter your ssh key password, which you created when you created your ssh key, to confirm your identity so that activity on this code can be traced. This
helps prevent, or at least track, sinister activity by people wanting to cause trouble, and it helps track or remove uploaded mistakes. It will find any and all revisions and download the code to your computer. You will now find files on your computer.

That should be enough to get you started. Committing your changes works similarly to submitting bug fixes. Ground Control is rather new and in active development that seems to go in spurts, with flurries of activity separated by months of inactivity, which is normal for a small team running a project on the side. For the latest on features and use instructions, check out the Ground Control website, listed in the Reference section.

There are many ways to help the Ubuntu community create, refine, and promote the operating system. Some are highly technical, like writing code or packaging programs to be included in the software repositories. Some are less technical, such as helping promote Ubuntu locally or through blogging interesting news items from the community. Somewhere in the middle, leaning toward the technical side, is a task that is wide open for greater community involvement.

This will be a rather brief and intentionally vague chapter. Testing by volunteers is something that requires more than a casual interest if it is going to be helpful to the developers and not an annoyance. For that reason, this chapter covers the basics of how to get involved and some of the opportunities, but not the precise details. If you are interested, and after reading this chapter we hope you are, the next step is to visit the websites listed at the end of the chapter.

Community Teams

There are two community teams that would love to see volunteers who can follow directions, be careful and methodical, and who notice details. Both teams work to refine the distribution during the development cycle to help make Ubuntu the best it can be.

The Ubuntu Testing Team works to collaborate the testing of release ISOs. An ISO is a one-file package that contains everything that goes on either a CD or a DVD, in our case the ISO contains everything needed to make Ubuntu install media. People in this team download install ISO files and
use precise methods to try to find any bugs in the installation process. The goal is to ensure that the ISOs released by Ubuntu will boot on as many computer hardware configurations as possible and will work properly. They also perform other tests, as explained next.

The Ubuntu QA Team looks directly at the overall quality of the distribution, trying out default programs and configurations and trying to break things. The goal is to find bugs during the development cycle and make clear reports about them, trying to get them fixed before end users ever know of their existence. The goal here is product improvement and quality control or assurance.

These are big tasks. Even with several Canonical employees working on these full time, it is nearly impossible to test every hardware configuration or use case. It is also impossible to guess what creative ways users will attempt to perform tasks that developers have designed to perform differently. Testing as many of these options as possible is key when the goal is to create a positive experience for as many people as possible. This is why volunteers are both welcome and actively recruited.

These are also exacting tasks. Testing and bug reporting (or fixing) requires careful attention so that problems are reported clearly with steps that can be repeated by developers. This enables them to find where problems lie and more easily fix them. Not everyone is well suited for this sort of thing, but those who are able to be clear and precise and who can follow the directions given in testing plans and procedures are worth their weight in gold. You may not receive public glory for testing, but you will receive honor from those working with you in testing if you are able to do the job well.

You will notice some crossover in the team descriptions that follow. That is because the teams work together closely. Although each has a main focus, each may perform similar tasks from time to time. Even the individual team’s web pages link to the others and offer similar information to help coordinate and direct any interested volunteers to the tasks they feel most equipped to help with.

**Ubuntu Testing Team**

Members of the Ubuntu Testing Team are probably best known for their work during a release week, when they help validate all of the CD and DVD images. They also operate during the release cycle testing beta releases and release candidates. In addition, they test update packages for stable releases before the packages are pushed out to users. They do this by enabling a new software repository called -proposed and trying out the software there before it ends up in the -updates repository. In addition, they help developers by coordinating communications and actively seeking and connecting additional volunteers when specific testing needs are encountered.

To get started, you need a Launchpad account. Then, join the Ubuntu Testing Team via the team’s page in Launchpad at https://launchpad.net/~ubuntu-testing. It is also a good idea to subscribe to the team’s email list at https://lists.ubuntu.com/mailman/listinfo/ubuntu-qa. When testers are needed, the Launchpad team list and the mailing list are the initial points of contact for those that are asked to help.
There are many ways to get involved in testing; each has varying requirements on time and technical skill. Some tasks are quick and easy, and others may be more involved. Some of the tests are general in nature, and others involve specific features, applications, and hardware. Some tests are automated and require specific test software to be downloaded and installed. Others are given as a list of instructions. Opportunities exist for many skill levels and most time schedules.

**QA Testing Team**

The QA Testing Team has a stronger focus on developing and using tools to automate the process. This enables people using the tools to run a large battery of tests against a code base very quickly while ensuring they are probing precisely what is needed. Much of their work is useful for hardware certification, logic testing, and bug discovery. They have developed an Ubuntu developer focused suite of tools called `ubuntu-qa-tools`, a library called Mago for the Linux Desktop Testing Project (LDTP) to simplify testing of Ubuntu within the wider realm of Linux desktops, and a framework called Checkbox that tests and sends test data directly to Launchpad.

**Bug Squad**

One of the first places people become involved in Ubuntu testing is with Bug Squad. These volunteers are the initial point of contact for most bugs filed with Ubuntu. They read bug reports to see if the bug seems legitimate (for example, that it isn’t something like “Ubuntu doesn’t work,” but is rather specific and measurable), that it is filed against the appropriate software package, and that adequate information is included with each report for the developers to be able to figure out the problem. If the bug report meets this criteria, the Bug Squad determines which developer or team should be notified. Sometimes during the triage process they may ask reporters for more information. They attempt to determine the severity of the bug and may assign a priority setting to the report.

**Test Drive**

One specific tool used by both volunteers and developers that deserves a mention is Test Drive. Dustin Kirkland is an Ubuntu developer on Canonical’s Ubuntu Server team. He was looking for an easy way to download and run the latest daily development snapshot of Ubuntu using a virtual machine like KVM or VirtualBox. Like any good developer who doesn’t want to repeat tasks unnecessarily, he wrote a tool to automate the process. While creating Test Drive, he made it configurable to use different virtual machines with different settings according to the user’s taste. It can even download and run any ISO that may be accessed via a URL, which means it could be used to download and run images from other distributions during their development cycles.

Test Drive is written in a way that enables even a nontechnical Ubuntu user to consistently test Ubuntu development releases. Test Drive is available in the Ubuntu repositories as `testdrive`. It runs from the command line, although a GUI front end is in active development and may be available by the time this book goes to print.
When you run the program, you are offered a menu:

```
matthew@seymour:~$ testdrive
```

Welcome to Testdrive!

1. Ubuntu Desktop (maverick-amd64)
2. Ubuntu Desktop (maverick-i386)
   +-cache—> [2010-07-20 00:08:09] maverick-desktop-i386.iso
3. Ubuntu Alternate (maverick-amd64)
4. Ubuntu Alternate (maverick-i386)
5. Ubuntu Netbook (maverick-i386)
6. Ubuntu Server (maverick-amd64)
7. Ubuntu Server (maverick-i386)
8. Other (prompt for ISO URL)

Select an image to testdrive [1]:

Type a number to download and run a specific ISO. As you can see, the preceding example is from the development cycle for Maverick Meercat, which eventually became Ubuntu 10.10.

The Test Drive configuration is stored in a simple text file and is easy to understand and edit (although many using Test Drive will never need to edit it). Test Drive will look several places for the testdriverc file, including the default location `/etc/testdriverc` as well as in the user's home directory at `/home/matthew/.testdriverc` and `/home/matthew/.config/testdrive/testdriverc`.

Here is an example:

```
# This is the global configuration file for the testdrive(1) utility.
[testdrive-common]

# CACHE is the directory to cache the ISOs and disk images
# Default: $HOME/.cache/testdrive
#CACHE = /path/to/your/cache

# CACHE_IMG and CACHE_ISO will default to $CACHE/img and $CACHE/iso, respectively. # You can set them explicitly if you want (specially interesting if you are # trying to run the image off /dev/shm. Make sure you have enough space there!!!
#CACHE_IMG = /dev/shm

# CLEAN_IMG will remove the just-generated image at the end of run. By default the image
# is kept, unless nothing was changed (i.e., the disk image was created, but no installation
# was actually tried).
```
# If running the image off /dev/shm, then *by default* the image will be removed
(memory is a
# restricted resource, and we should not over-allocate it)
#CLEAN_IMG = False

# VIRT is the type of hypervisor to use
# VIRT can be either 'kvm', 'virtualbox', or 'parallels'
VIRT = kvm
#VIRT = virtualbox
#VIRT = parallels

# MEM is the amount of memory in MB to give to the VM guest
# Default: 384
MEM = 384
#MEM = 512
#MEM = 1024

# SMP is the number of processors to give to the VM guest if
# running in KVM.
# Default is the number of CPUs in the host
#SMP = 1

# DISK_SIZE is the size of the disk image
# Note that this will be a sparse, qcow2 file, so it should not actually
# take that much space on the filesystem.
# Default: 6G
DISK_SIZE = 6G
#DISK_SIZE = 10G

# KVM_ARGS is a string of arbitrary KVM_ARGS to use when launching the VM
# See kvm(1) for a comprehensive list of arguments
KVM_ARGS = -usb -usbdevice tablet -net nic,model=virtio -net user -soundhw es1370 -
 vga vmware

# Uncomment the following line if you want to hardcode the Ubuntu release
# and arch; otherwise, TestDrive will try to determine it dynamically.
#r = maverick
#m = i386
u = rsync://cdimage.ubuntu.com/cdimage

# Section for TestDrive (Command-line) specific variables.
[testdrive]

# DISK_FILE is the full path to the disk image
# Default: $CACHE/$ISO.img
#DISK_FILE = /path/to/foo.img
# The following line determines the default Ubuntu Flavor used by TestDrive.
# Possible flavors are: ubuntu/kubuntu/xubuntu/edubuntu/mythbuntu/ubuntustudio
f = ubuntu

# Section for TestDrive GTK specific variables.
[testdrive-gtk]

# The following line determines the default Ubuntu Flavors used by TestDrive GTK.
# Possible flavors are: ubuntu/kubuntu/xubuntu/edubuntu/mythbuntu/ubuntustudio
f = ubuntu, kubuntu, xubuntu

Perl (the Practical Extraction and Report Language, or the Pathologically Eclectic Rubbish Lister, depending on who you speak to) is a powerful scripting tool that enables you to manage files, create reports, edit text, and perform many other tasks. Perl is included with and installed in Ubuntu by default and could be considered an integral part of the distribution because Ubuntu depends on Perl for many types of software services, logging activities, and software tools.

Perl is not the easiest of programming languages to learn because it is designed for flexibility. This chapter shows how to create and use Perl scripts on your system. You will see what a Perl program looks like, how the language is structured, and where you can find modules of prewritten code to help you write your own Perl scripts. This chapter also includes several examples of Perl used to perform a few common functions on a computer system.

Using Perl with Linux

Although originally designed as a data-extraction and report-generation language, Perl appeals to many Linux system administrators because it can be used to create utilities that fill a gap between the capabilities of shell scripts and compiled C programs. Another advantage of Perl over other UNIX tools is that it can process and extract data from binary files, whereas sed and awk cannot.
NOTE
In Perl, “there is more than one way to do it.” This is the unofficial motto of Perl, and it comes up so often that it is usually abbreviated as TIMTOWTDI.

You can use Perl at your shell’s command line to execute one-line Perl programs, but most often the programs (usually ending in `.pl`) are run as a command. These programs generally work on any computer platform because Perl has been ported to nearly every operating system.

Perl programs are used to support a number of Ubuntu services, such as system logging. For example, if you install the `logwatch` package, the `logwatch.pl` program is run every morning at 6:25 a.m. by the crond (scheduling) daemon on your system. Other Ubuntu services supported by Perl include the following:

- Amanda for local and network backups
- Fax spooling with the `faxrunqd` program
- Printing supported by Perl document filtering programs
- Hardware sensor monitoring setup using the `sensors-detect` Perl program

**Perl Versions**

As of this writing, the current production version of Perl from the Perl website is 5.12.1 (which is Perl Version 5 point 12, patch level 1). The version that was available at code freeze for the Ubuntu 10.10 release and that is available from the Ubuntu repositories is 5.10.1. Perl is installed from default.

You can download the code from www.perl.com and build the newest version from source if you want to, although a stable and quality release of Perl is already installed by default in Ubuntu and most (all?) Linux and Unix-like distributions, including Mac OS X. Updated versions may appear in the Ubuntu repositories, but generally only security fixes that can be installed by updating your system. See Chapter 32, “Managing Software,” to see how to quickly get a list of available updates for Ubuntu.

You can determine what version of Perl you installed by typing `perl -v` at a shell prompt. If you are installing the latest Ubuntu distribution, you should have the latest version of Perl that was available when the software for your Ubuntu release was gathered and finalized.

**A Simple Perl Program**

This section introduces a very simple sample Perl program to get you started using Perl. Although trivial for experienced Perl hackers, a short example is necessary for new users who want to learn more about Perl.

To introduce you to the absolute basics of Perl programming, Listing 27.1 illustrates a simple Perl program that prints a short message.
LISTING 27.1 A Simple Perl Program

#!/usr/bin/perl
print "Look at all the camels!\n";

Type that in and save it to a file called trivial.pl. Then make the file executable using the chmod command (see the following sidebar) and run it at the command prompt.

COMMAND-LINE ERROR

If you get the message bash: trivial.pl: command not found or bash: ./trivial.pl: Permission denied, you have either typed the command line incorrectly or forgotten to make trivial.pl executable (with the chmod command):

matthew@seymour:~$ chmod +x trivial.pl

You can force the command to execute in the current directory as follows:

matthew@seymour:~$ ./trivial.pl

Or you can use Perl to run the program like this:

matthew@seymour:~$ perl trivial.pl

The sample program in the listing is a two-line Perl program. Typing in the program and running it (using Perl or making the program executable) shows how to create your first Perl program, a process duplicated by Linux users around the world every day!

NOTE

#! is often pronounced she-bang, which is short for sharp (the musician's name for the # character), and bang, which is another name for the exclamation point. This notation is also used in shell scripts. See Chapter 11, “Automating Tasks,” for more information about writing shell scripts.

The #! line is technically not part of the Perl code at all. The # character indicates that the rest of the screen line is a comment. The comment is a message to the shell, telling it where it should go to find the executable to run this program. The interpreter ignores the comment line.

Exceptions to this practice include when the # character is in a quoted string and when it is being used as the delimiter in a regular expression. Comments are useful to document your scripts, like this:

#!/usr/bin/perl
# a simple example to print a greeting
print "hello there\n";

Download from www.eBookTM.com
A block of code, such as what might appear inside a loop or a branch of a conditional statement, is indicated with curly braces ({}). For example, here is an infinite loop:

```perl
#!/usr/bin/perl
# a block of code to print a greeting forever
while (1) {
    print "hello there\n";
};
```

Perl statements are terminated with a semicolon. A Perl statement can extend over several screen lines because Perl is not concerned about whitespace.

The second line of the simple program prints the text enclosed in quotation marks. \n is the escape sequence for a newline character.

---

**TIP**

Using the `perldoc` and `man` commands is an easy way to get more information about the version of Perl installed on your system. To learn how to use the `perldoc` command, enter the following:

```
matthew@seymour:~$ perldoc perldoc
```

To get introductory information on Perl, you can use either of these commands:

```
matthew@seymour:~$ perldoc perl
matthew@seymour:~$ man perl
```

For an overview or table of contents of Perl's documentation, use the `perldoc` command like this:

```
matthew@seymour:~$ perldoc perltoc
```

The documentation is extensive and well organized. Perl includes a number of standard Linux manual pages as brief guides to its capabilities, but perhaps the best way to learn more about Perl is to read its `perlfunc` document, which lists all the available Perl functions and their usage. You can view this document by using the `perldoc` script and typing `perldoc perlfunc` at the command line. You can also find this document online at http://perldoc.perl.org/.

---

**Perl Variables and Data Structures**

Perl is a *weakly typed* language, meaning that it does not require that you declare a data type, such as a type of value (data) to be stored in a particular variable. C, for example, makes you declare that a particular variable is an integer, a character, a structure, or whatever the case may be. Perl variables are whatever type they need to be, and can change type when you need them to.

**Perl Variable Types**

Perl has three variable types: *scalars, arrays, and hashes*. A different character is used to signify each variable type, so you can have the same name used with each type at the same time.
Scalar variables are indicated with the $ character, as in $penguin. Scalars can be numbers or strings, and they can change type from one to the other as needed. If you treat a number like a string, it becomes a string. If you treat a string like a number, it is translated into a number if it makes sense to do so; otherwise, it usually evaluates to 0. For example, the string “76trombones” evaluates as the number 76 if used in a numeric calculation, but the string “polar bear” evaluates to 0.

Perl arrays are indicated with the @ character, as in @fish. An array is a list of values referenced by index number, starting with the first element numbered 0, just as in C and awk. Each element in the array is a scalar value. Because scalar values are indicated with the $ character, a single element in an array is also indicated with a $ character.

For example, $fish[2] refers to the third element in the @fish array. This tends to throw some people off, but is similar to arrays in C in which the first array element is 0.

Hashes are indicated with the % character, as in %employee. A hash is a list of name and value pairs. Individual elements in the hash are referenced by name rather than by index (unlike an array). Again, because the values are scalars, the $ character is used for individual elements.

For example, $employee{name} gives you one value from the hash. Two rather useful functions for dealing with hashes are keys and values. The keys function returns an array containing all the keys of the hash, and values returns an array of the values of the hash. Using this approach, the Perl program in Listing 27.2 displays all the values in your environment, much like typing the bash shell’s env command.

LISTING 27.2 Displaying the Contents of the env Hash

```perl
#!/usr/bin/perl
foreach $key (keys %ENV)  {
    print "$key = $ENV{$key}\n";
}
```

Special Variables

Perl has a variety of special variables, which usually look like punctuation—$_, $!, and $]—and are all extremely useful for shorthand code. $_ is the default variable, $! is the error message returned by the operating system, and $] is the Perl version number.

$_ is perhaps the most useful of these. You will see that variable used often in this chapter. $_ is the Perl default variable, which is used when no argument is specified. For example, the following two statements are equivalent:

chomp;
chomp($_);
The following loops are equivalent:

```perl
for $cow (@cattle) {
    print "$cow says moo.
";
}
for (@cattle) {
    print "$_ says moo.
";
}
```

For a complete listing of the special variables, you should see the `perlvar` document that comes with your Perl distribution (such as in the `perlvar` manual page).

## Operators

Perl supports a number of operators to perform various operations. There are comparison operators (used to compare values, as the name implies), compound operators (used to combine operations or multiple comparisons), arithmetic operators (to perform math), and special string constants.

### Comparison Operators

The comparison operators used by Perl are similar to those used by C, `awk`, and the `csh` shells, and are used to specify and compare values (including strings). Most frequently, a comparison operator is used within an `if` statement or loop. Perl has comparison operators for numbers and strings. Table 27.1 shows the numeric comparison operators and their behavior.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>==</code></td>
<td>Is equal to</td>
</tr>
<tr>
<td><code>&lt;</code></td>
<td>Less than</td>
</tr>
<tr>
<td><code>&gt;</code></td>
<td>Greater than</td>
</tr>
<tr>
<td><code>&lt;=</code></td>
<td>Less than or equal to</td>
</tr>
<tr>
<td><code>&gt;=</code></td>
<td>Greater than or equal to</td>
</tr>
<tr>
<td><code>&lt;=&gt;</code></td>
<td>Returns –1 if less than, 0 if equal, and 1 if greater than</td>
</tr>
<tr>
<td><code>!=</code></td>
<td>Not equal to</td>
</tr>
<tr>
<td><code>..</code></td>
<td>Range of <code>&gt;=</code> first operand to <code>&lt;=</code> second operand</td>
</tr>
</tbody>
</table>
Table 27.2 shows the string comparison operators and their behaviors.

### TABLE 27.2  String Comparison Operators in Perl

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>eq</td>
<td>Is equal to</td>
</tr>
<tr>
<td>lt</td>
<td>Less than</td>
</tr>
<tr>
<td>gt</td>
<td>Greater than</td>
</tr>
<tr>
<td>le</td>
<td>Less than or equal to</td>
</tr>
<tr>
<td>ge</td>
<td>Greater than or equal to</td>
</tr>
<tr>
<td>ne</td>
<td>Not equal to</td>
</tr>
<tr>
<td>cmp</td>
<td>Returns -1 if less than, 0 if equal, and 1 if greater than</td>
</tr>
<tr>
<td>=~</td>
<td>Matched by regular expression</td>
</tr>
<tr>
<td>!~</td>
<td>Not matched by regular expression</td>
</tr>
</tbody>
</table>

**Compound Operators**

Perl uses compound operators, similar to those used by C or awk, which can be used to combine other operations (such as comparisons or arithmetic) into more complex forms of logic. Table 27.3 shows the compound pattern operators and their behavior.

### TABLE 27.3  Compound Pattern Operators in Perl

<table>
<thead>

</tr>
</tbody>
</table>

**Arithmetic Operators**

Perl supports a variety of math operations. Table 27.4 summarizes these operators.
You can also use comparison operators (such as == or <) and compound pattern operators (&&, ||, and !) in arithmetic statements. They evaluate to the value 0 for false and 1 for true.

**Other Operators**

Perl supports a number of operators that don’t fit any of the prior categories. Table 27.5 summarizes these operators.

### TABLE 27.5 Other Perl Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>~x</td>
<td>Bitwise not (changes 0 bits to 1 and 1 bits to 0)</td>
</tr>
<tr>
<td>x &amp; y</td>
<td>Bitwise and</td>
</tr>
<tr>
<td>x</td>
<td>y</td>
</tr>
<tr>
<td>x ^ y</td>
<td>Bitwise exclusive or (XOR)</td>
</tr>
<tr>
<td>x &lt;&lt; y</td>
<td>Bitwise shift left (shifts x by y bits)</td>
</tr>
<tr>
<td>x &gt;&gt; y</td>
<td>Bitwise shift right (shifts x by y bits)</td>
</tr>
<tr>
<td>x . y</td>
<td>Concatenate y onto x</td>
</tr>
<tr>
<td>a x b</td>
<td>Repeats string a for b number of times</td>
</tr>
</tbody>
</table>
Conditional Statements: if/else and unless

Except for the comma operator and conditional expression, these operators can also be used with the assignment operator, similar to the way addition (+) can be combined with assignment (=), giving +=.

Special String Constants

Perl supports string constants that have special meaning or cannot be entered from the keyboard.

Table 27.6 shows most of the constants supported by Perl.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Meaning</th>
</tr>
</thead>
</table>
| \
\ | The means of including a backslash |
| \a | The alert or bell character |
| \b | Backspace |
| \cC | Control character (like holding the Ctrl key down and pressing the C character) |
| \e | Escape |
| \f | Formfeed |
| \n | Newline |
| \r | Carriage return |
| \t | Tab |
| \xNN | Indicates that NN is a hexadecimal number |
| \0NNN | Indicates that NNN is an octal (base 8) number |

Conditional Statements: if/else and unless

Perl offers two conditional statements, if and unless, which function opposite one another. if enables you to execute a block of code only if certain conditions are met so that you can control the flow of logic through your program. Conversely, unless performs the statements when certain conditions are not met.
The following sections explain and demonstrate how to use these conditional statements when writing scripts for Linux.

**if**

The syntax of the Perl `if/else` structure is as follows:

```perl
if (condition) {
    statement or block of code
} elsif (condition) {
    statement or block of code
} else {
    statement or block of code
}
```

*condition* is a statement that returns a true or false value.

Truth is defined in Perl in a way that might be unfamiliar to you, so be careful. Everything in Perl is true except 0 (the digit zero), "0" (the string containing the number 0), "" (the empty string), and an undefined value. Note that even the string "00" is a true value because it is not one of the four false cases.

The statement or block of code is executed if the test condition returns a true value.

For example, Listing 27.3 uses the `if/else` structure and shows conditional statements using the `eq` string comparison operator.

**LISTING 27.3 if/elsif/else**

```perl
if ($favorite eq "chocolate") {
    print "I like chocolate too.\n";
} elsif ($favorite eq "spinach") {
    print "Oh, I don't like spinach.\n";
} else {
    print "Your favorite food is $favorite.\n";
}
```

**unless**

`unless` works just like `if`, only backward. `unless` performs a statement or block if a condition is false:

```perl
unless ($name eq "Rich") {
    print "Go away, you're not allowed in here!\n";
}
```
Looping

A loop is a way to repeat a program action multiple times. A very simple example is a countdown timer that performs a task (waiting for one second) 300 times before telling you that your egg is done boiling.

Looping constructs (also known as control structures) can be used to iterate a block of code as long as certain conditions apply, or while the code steps through (evaluates) a list of values, perhaps using that list as arguments.

Perl has four looping constructs: for, foreach, while, and until.

for

The for construct performs a statement (block of code) for a set of conditions defined as follows:

for (start condition; end condition; increment function) {
    statement(s)
}

The start condition is set at the beginning of the loop. Each time the loop is executed, the increment function is performed until the end condition is achieved. This looks much like the traditional for/next loop. The following code is an example of a for loop:

```perl
for ($i=1; $i<=10; $i++) {
    print "$i\n"
}
```

foreach

The foreach construct performs a statement block for each element in a list or array:

```perl
@names = ("alpha","bravo","charlie");
foreach $name (@names) {
    print "$name sounding off!\n"
}
```
The loop variable ($name in the example) is not merely set to the value of the array elements; it is aliased to that element. That means if you modify the loop variable, you’re actually modifying the array. If no loop array is specified, the Perl default variable $_ may be used:

```perl
@names = ("alpha","bravo","charlie");
foreach (@names) {
    print "$_ sounding off!\n";
}
```

This syntax can be very convenient, but it can also lead to unreadable code. Give a thought to the poor person who’ll be maintaining your code. (It will probably be you.)

**NOTE**

`foreach` is frequently abbreviated as `for`.

### while

while performs a block of statements as long as a particular condition is true:

```perl
while ($x<10) {
    print "$x\n";
    $x++;
}
```

Remember that the condition can be anything that returns a true or false value. For example, it could be a function call:

```perl
while ( InvalidPassword($user, $password) ) {
    print "You've entered an invalid password. Please try again.\n";
    $password = GetPassword;
}
```

### until

until is the exact opposite of the while statement. It performs a block of statements as long as a particular condition is false—or, rather, until it becomes true:

```perl
until (ValidPassword($user, $password)) {
    print "YSdpgm_m
Sdpgm_m
You have entered an invalid password. Please try again.\n";
    $password = GetPassword;
}
```
**last and next**

You can force Perl to end a loop early by using a `last` statement. `last` is similar to the C `break` command—the loop is exited. If you decide you need to skip the remaining contents of a loop without ending the loop itself, you can use `next`, which is similar to the C `continue` command. Unfortunately, these statements don’t work with `do ... while`.

On the other hand, you can use `redo` to jump to a loop (marked by a label) or inside the loop where called:

```perl
$a = 100;
while (1) {
    print "start\n";
    TEST: {
        if ($a = $a / 2) > 2) {
            print "$a\n";
            if (−$a < 2) {
                exit;
            }
        redo TEST;
    }
}
```

In this simple example, the variable `$a` is repeatedly manipulated and tested in an endless loop. The word `start` will be printed only once.

**do ... while and do ... until**

The `while` and `until` loops evaluate the conditional first. The behavior is changed by applying a `do` block before the conditional. With the `do` block, the condition is evaluated last, which results in the contents of the block always executing at least once (even if the condition is false). This is similar to the C language `do ... while (conditional)` statement.

**Regular Expressions**

Perl’s greatest strength is in text and file manipulation, which is accomplished by using the regular expression (regex) library. Regexes, which are quite different from the wildcard-handling and filename-expansion capabilities of the shell (see Chapter 15), allow complicated pattern matching and replacement to be done efficiently and easily.

For example, the following line of code replaces every occurrence of the string `bob` or the string `mary` with `fred` in a line of text:

```perl
$string =~ s/bob|mary/fred/gi;
```

Without going into too many of the details, Table 27.7 explains what the preceding line says.
If you are interested in the details, you can get more information using the regex (7) section of the manual.

Although replacing one string with another might seem a rather trivial task, the code required to do the same thing in another language (for example, C) is rather daunting unless supported by additional subroutines from external libraries.

### Access to the Shell

Perl can perform for you any process you might ordinarily perform by typing commands to the shell through the `\` syntax. For example, the code in Listing 27.4 prints a directory listing.

#### LISTING 27.4 Using Backticks to Access the Shell

```perl
$curr_dir = 'pwd';
@listing = 'ls -al';
print "Listing for $curr_dir\n";
foreach $file (@listing) {
    print "$file";
}
```

<table>
<thead>
<tr>
<th>Element</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>$string =~ s/bob</td>
<td>mary/fred/gi;</td>
</tr>
<tr>
<td>s</td>
<td>Substitute.</td>
</tr>
<tr>
<td>/</td>
<td>Begins the text to be matched.</td>
</tr>
<tr>
<td>bob</td>
<td>mary</td>
</tr>
<tr>
<td>fred</td>
<td>Replaces anything that was matched with the text fred.</td>
</tr>
<tr>
<td>/</td>
<td>Ends replace text.</td>
</tr>
<tr>
<td>g</td>
<td>Does this substitution globally; that is, replaces the match text wherever in the string you match it (and any number of times).</td>
</tr>
<tr>
<td>i</td>
<td>The search text is not case sensitive. It matches bob, Bob, or bOB.</td>
</tr>
<tr>
<td>;</td>
<td>Indicates the end of the line of code.</td>
</tr>
</tbody>
</table>
NOTE

The `\` notation uses the backtick found above the Tab key (on most keyboards), not the single quotation mark.

You can also use the Shell module to access the shell. Shell is one of the standard modules that comes with Perl; it allows creation and use of a shell-like command line. Look at the following code for an example:

```perl
use Shell qw(cp);
cp ('/home/httpd/logs/access.log', '/tmp/httpd.log');
```

This code almost looks like it is importing the command-line functions directly into Perl. Although that is not really happening, you can pretend that the code is similar to a command line and use this approach in your Perl programs.

A third method of accessing the shell is via the system function call:

```perl
$rc = 0xffff & system('cp /home/httpd/logs/access.log /tmp/httpd.log');
if ($rc == 0) {
    print "system cp succeeded \n";
} else {
    print "system cp failed $rc\n";
}
```

The call can also be used with the or die clause:

```perl
system('cp /home/httpd/logs/access.log /tmp/httpd.log') == 0
    or die "system cp failed: $?"
```

However, you can’t capture the output of a command executed through the system function.

**Modules and CPAN**

A great strength of the Perl community (and the Linux community) is the fact that it is an open-source community. This community support is expressed for Perl via the Comprehensive Perl Archive Network (CPAN), which is a network of mirrors of a repository of Perl code.

Most of CPAN is made up of modules, which are reusable chunks of code that do useful things, similar to software libraries containing functions for C programmers. These
modules help speed development when building Perl programs and free Perl hackers from repeatedly reinventing the wheel when building a bicycle.

Perl comes with a set of standard modules installed. Those modules should contain much of the functionality that you will initially need with Perl. If you need to use a module not installed with Ubuntu, use the CPAN module (which is one of the standard modules) to download and install other modules onto your system. At www.perl.com/CPAN, you will find the CPAN Multiplex Dispatcher, which will attempt to direct you to the CPAN site closest to you.

Typing the following command will put you into an interactive shell that gives you access to CPAN. You can type help at the prompt to get more information on how to use the CPAN program:

```bash
$ perl -MCPAN -e shell
```

After installing a module from CPAN (or writing one of your own), you can load that module into memory where you can use it with the `use` function:

```perl
use Time::CTime;
```

`use` looks in the directories listed in the variable `@INC` for the module. In this example, `use` looks for a directory called `Time`, which contains a file called `CTime.pm`, which in turn is assumed to contain a package called `Time::CTime`. The distribution of each module should contain documentation on using that module.

For a list of all the standard Perl modules (those that come with Perl when you install it), see `perlmodlib` in the Perl documentation. You can read this document by typing `perldoc perlmodlib` at the command prompt.

## Code Examples

The following sections contain a few examples of things you might want to do with Perl.

### Sending Mail

You can get Perl to send email in several ways. One method that you see frequently is opening a pipe to the `sendmail` command and sending data to it (shown in Listing 27.5). Another method is using the `Mail::Sendmail` module (available through CPAN), which uses socket connections directly to send mail (as shown in Listing 27.6). The latter method is faster because it does not have to launch an external process. Note that `sendmail` must be running on your system for the Perl program in Listing 27.5 to work.

**LISTING 27.5  Sending Mail Using Sendmail**

```bash
#!/usr/bin/perl
open (MAIL, "| /usr/sbin/sendmail -t"); # Use -t to protect from users
print MAIL <<EndMail;
```

Download from www.eBookTM.com
To: you
From: me
Subject: A Sample Email
Sending email from Perl is easy!

EndMail
close MAIL;

NOTE

The @ sign in the email addresses must be escaped so that Perl does not try to evaluate an array of that name. That is, dpitts@mk.net will cause a problem, so you need to use dpitts\<indexterm startref="iddle2799" class="endofrange" significance="normal"/>

The syntax used to print the mail message is called a here document. The syntax is as follows:

```perl
print <<EndText;
.....
EndText
```

The EndText value must be identical at the beginning and at the end of the block, including any whitespace.

LISTING 27.6 Sending Mail Using the Mail::Sendmail Module

```perl
#!/usr/bin/perl
use Mail::Sendmail;

%mail = ( To => 'you@there.com',
          From => 'me@here.com',
          Subject => 'A Sample Email',
          Message => "This is a very short message"
);

sendmail(%mail) or die $Mail::Sendmail::error;

print "OK. Log says:
", $Mail::Sendmail::log;

use Mail::Sendmail;
```

Perl ignores the comma after the last element in the hash. It is convenient to leave it there; if you want to add items to the hash, you don’t need to add the comma. This is purely a style decision.
USING PERL TO INSTALL A CPAN MODULE

You can use Perl to interactively download and install a Perl module from the CPAN archives by using the `-M` and `-e` commands. Start the process by using a Perl like this:

```
# perl -MCPAN -e shell
```

After you press Enter, you will see some introductory information and be asked to choose an initial automatic or manual configuration, which is required before any download or install takes place. Type `no` and press Enter to have Perl automatically configure for the download and install process; or, if desired, simply press Enter to manually configure for downloading and installation. If you use manual configuration, you must answer a series of questions regarding paths, caching, terminal settings, program locations, and so on. Settings are saved in a directory named `.cpan` in current directory.

When finished, you will see the CPAN prompt:

```
cpan>
```

To have Perl examine your system and then download and install a large number of modules, use the `install` keyword, specify `Bundle` at the prompt, and then press Enter, like this:

```
cpan> install Bundle::CPAN
```

To download a desired module (using the example in Listing 27.6), use the `get` keyword like this:

```
cpan> get Mail::Sendmail
```

The source for the module will be downloaded into the `.cpan` directory. You can then build and install the module using the `install` keyword, like this:

```
cpan> install Mail::Sendmail
```

The entire process of retrieving, building, and installing a module can also be accomplished at the command line by using Perl’s `-e` option, like this:

```
# perl -MCPAN -e "install Mail::Sendmail"
```

Note also that the `@` sign did not need to be escaped within single quotation marks (`'`). Perl does not `interpolate` (evaluate variables) within single quotation marks, but does within double quotation marks and here strings (similar to `<<` shell operations).

Purging Logs

Many programs maintain some variety of logs. Often, much of the information in the logs is redundant or just useless. The program shown in Listing 27.7 removes all lines from a file that contain a particular word or phrase, so lines that you know are not important can be purged. For example, you might want to remove all the lines in the Apache error log that originate with your test client machine because you know those error messages were produced during testing.
LISTING 27.7 Purging Log Files

#!/usr/bin/perl
# Be careful using this program!
# This will remove all lines that contain a given word
# Usage: remove <word> <file>
$word=@ARGV[0];
$file=@ARGV[1];
if ($file) {
    # Open file for reading
    open (FILE, "$file") or die "Could not open file: $!";  @lines=<FILE>;
    close FILE;
    # Open file for writing
    open (FILE, ">$file") or die "Could not open file for writing: $!";
    for (@lines) {
        print FILE unless /$word/;
    }  # End for
    close FILE;
} else {
    print "Usage: remove <word> <file>\n";
}  #  End if...else

The code uses a few idiomatic Perl expressions to keep it brief. It reads the file into an array using the <FILE> notation; it then writes the lines back out to the file unless they match the pattern given on the command line.

The die function kills program operation and displays an error message if the open statements fail. $! in the error message, as mentioned in the section on special variables, is the error message returned by the operating system. It will likely be something like 'file not found' or 'permission denied'.

Posting to Usenet

If some portion of your job requires periodic postings to Usenet—a FAQ listing, for example—the following Perl program can automate the process for you. In the sample code, the posted text is read in from a text file, but your input can come from anywhere.

The program shown in Listing 27.8 uses the Net::NNTP module, which is a standard part of the Perl distribution. You can find more documentation on the Net::NNTP module by typing 'perldoc Net::NNTP' at the command line.

LISTING 27.8 Posting an Article to Usenet

#!/usr/bin/perl
# load the post data into @post
open (POST, "post.file");
@post = <POST>;

close POST;
# import the NNTP module
use Net::NNTP;
$NNTPhost = 'news';
# attempt to connect to the remote host;
# print an error message on failure
$nntp = Net::NNTP->new($NNTPhost)
or die "Cannot contact $NNTPhost: $!";
# $nntp->debug(1);
$nntp->post()
or die "Could not post article: $!";
# send the header of the post
$nntp->datasend("Newsgroups: news.announce\n");
$nntp->datasend("Subject: FAQ - Frequently Asked Questions\n");
$nntp->datasend("From: ADMIN <root\n");
$nntp->datasend("\n\n");
# for each line in the @post array, send it
for (@post) {
    $nntp->datasend($_);
} # End for
$nntp->quit;

One-Liners

One medium in which Perl excels is the one-liner. Folks go to great lengths to reduce tasks to one line of Perl code. Perl has the rather undeserved reputation of being unreadable. The fact is that you can write unreadable code in any language. Perl allows for more than one way to do something, and this leads rather naturally to people trying to find the most arcane way to do things.

Named for Randal Schwartz, a Schwartzian Transform is a way of sorting an array by something that is not obvious. The sort function sorts arrays alphabetically; that is pretty obvious. What if you want to sort an array of strings alphabetically by the third word? Perhaps you want something more useful, such as sorting a list of files by file size? A Schwartzian Transform creates a new list that contains the information that you want to sort by, referencing the first list. You then sort the new list and use it to figure out the order that the first list should be in. Here's a simple example that sorts a list of strings by length:

```perl
@sorted_by_length =
    map { $_ => [0] }            # Extract original list
    sort { $a->[1] <=> $b->[1] } # Sort by the transformed value
    map { [$_, length($_)] }     # Map to a list of element lengths
@list;
```

Because each operator acts on the thing immediately to the right of it, it helps to read this from right to left (or bottom to top, the way it is written here).
The first thing that acts on the list is the `map` operator. It transforms the list into a hash in which the keys are the list elements and the values are the lengths of each element. This is where you put in your code that does the transformation by which you want to sort.

The next operator is the sort function, which sorts the list by the values.

Finally, the hash is transformed back into an array by extracting its keys. The array is now in the desired order.

**Command-Line Processing**

Perl is great at parsing the output of various programs. This is a task for which many people use tools such as `awk` and `sed`. Perl gives you a larger vocabulary for performing these tasks. The following example is very simple, but illustrates how you might use Perl to chop up some output and do something with it. In the example, Perl is used to list only those files that are larger than 10KB:

```
```

The `-n` switch indicates that I want the Perl code run for each line of the output. The `-a` switch automatically splits the output into the `@F` array. The `-e` switch indicates that the Perl code is going to follow on the command line.

**RELATED UBUNTU AND LINUX COMMANDS**

You will use these commands and tools when using Perl with Linux:

- `a2p`—A filter used to translate awk scripts into Perl
- `find2perl`—A utility used to create Perl code from command lines using the `find` command
- `perldoc`—A Perl utility used to read Perl documentation
- `s2p`—A filter used to translate sed scripts into Perl
- `vi`—The vi (actually Vim) text editor

**Reference**

The first place to look is in the Perl documentation and Linux man pages.

Perl, all of its documentation, and millions of lines of Perl programs are all available free on the Internet. A number of Usenet newsgroups are also devoted to Perl, as are shelves of books and a quarterly journal.

**Books**

Although your local bookstore might have dozens of titles on Perl, the following are some of the more highly recommended of these. You might also look at the *Camel Critiques* (Tom Christiansen; http://language.perl.com/critiques/index.html) for reviews of other available Perl books.
Advanced Perl Programming, by Sriram Srinivasan, O’Reilly & Associates

Sams Teach Yourself Perl in 24 Hours, Second Edition, by Clinton Pierce, Sams Publishing

Programming Perl, third edition, by Larry Wall, Tom Christiansen, and Jon Orwant, O’Reilly & Associates

Effective Perl Programming: Writing Better Programs with Perl, by Joseph Hall, Addison-Wesley Publishing Company

Mastering Regular Expressions, by Jeffrey Friedl, O’Reilly & Associates

Usenet

Check out the following on Usenet:

comp.lang.perl.misc—Discusses various aspects of the Perl programming language. Make sure that your questions are Perl specific, not generic CGI programming questions. The regulars tend to flame folks who don’t know the difference.

comp.infosystems.www.authoring.cgi—Discusses authoring of CGI programs, so much of the discussion is Perl specific. Make sure that your questions are related to CGI programming, not just Perl. The regulars are very particular about staying on topic.

Websites

Check these sites on the World Wide Web:

http://www.perl.com—Tom Christiansen maintains the Perl language home page. This is the place to find all sorts of information about Perl, from its history and culture to helpful tips. This is also the place to download the Perl interpreter for your system.

http://cpan.perl.org—CPAN (Comprehensive Perl Archive Network) is the place for you to find modules and programs in Perl. If you write something in Perl that you think is particularly useful, you can make it available to the Perl community here.

http://perldoc.perl.org/index-faq.html—Frequently Asked Questions index of common Perl queries; this site offers a handy way to quickly search for answers about Perl.

http://learn.perl.org—One of the best places to start learning Perl online. If you master Perl, go to http://jobs.perl.org.

www.pm.org—The Perl Mongers are local Perl users groups. There might be one in your area. The Perl advocacy site is http://www.perl.org.

**Other**

Other valuable resources not falling into any of the preceding categories are Perl-related Internet Relay Chat channels. You can usually find several channels available on an IRC server. However, the questions, discussions, and focus of similarly named channels will vary from server to server.

For example, a #perlhelp channel is usually for general questions about installing, using, and learning about Perl. A #perl channel is generally for more advanced questions, but on some servers beginner questions might be welcomed. You might also find some helpful answers on #cgi and #html channels. Browse to http://perl-begin.berlios.de/irc for a list of servers.
As PHP has come to dominate the world of web scripting, Python is increasingly dominating the domain of command-line scripting. Python's precise and clean syntax makes it one of the easiest languages to learn, and it allows programmers to code more quickly and spend less time maintaining their code. Although PHP is fundamentally similar to Java and Perl, Python is closer to C and Modula-3, and so it might look unfamiliar at first.

Most of the other languages have a group of developers at their cores, but Python has Guido van Rossum—creator, father, and Benevolent Dictator for Life (BDFL). Although Guido spends less time working on Python now, he still essentially has the right to veto changes to the language, which has enabled it to remain consistent over the many years of its development. The end result is that, in Guido's own words, “Even if you are in fact clueless about language design, you can tell that Python is a very simple language.”

This chapter constitutes a “quick-start” tutorial to Python designed to give you all the information you need to put together basic scripts and to point you toward resources that can take you further.

Two supported version of Python are out in the wild right now. Python Version 2.x (the current production release is 2.7) is the backward-compatible status quo, the version that anyone who has already used Python for more than a year or two has learned and the version most likely to have been used in already written code you discover and read. Python 3.x is the newest branch (the current production release is 3.1.2) with lots of shiny newness.
Python 3.x is not backward compatible, and most programs written in or for 2.x will need some work to run on 3.x. This should be a factor in any decision you make about using Python: Do you want to run your program on many machines, perhaps including some that have only the older version installed? Does the newer version have all the functionality you want and need, including software libraries, because not all of them have been rewritten for 3.x (like Twisted and Django)? If porting is a nontrivial task, you may want to stick with 2.x for now.

Both versions will be supported for some time, but if you expect you will be using what you write for a very long time, you probably want to try to do so in 3.x, but with a readiness to fall back to 2.x if you discover significant blocking limitations currently in 3.x. The language itself is ready for use, though, and is receiving high marks from people who have used both versions. The official Python website will help you make an informed decision; it contains clear discussion of the advantages and disadvantages of each version at http://wiki.python.org/moin/Python2orPython3.

This chapter is centered on the 2.x version of Python because it is what most people are still using in late 2010 when this was written, but we will try to note places where significant differences exist in 3.x that should be considered. If you are learning Python for the first time, you may want to start with a look at the 3.x series because it is the future and is very likely to already have everything you need. Ubuntu 10.10 comes with Python 2.6.6 installed by default with 2.7 available in the repositories, which is another reason for us to focus this chapter on the 2.x series (although the current 3.x is also available in the repositories and available for easy installation).

NOTE

This chapter is a very elementary introduction to Python. For that reason, nearly everything we cover is identical in both 2.x and 3.x. We mention the differences earlier and in a couple of notes that follow so that readers wanting to learn more will not be surprised later. Unless noted otherwise, you should find what we say in this chapter applies well to either version.

Python on Linux

Most versions of Linux and UNIX, including Mac OS X, come with Python preinstalled. This is partially for convenience because it is such a popular scripting language—and it saves having to install it later if the user wants to run a script—and partially because many vital or useful programs included in Linux distributions are written in Python. For example, the Ubuntu Software Center is a Python program.

The Python binary is installed into /usr/bin/python (or /usr/bin/python3); if you run that, you enter the Python interactive interpreter where you can type commands and have them executed immediately. Although PHP also has an interactive mode (use php -a to activate it), it is neither as powerful nor as flexible as Python’s.
As with Perl, PHP, and other scripting languages, you can also execute Python scripts by adding a shebang line (#!) to the start of your scripts that point to /usr/bin/python and then setting the file to be executable.

The third way to run Python scripts is through mod_python, which is an Apache module that embeds the Python interpreter into the http server, allowing you to use Python to write web applications. You can install from the Ubuntu repositories.

For the purposes of this introduction, we use the interactive Python interpreter because it provides immediate feedback on commands as you type them.

We will be using the interactive interpreter for this chapter, so it is essential that you become comfortable using it. To get started, open a terminal and run the command python. You should see something like this, perhaps with different version numbers and dates:

```
matthew@seymour:~$ python
Python 2.6.6rc2 (r266rc2:84114, Aug 18 2010, 09:46:34)
[GCC 4.4.5 20100816 (prerelease)] on linux2
Type "help", "copyright", "credits" or "license" for more information.

>>> 
```

The >>> is where you type your input, and you can set and get a variable like this:

```
>>> python = 'great'
>>> python
'great'
```

On line one, the variable python is set to the text great, and on line two that value is read back from the variable simply by typing the name of the variable you want to read. Line three shows Python printing the variable; on line four you are back at the prompt to type more commands. Python remembers all the variables you use while in the interactive interpreter, which means you can set a variable to be the value of another variable.

When you are done, press Ctrl+D to exit. At this point, all your variables and commands are forgotten by the interpreter, which is why complex Python programs are always saved in scripts!

---

**The Basics of Python**

Python is a language wholly unlike most others, and yet it is so logical that most people can pick it up quickly. You have already seen how easily you can assign strings, but in Python nearly everything is that easy—as long as you remember the syntax.

**Numbers**

The way Python handles numbers is more precise than some other languages. It has all the normal operators—such as + for addition, - for subtraction, / for division, and * for multiplication—but it adds % for modulus (division remainder), ** for raise to the power,
and // for floor division. It is also specific about which type of number is being used, as this example shows:

```python
>>> a = 5
>>> b = 10
>>> a * b
50
>>> a / b
0
>>> b = 10.0
>>> a / b
0.5
>>> a // b
0.0
```

The first division returns 0 because both a and b are integers (whole numbers), so Python calculates the division as an integer, giving 0. By converting b to 10.0, Python considers it to be a floating-point number, and so the division is now calculated as a floating-point value, giving 0.5. Even with b being a floating point, using //—floor division—rounds it down.

Using **, you can easily see how Python works with integers:

```python
>>> 2 ** 30
1073741824
>>> 2 ** 31
2147483648L
```

The first statement raises 2 to the power of 30 (that is, 2... times 2 times 2 times 2...), and the second raises 2 to the power of 31. Notice how the second number has a capital L on the end of it—this is Python telling you that it is a long integer. The difference between long integers and normal integers is slight but important: Normal integers can be calculated using simple instructions on the CPU, whereas long integers—because they can be as big as you need them to be—need to be calculated in software and therefore are slower.

When specifying big numbers, you need not put the L at the end—Python figures it out for you. Furthermore, if a number starts off as a normal number and then exceeds its boundaries, Python automatically converts it to a long integer. The same is not true the other way around: If you have a long integer and then divide it by another number so that it could be stored as a normal integer, it remains a long integer:

```python
>>> num = 999999999999999999999999999999999L
>>> num = num / 1000000000000000000000000000000
>>> num
999L
```
You can convert between number types using typecasting, like this:

```python
>>> num = 10
>>> int(num)
10
>>> float(num)
10.0
>>> long(num)
10L
>>> floatnum = 10.0
>>> int(floatnum)
10
>>> float(floatnum)
10.0
>>> long(floatnum)
10L
```

You need not worry whether you are using integers or long integers; Python handles it all for you, so you can concentrate on getting the code right. In the 3.x series, the Python integer type automatically provides extra precision for large numbers, whereas in 2.x you would use a separate long integer type for numbers larger than the normal integer type is designed to handle.

**More on Strings**

Python stores strings as an immutable sequence of characters—a jargon-filled way of saying that “it is a collection of characters that, once set, cannot be changed without creating a new string.” Sequences are important in Python. There are three primary types, of which strings are one, and they share some properties. Mutability makes a lot of sense when you learn about lists in the next section.

As you saw in the previous example, you can assign a value to strings in Python with just an equal sign, like this:

```python
>>> mystring = 'hello';
>>> myotherstring = "goodbye";
>>> mystring
'hello'
>>> myotherstring;
'goodbye'
>>> test = "Are you really Bill O'Reilly?"
>>> test
"Are you really Bill O'Reilly?"
```

The first example encapsulates the string in single quotation marks, and the second and third in double quotation marks. However, printing the first and second strings shows
them both in single quotation marks because Python does not distinguish between the two. The third example is the exception—it uses double quotation marks because the string itself contains a single quotation mark. Here, Python prints the string with double quotation marks because it knows it contains the single quotation mark.

Because the characters in a string are stored in sequence, you can index into them by specifying the character you are interested in. Like most other languages, these indexes are zero based, which means you need to ask for character 0 to get the first letter in a string. For example:

```python
>>> string = "This is a test string"
>>> string
'This is a test string'
>>> string[0]
'T'
>>> string [0], string[3], string [20]
('T', 's', 'g')
```

The last line shows how, with commas, you can ask for several indexes at the same time. You could print the entire first word using this:

```python
>>> string[0], string[1], string[2], string[3]
('T', 'h', 'i', 's')
```

However, for that purpose you can use a different concept: slicing. A slice of a sequence draws a selection of indexes. For example, you can pull out the first word like this:

```python
>>> string[0:4]
'This'
```

The syntax there means “take everything from position 0 (including 0) and end at position 4 (excluding it).” So, [0:4] copies the items at indexes 0, 1, 2, and 3. You can omit either side of the indexes, and it will copy either from the start or to the end:

```python
>>> string [:4]
'This'
```

You can also omit both numbers, and it will give you the entire sequence:

```python
>>> string [:]
'This is a test string'
```
Later you will learn precisely why you would want to do that, but for now there are a number of other string intrinsics that will make your life easier. For example, you can use the + and * operators to concatenate (join) and repeat strings, like this:

```python
>>> mystring = "Python"
>>> mystring * 4
'PythonPythonPythonPython'
>>> mystring = mystring + " rocks! 
>>> mystring * 2
'Python rocks! Python rocks! '
```

In addition to working with operators, Python strings come with a selection of built-in methods. You can change the case of the letters with `capitalize()` (uppercases the first letter and lowercases the rest), `lower()` (lowercases them all), `title()` (uppercases the first letter in each word), and `upper()` (uppercases them all). You can also check whether strings match certain cases with `islower()`, `istitle()`, and `isupper()`; that also extends to `isalnum()` (returns true if the string is letters and numbers only) and `isdigit()` (returns true if the string is all numbers).

This example demonstrates some of these in action:

```python
>>> string
'This is a test string'
>>> string.upper()
'THIS IS A TEST STRING'
>>> string.lower()
'this is a test string'
>>> string.isalnum()
False
>>> string = string.title()
>>> string
'This Is A Test String'
```

Why did `isalnum()` return false—our string contains only alphanumeric characters, doesn't it? Well, no. There are spaces in there, which is what is causing the problem. More important, we were calling `upper()` and `lower()` and they were not changing the contents of the string—they just returned the new value. So, to change our string from `This is a test string` to `This Is A Test String`, we have to assign it back to the string variable.

Another really useful and kind of cool thing you can do with strings is triple quoting. This lets you easily create strings that include both double and single quoted strings, as well as strings that span more than one line, without having to escape a bunch of special characters. Here's an example:

```python
>>>foo = ""
```
..."foo"
...'bar'
...baz
...blippy
...

>>> foo
'\n"foo"\n'\n'bar'\n'\nbaz\nblippy\n'

Although this is intended as an introductory guide, the capability to use negative indexes with strings and slices is a pretty neat feature that deserves a mention. Here’s an example:

>>> bar="news.google.com"
>>> bar[-1]
'm'
>>> bar[-4:]
'.com'
>>> bar[-10:-4]
'google'

One difference between 2.x and 3.x is the introduction of new string types and method calls. That doesn’t affect what we share here, but is something to pay attention to as you work with Python.

Lists

Python’s built-in list data type is a sequence, like strings. However, they are mutable, which means they can be changed. Lists are like arrays in that they hold a selection of elements in a given order. You can cycle through them, index into them, and slice them:

>>> mylist = ["python", "perl", "php"]
>>> mylist
['python', 'perl', 'php']
>>> mylist + ["java"]
['python', 'perl', 'php', 'java']
>>> mylist * 2
['python', 'perl', 'php', 'python', 'perl', 'php']
>>> mylist[1]
'perl'
>>> mylist[1] = "c++"
>>> mylist[1]
'c++'
>>> mylist[1:3]
['c++', 'php']
The brackets notation is important: You cannot use parentheses, (( and )) or braces ( { and } ) for lists. Using + for lists is different from using + for numbers. Python detects you are working with a list and appends one list to another. This is known as operator overloading, and it is one of the reasons Python is so flexible.

Lists can be nested, which means you can put a list inside a list. However, this is where mutability starts to matter, and so this might sound complicated. If you recall, the definition of an immutable string sequence is that it is a collection of characters that, once set, cannot be changed without creating a new string. Lists are mutable, as opposed to immutable, which means you can change your list without creating a new list.

This becomes important because Python, by default, copies only a reference to a variable rather than the full variable. For example:

```python
>>> list1 = [1, 2, 3]
>>> list2 = [4, list1, 6]
>>> list1
[1, 2, 3]
>>> list2
[4, [1, 2, 3], 6]
```

Here we have a nested list. list2 contains 4, then list1, then 6. When you print the value of list2, you can see it also contains list1. Now, proceeding on from that:

```python
>>> list1[1] = "Flake"
>>> list2
[4, [1, 'Flake', 3], 6]
```

In line one, we set the second element in list1 (remember, sequences are zero based!) to be Flake rather than 2; then we print the contents of list2. As you can see, when list1 changed, list2 was updated, too. The reason for this is that list2 stores a reference to list1 as opposed to a copy of list1; they share the same value.

We can show that this works both ways by indexing twice into list2, like this:

```python
>>> list2[1][1] = "Caramello"
>>> list1
[1, 'Caramello', 3]
```

The first line says, “Get the second element in list2 (list1) and the second element of that list, and set it to be ‘Caramello’.” Then list1’s value is printed, and you can see it has changed. This is the essence of mutability: We are changing our list without creating a new list. On the other hand, editing a string creates a new string, leaving the old one unaltered. For example:

```python
>>> mystring = "hello"
```
>>> list3 = [1, mystring, 3]
>>> list3
[1, 'hello', 3]
>>> mystring = "world"
>>> list3
[1, 'hello', 3]

Of course, this raises the question of how you copy without references when references are the default. The answer, for lists, is that you use the [:] slice, which we looked at earlier. This slices from the first element to the last, inclusive, essentially copying it without references. Here is how that looks:

>>> list4 = ["a", "b", "c"]
>>> list5 = list4[:]
>>> list4 = list4 + ["d"]
>>> list5
['a', 'b', 'c']
>>> list4
['a', 'b', 'c', 'd']

Lists have their own collections of built-in methods, such as sort(), append(), and pop(). The latter two add and remove single elements from the end of the list, with pop() also returning the removed element. For example:

>>> list5 = ["nick", "paul", "julian", "graham"]
>>> list5.sort()
>>> list5
['graham', 'julian', 'nick', 'paul']
>>> list5.pop()
'paul'
>>> list5
['graham', 'julian', 'nick']
>>> list5.append("Rebecca")

In addition, one interesting method of strings returns a list: split(). This takes a character to split by and then gives you a list in which each element is a chunk from the string. For example:

>>> string = "This is a test string";
>>> string.split( " ")
['This', 'is', 'a', 'test', 'string']

Lists are used extensively in Python, although this is slowly changing as the language matures. The way lists are compared and sorted has changed in 3.x, so be sure to check the latest documentation when you attempt to perform these tasks.
Dictionaries

Unlike lists, dictionaries are collections with no fixed order. Instead, they have a key (the name of the element) and a value (the content of the element), and Python places them wherever it needs to for maximum performance. When defining dictionaries, you need to use braces ({ }) and colons (:). You start with an opening brace and then give each element a key and a value, separated by a colon, like this:

```python
>>> mydict = { "perl" : "a language", "php" : "another language" }
>>> mydict
{'php': 'another language', 'perl': 'a language'}
```

This example has two elements, with keys perl and php. However, when the dictionary is printed, we find that php comes before perl—Python hasn’t respected the order in which we entered them. We can index into a dictionary using the normal code:

```python
>>> mydict["perl"]
'a language'
```

However, because a dictionary has no fixed sequence, we cannot take a slice, or index by position.

Like lists, dictionaries are mutable and can also be nested; however, unlike lists, you cannot merge two dictionaries by using +. This is because dictionary elements are located using the key. Therefore, having two elements with the same key would cause a clash. Instead, you should use the update() method, which merges two arrays by overwriting clashing keys.

You can also use the keys() method to return a list of all the keys in a dictionary.

There are subtle differences in how dictionaries are used in 3.x, such as the need to make list calls to produce all values at once so they may be printed. Again, be sure to check the latest documentation as you move ahead, because there are several of these changes in functionality with some tools now behaving differently or even disappearing and other new dictionary tools being added. Some of those features have been backported; for example, Python 2.7 has support for ordered dictionaries, backported from Python 3.1 (see http://docs.python.org/dev/whatsnew/2.7.html#pep-0372).

Conditionals and Looping

So far, we have just been looking at data types, which should show you how powerful Python’s data types are. However, you cannot write complex programs without conditional statements and loops.

Python has most of the standard conditional checks, such as > (greater than), <= (less than or equal to), and == (equal), but it also adds some new ones, such as in. For example, we can use in to check whether a string or a list contains a given character/element:

```python
>>> mystring = "J Random Hacker"
>>> mystring
"J Random Hacker"
```
>>> "r" in mystring
True
>>> "Hacker" in mystring
True
>>> "hacker" in mystring
False

The last example demonstrates how it is case sensitive. We can use the operator for lists, too:

>>> mylist = ["soldier", "sailor", "tinker", "spy"]
>>> "tailor" in mylist
False

Other comparisons on these complex data types are done item by item:

>>> list1 = ["alpha", "beta", "gamma"]
>>> list2 = ["alpha", "beta", "delta"]
>>> list1 > list2
True

list1's first element (alpha) is compared against list2's first element (alpha) and, because they are equal, the next element is checked. That is equal also, so the third element is checked, which is different. The g in gamma comes after the d in delta in the alphabet, so gamma is considered greater than delta and list1 is considered greater than list2.

Loops come in two types, and both are equally flexible. For example, the for loop can iterate through letters in a string or elements in a list:

>>> string = "Hello, Python!"
>>> for s in string: print s,
... Hel l o ,    P y t h o n !

The for loop takes each letter in a string and assigns it to s. This then is printed to the screen using the print command, but note the comma at the end; this tells Python not to insert a line break after each letter. The "..." is there because Python allows you to enter more code in the loop; you need to press Enter again here to have the loop execute.

The same construct can be used for lists:

>>> mylist = ["andi", "rasmus", "zeev"]
>>> for p in mylist: print p
... andi
rasmus
zeev

Without the comma after the print statement, each item is printed on its own line.
The other loop type is the while loop, and it looks similar:

```python
>>> while 1: print "This will loop forever!"
... This will loop forever!
This will loop forever!
This will loop forever!
This will loop forever!
This will loop forever!
(etc)
Traceback (most recent call last):
    File "<stdin>", line 1, in ?
KeyboardInterrupt
>>> 
```

That is an infinite loop (it will carry on printing that text forever), so you need to press Ctrl+C to interrupt it and regain control.

If you want to use multiline loops, you need to get ready to use your Tab key: Python handles loop blocks by recording the level of indent used. Some people find this odious; others admire it for forcing clean coding on users. Most of us, though, just get on with programming!

For example:

```python
>>> i = 0
>>> while i < 3:
...     j = 0
...     while j < 3:
...         print "Pos: " + str(i) + "," + str(j) + ")"
...         j += 1
...     i += 1
...
Pos: (0,0)
Pos: (0,1)
Pos: (0,2)
Pos: (1,0)
Pos: (1,1)
Pos: (1,2)
Pos: (2,0)
Pos: (2,1)
Pos: (2,2)
```

You can control loops using the break and continue keywords. break exits the loop and continues processing immediately afterward, and continue jumps to the next loop iteration.
Again we find many subtle changes in 3.x. Most conditionals and looping work the same, but since we mention it in this section we should note that print is no longer a statement in 3.x and is now a function call. That provides a nice segue to our discussion of functions.

**Functions**

Other languages—such as PHP—read and process an entire file before executing it, which means you can call a function before it is defined because the compiler reads the definition of the function before it tries to call it. Python is different: If the function definition has not been reached by the time you try to call it, you get an error. The reason behind this behavior is that Python actually creates an object for your function, and that in turns means two things. First, you can define the same function several times in a script and have the script pick the right one at runtime. Second, you can assign the function to another name just by using `=`.

Function definition starts with `def`, then the function name, then parentheses and a list of parameters, and then a colon. The contents of a function need to be indented at least one level beyond the definition. So, using function assignment and dynamic declaration, you can write a script that prints the right greeting in a roundabout manner:

```python
>>> def hello_english(Name):
...     print "Hello, " + Name + "!"
...
>>> def hello_hungarian(Name):
...     print "Szia, " + Name + "!"
...
>>> hello = hello_hungarian
>>> hello("Paul")
Szia, Paul!
>>> hello = hello_english
>>> hello("Paul")
```

Notice that function definitions include no type information. Functions are typeless, like we said. The upside of this is that you can write one function to do several things:

```python
>>> def concat(First, Second):
...     return First + Second
...
>>> concat(["python"], ["perl"])
['python', 'perl']
>>> concat("Hello, ", "world!")
'Hello, world!'
```

That demonstrates how the `return` statement sends a value back to the caller, but also how a function can do one thing with lists and another thing with strings. The magic here is being accomplished by the objects. We write a function that tells two objects to add themselves together, and the objects intrinsically know how to do that. If they
don’t—if, perhaps, the user passes in a string and an integer—Python catches the error for us. However, it is this hands off, “let the objects sort themselves out” attitude that makes functions so flexible. Our concat() function could conceivably concatenate strings, lists, or *zonks*—a data type someone created herself that allows adding. The point is that we do not limit what our function can do—tacky as it might sound, the only limit is your imagination!

**Object Orientation**

After having read this far, you should not be surprised to hear that Python’s object orientation is flexible and likely to surprise you if you have been using C-like languages for several years.

The best way to learn Python object-oriented programming (OOP) is to just do it. So, here is a basic script that defines a class, creates an object of that class, and calls a function:

```python
class Dog(object):
    def bark(self):
        print "Woof!"

fluffy = Dog()
fluffy.bark()
```

Defining a class starts, predictably, with the `class` keyword followed by the name of the class you are defining and a colon. The contents of that class need to be indented one level so that Python knows where it stops. Note that the `object` inside parentheses is there for object inheritance, which is discussed later. For now, the least you need to know is that if your new class is not based on an existing class, you should put `object` inside parentheses as shown in the previous code.

Functions inside classes work in much the same way as normal functions do (although they are usually called *methods*); the main difference is that they should all take at least one parameter, usually called `self`. This parameter is filled with the name of the object the function was called on, and you need to use it explicitly.

Creating an instance of a class is done by assignment. You do not need any `new` keyword, as in some other languages—providing the parentheses makes the creation known. Calling a function of that object is done using a period, the name of the class to call, with any parameters being passed inside parentheses.

**Class and Object Variables**

Each object has its own set of functions and variables, and you can manipulate those variables independently of objects of the same type. In addition, some class variables are set to a default value for all classes and can be manipulated globally.
This script demonstrates two objects of the dog class being created, each with its own name:

```python
class Dog(object):
    name = "Lassie"
    def bark(self):
        print self.name + " says 'Woof!'"
    def set_name(self, name):
        self.name = name

fluffy = Dog()
fluffy.bark()

poppy = Dog()
poppy.set_name("Poppy")
poppy.bark()
```

That outputs the following:

```
Lassie says 'Woof!'
Poppy says 'Woof!'
```

There, each dog starts with the name Lassie, but it gets customized. Keep in mind that Python assigns by reference by default, meaning each object has a reference to the class’s name variable, and as we assign that with the set_name() method, that reference is lost. This means that any references we do not change can be manipulated globally. Thus, if we change a class’s variable, it also changes in all instances of that class that have not set their own value for that variable. For example:

```python
class Dog(object):
    name = "Lassie"
    color = "brown"

fluffy = Dog()
poppy = Dog()
print fluffy.color
Dog.color = "black"
print poppy.color
fluffy.color = "yellow"
print fluffy.color
print poppy.color
```

So, the default color of dogs is brown—both the fluffy and poppy Dog objects start off as brown. Then, using Dog.color, we set the default color to be black, and because neither of the two objects has set its own color value, they are updated to be black. The third-to-last line uses poppy.color to set a custom color value for the poppy object—poppy becomes yellow, whereas fluffy and the dog class in general remain black.
Constructors and Destructors

To help you automate the creation and deletion of objects, you can easily override two default methods: __init__ and __del__. These are the methods called by Python when a class is being instantiated and freed, known as the constructor and destructor, respectively.

Having a custom constructor is great for when you need to accept a set of parameters for each object being created. For example, you might want each dog to have its own name on creation, and you could implement that with this code:

```python
class Dog(object):
    def __init__(self, name):
        self.name = name

fluffy = Dog("Fluffy")
print fluffy.name
```

If you do not provide a name parameter when creating the dog object, Python reports an error and stops. You can, of course, ask for as many constructor parameters as you want, although it is usually better to ask only for the ones you need and have other functions to fill in the rest.

On the other side of things is the destructor method, which allows you to have more control over what happens when an object is destroyed. Using the two, we can show the life cycle of an object by printing messages when it is created and deleted:

```python
class Dog(object):
    def __init__(self, name):
        self.name = name
        print self.name + " is alive!"
    def __del__(self):
        print self.name + " is no more!"

fluffy = Dog("Fluffy")
```

The destructor is there to give you the chance to free up resources allocated to the object, or perhaps log something to a file. Note that although it is possible to override the __del__ method, it is a very dangerous idea because it is not guaranteed that __del__ methods are called for objects that still exist when the interpreter exits. The official Python documentation explains this well at http://docs.python.org/reference/datamodel.html#object.__del__.

Class Inheritance

Python allows you to reuse your code by inheriting one class from one or more others. For example, lions, tigers, and bears are all mammals and so share a number of similar properties. In that scenario, you would not want to have to copy and paste functions between them; it would be smarter (and easier!) to have a mammal class that defines all the shared functionality and then inherit each animal from that.
Consider the following code:

```python
class Car(object):
    color = "black"
    speed = 0
    def accelerate_to(self, speed):
        self.speed = speed
    def set_color(self, color):
        self.color = color

mycar = Car()
print mycar.color
```

That creates a `Car` class with a default color and also provides a `set_color()` function so people can change their own colors. Now, what do you drive to work? Is it a car? Sure it is, but chances are it is a Ford, or a Dodge, or a Jeep, or some other make—you don't get cars without a make. On the other hand, you do not want to have to define a class `Ford`, give it the methods `accelerate_to()`, `set_color()`, and however many other methods a basic car has and then do the same thing for `Ferrari`, `Nissan`, and so on.

The solution is to use inheritance: Define a `car` class that contains all the shared functions and variables of all the makes and then inherit from that. In Python, you do this by putting the name of the class from which to inherit inside parentheses in the class declaration, like this:

```python
class Car(object):
    color = "black"
    speed = 0
    def accelerate_to(self, speed):
        self.speed = speed
    def set_color(self, color):
        self.color = color

class Ford(Car): pass
class Nissan(Car): pass

mycar = Ford()
print mycar.color
```

The `pass` directive is an empty statement—it means our class contains nothing new. However, because the Ford and Nissan classes inherit from the `car` class, they get `color`, `speed`, `accelerate_to()`, and `set_color()` provided by their parent class. Note that we do not need `object` after the class names for `Ford` and `Nissan` because they are inherited from an existing class: `car`.

By default, Python gives you all the methods the parent class has, but you can override that by providing new implementations for the classes that need them. For example:

```python
class Modelt(car):
    def set_color(self, color):
        print "Sorry, Model Ts only come in black!"
```

Download from www.eBookTM.com
myford Ford()
Ford.set_color("green")
mycar = Modelt()
mycar.set_color("green")

The first car is created as a Ford, so set_color() will work fine because it uses the method from the car class. However, the second car is created as a Model T, which has its own set_color() method, so the call will fail.

This provides an interesting scenario: What do you do if you have overridden a method and yet want to call the parent’s method also? If, for example, changing the color of a Model T was allowed but just cost extra, we would want to print a message saying, “You owe $50 more,” but then change the color. To do this, we need to use the class object from which our current class is inherited—Car in this case. Here’s an example:

class Modelt(Car):
    def set_color(self, color):
        print "You owe $50 more"
        Car.set_color(self, color)

mycar = Modelt()
mycar.set_color("green")
print mycar.color

That prints the message and then changes the color of the car.

The Standard Library and the Python Package Index

A default Python install includes many modules (blocks of code) that enable you to interact with the operating system, open and manipulate files, parse command-line options, perform data hashing and encryption, and much more. This is one of the reasons most commonly cited when people are asked why they like Python so much—it comes stocked to the gills with functionality you can take advantage of immediately. In fact, the number of modules included in the Standard Library is so high that entire books have been written about them.

For unofficial scripts and add-ons for Python, the recommended starting place is called the Python Package Index (PyPI) at http://pypi.python.org/pypi. There you can find well over 10,000 public scripts and code examples for everything from mathematics to games.

Reference

- www.python.org—The Python website is packed with information and updated regularly. This should be your first stop, if only to read the latest Python news.
- www.jython.org—Python also has an excellent Java-based interpreter to allow it to run on other platforms. If you prefer Microsoft .NET, try http://www.ironpython.com.
www.pythonline.com—Guido van Rossum borrowed the name for his language from *Monty Python’s Flying Circus*, and as a result many Python code examples use oblique *Monty Python* references (spam and eggs are quite common, for example). A visit to the official *Monty Python* site to hone your Python knowledge is highly recommended!

www.zope.org—The home page of the Zope Content Management System (CMS), it’s one of the most popular CMSes around and, more important, written entirely in Python.

If you want a book, we recommend starting with *Learning Python, by Mark Lutz* (O’Reilly), and for advanced work move to *Programming Python, also by Mark Lutz* (O’Reilly).
This chapter introduces you to the world of PHP programming, from the point of view of using it as a web scripting language and as a command-line tool. PHP originally stood for personal home page because it was a collection of Perl scripts designed to ease the creation of guest books, message boards, and other interactive scripts commonly found on home pages. However, since those early days, it has received two major updates (PHP 3 and PHP 4), plus a substantial revision in PHP 5, which is the version bundled with Ubuntu.

Part of the success of PHP has been its powerful integration with databases—it's earliest uses nearly always took advantage of a database back end. In PHP 5, two big new data storage mechanisms were introduced: SQLite, which is a powerful and local database system, and SimpleXML, which is an application programming interface (API) designed to make XML parsing and querying easy. As you will see over time, the PHP developers did a great job: Both SQLite and SimpleXML are easy to learn and use.

NOTE

Many packages for PHP are available from the Ubuntu repositories. The basic package is just called php5, but you might also want to add extensions such as php5-ldap, php5-mysql, or php5-pgsql.
Introduction to PHP

In terms of the way it looks, PHP is a cross between Java and Perl, having taken the best aspects of both and merged them successfully into one language. The Java parts include a powerful object-orientation system, the capability to throw program exceptions, and the general style of writing that both languages borrowed from C. Borrowed from Perl is the “it should just work” mentality where ease of use is favored over strictness. As a result, you will find a lot of “there is more than one way to do it” in PHP. This also means that it is possible to accomplish tasks in ways that are less than ideal or without consideration for good security. Many criticize PHP for this, but for simple tasks or if written carefully, it can be a pretty good language and is easy to understand and use, especially for quick website creation.

Entering and Exiting PHP Mode

Unlike PHPs predecessors, you embed your PHP code inside your HTML as opposed to the other way around. Before PHP, many websites had standard HTML pages for most of their content, linking to Perl CGI pages to do back-end processing when needed. With PHP, all your pages are capable of processing and containing HTML. This is a huge factor in PHPs popularity.

Each .php file is processed by PHP that looks for code to execute. PHP considers all the text it finds to be HTML until it finds one of four things:

- <?php
- <?
- <%
- <script language="php">

The first option is the preferred method of entering PHP mode because it is guaranteed to work.

When in PHP mode, you can exit it by using ?> (for <?php and <?); %> for <% or </script> (for <script language="php">). This code example demonstrates entering and exiting PHP mode:

In HTML mode
<?php
  echo "In PHP mode";
?>
In HTML mode
In <?php echo "PHP"; ?> mode
Variables

All variables in PHP start with a dollar sign ($). Unlike many other languages, PHP does not have different types of variable for integers, floating-point numbers, arrays, or Booleans. They all start with a $, and all are interchangeable. As a result, PHP is a weakly typed language, which means you do not declare a variable as containing a specific type of data; you just use it however you want to.

Save the code in Listing 29.1 into the script ubuntu1.php.

**LISTING 29.1 Testing Types in PHP**

```php
<?php
  $i = 10;
  $j = "10";
  $k = "Hello, world";
  echo $i + $j;
  echo $i + $k;
?>
```

To run that script, bring up a console and browse to where you saved it. Then type this command:

```
$ php ubuntu1.php
```

If PHP is installed correctly, you should see the output **2010**, which is really two things. The 20 is the result of **10 + 10** ($i plus $j), and the 10 is the result of adding 10 to the text string **Hello, world**. Neither of those operations are really straightforward. Whereas $i is set to the number 10, $j is actually set to be the text value "10", which is not the same thing. Adding 10 to 10 gives 20, as you would imagine, but adding 10 to "10" (the string) forces PHP to convert $j to an integer on-the-fly before adding it.

Running $i + $k adds another string to a number, but this time the string is **Hello, world** and not just a number inside a string. PHP still tries to convert it, though, and converting any non-numeric string into a number converts it to 0. So, the second echo statement ends up saying $i + 0.

As you should have guessed by now, calling echo outputs values to the screen. Right now, that prints directly to your console, but internally PHP has a complex output mechanism that enables you to print to a console, send text through Apache to a web browser, send data over a network, and more.

Now that you have seen how PHP handles variables of different types, it is important that you understand the selection of types available to you, as shown in Table 29.1.
The first four can be thought of as simple variables, and the last three as complex variables. Arrays are simply collections of variables. You might have an array of numbers (the ages of all the children in a class); an array of strings (the names of all Wimbledon tennis champions); or even an array of arrays, known as a multidimensional array. Arrays are covered in more depth in the next section because they are unique in the way in which they are defined.

Objects are used to define and manipulate a set of variables that belong to a unique entity. Each object has its own personal set of variables, as well as functions that operate on those variables. Objects are commonly used to model real-world things. You might define an object that represents a TV, with variables such as $CurrentChannel (probably an integer), $SupportsHiDef (a Boolean), and so on.

Of all the complex variables, the easiest to grasp are resources. PHP has many extensions available to it that allow you to connect to databases, manipulate graphics, or even make calls to Java programs. Because they are all external systems, they need to have types of data unique to them that PHP cannot represent using any of the six other data types. So, PHP stores their custom data types in resources—data types that are meaningless to PHP but can be used by the external libraries that created them.

### Arrays

Arrays are one of our favorite parts of PHP because the syntax is smart and easy to read and yet manages to be as powerful as you could want. There are four pieces of jargon you need to know to understand arrays:

- An array is made up of many elements.
- Each element has a key that defines its place in the array. An array can have only one element with a given key.
- Each element also has a value, which is the data associated with the key.
- Each array has a cursor, which points to the current key.

<table>
<thead>
<tr>
<th>Type</th>
<th>Stores</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>Whole numbers; for example, 1, 9, or 324809873</td>
</tr>
<tr>
<td>float</td>
<td>Fractional numbers; for example, 1.1, 9.09, or 3.141592654</td>
</tr>
<tr>
<td>string</td>
<td>Characters; for example, “a”, “sfdgh”, or “Ubuntu Unleashed”</td>
</tr>
<tr>
<td>boolean</td>
<td>True or false</td>
</tr>
<tr>
<td>array</td>
<td>Several variables of any type</td>
</tr>
<tr>
<td>resource</td>
<td>Any external data</td>
</tr>
</tbody>
</table>
The first three are used regularly; the last one less often. The array cursor is covered later in this chapter in the section “Basic Functions,” but we will look at the other three now. With PHP, your keys can be virtually anything: integers, strings, objects, or other arrays. You can even mix and match the keys so that one key is an array; another is a string, and so on. The one exception to all this is floating-point numbers: You cannot use floating-point numbers as keys in your arrays.

There are two ways of adding values to an array: with the [ ] operator, which is unique to arrays; and with the array() pseudo-function. You should use [ ] when you want to add items to an existing array and use array() to create a new array.

To sum all this up in code, Listing 29.2 shows a script that creates an array without specifying keys, adds various items to it both without keys and with keys of varying types, does a bit of printing, and then clears the array.

**LISTING 29.2  Manipulating Arrays**

```php
<?php
    $myarr = array(1, 2, 3, 4);
    $myarr[4] = "Hello";
    $myarr[] = "World!";
    $myarr["elephant"] = "Wombat";
    $myarr["foo"] = array(5, 6, 7, 8);

    echo $myarr[2];
    echo $myarr["elephant"];
    echo $myarr["foo"][1];

    $myarr = array();
?>
```

The initial array is created with four elements, to which we assign the values 1, 2, 3, and 4. Because no keys are specified, PHP automatically assigns keys for us starting at 0 and counting upward—giving keys 0, 1, 2, and 3. Then we add a new element with the [ ] operator, specifying 4 as the key and "Hello" as the value. Next, [ ] is used again to add an element with the value "World!" and no key and then again to add an element with the key "elephant" and the value "Wombat". The line after that demonstrates using a string key with an array value—an array inside an array (a multidimensional array).

The next three lines demonstrate reading back from an array, first using a numeric key, then using a string key, and then using a string key and a numeric key. Remember, the "foo" element is an array in itself, so that third reading line retrieves the array and then prints the second element (arrays start at 0, remember). The last line blanks the array by simply using array() with no parameters, which creates an array with elements and assigns it to $myarr.
The following is an alternative way of using `array()` that allows you to specify keys along with their values:

```php
$myarr = array("key1" => "value1", "key2" => "value2",
7 => "foo", 15 => "bar");
```

Which method you choose really depends on whether you want specific keys or want PHP to pick them for you.

### Constants

Constants are frequently used in functions that require specific values to be passed in. For example, a popular function is `extract()`, which takes all the values in an array and places them into variables in their own right. You can choose to change the name of the variables as they are extracted using the second parameter—send it a 0 and it overwrites variables with the same names as those being extracted, send it a 1 and it skips variables with the same names, send it 5 and it prefixes variables only if they exist already, and so on. Of course, no one wants to have to remember a lot of numbers for each function, so you can instead use `EXTR_OVERWRITE` for 0, `EXTR_SKIP` for 1, `EXTR_PREFIX_IF_EXISTS` for 5, and so on, which is much easier.

You can create constants of your own by using the `define()` function. Unlike variables, constants do not start with a dollar sign. Code to define a constant looks like this:

```php
<?php
    define("NUM_SQUIRRELS", 10);
    define("PLAYER_NAME", "Jim");
    define("NUM_SQUIRRELS_2", NUM_SQUIRRELS);
    echo NUM_SQUIRRELS_2;
?>
```

That script demonstrates how you can set constants to numbers, strings, or even the value of other constants, although that doesn’t really get used much!

### References

Using the equal sign (=) copies the value from one variable to another so they both have their own copy of the value. Another option here is to use references, which is where a variable does not have a value of its own; instead, it points to another variable. This enables you to share values and have variables mutually update themselves.

To copy by reference, use the & symbol, as follows:

```php
<?php
    $a = 10;
    $b = &$a;
    echo $a . "\n";
    echo $b . "\n";
?>
```
Introduction to PHP

```php
$a = 20;
echo $a . "\n";
echo $b . "\n";

$b = 30;
echo $a . "\n";
echo $b . "\n";
?>
```

If you run that script, you will see that updating $a also updates $b, but also that updating $b updates $a, too.

Comments

Adding short comments to your code, is recommended and usually a requirement in larger software houses. In PHP you have three options for commenting style: //, /* */ , and #. The first option (two slashes) instructs PHP to ignore everything until the end of the line. The second (a slash and an asterisk) instructs PHP to ignore everything until it reaches */. The last (a hash symbol) works like // and is included because it is common among shell scripting languages.

This code example demonstrates the difference between // and /* */:

```php
<?php
    echo "This is printed!";
    // echo "This is not printed";
    echo "This is printed!";
    /* echo "This is not printed";
    echo "This is not printed either"; */
?>
```

It is generally preferred to use // because it is a known quantity. On the other hand, it is easy to introduce coding errors with /* */ by losing track of where a comment starts and ends.

NOTE

Contrary to popular belief, having comments in your PHP script has almost no effect on the speed at which the script executes. What little speed difference exists is wholly removed if you use a code cache.

Escape Sequences

Some characters cannot be typed, and yet you will almost certainly want to use some of them from time to time. For example, you might want to use an ASCII character for new line, but you can’t type it. Instead, you need to use an escape sequence: \n. Similarly, you can print a carriage return character with \r. It’s important to know both of these because,
on the Windows platform, you need to use `\r\n` to get a new line. If you do not plan to run your scripts anywhere else, you need not worry about this!

Going back to the first script we wrote, recall that it printed 2010 because we added 10 + 10 and then 10 + 0. We can rewrite that using escape sequences, like this:

```php
<?php
    $i = 10;
    $j = "10";
    $k = "Hello, world"
    echo $i + $j;
    echo "\n";
    echo $i + $k;
    echo "\n";
?>
```

This time PHP prints a new line after each of the numbers, making it obvious that the output is 20 and 10 rather than 2010. Note that the escape sequences must be used in double quotation marks because they will not work in single quotation marks.

Three common escape sequences are `\`, which means “ignore the backslash”; `\"`, which means “ignore the double quote”; and `\'`, which means “ignore the single quote.” This is important when strings include quotation marks inside them. If we had a string such as "are you really Bill O'Reilly?", which has a single quotation mark in, this code would not work:

```php
<?php
    echo 'Are you really Bill O'Reilly?';
?>
```

PHP would see the opening quotation mark, read all the way up to the O in O'Reilly, and then see the quotation mark following the O as being the end of the string. The Reilly? part would appear to be a fragment of text and would cause an error. You have two options here: You can either surround the string in double quotation marks or escape the single quotation mark with `\`.

If you choose the escaping route, it will look like this:

```php
echo 'Are you really Bill O\'Reilly?';
```

Although they are a clean solution for small text strings, be careful with overusing escape sequences. HTML is particularly full of quotation marks, and escaping them can get messy:

```php
$mystring = "<img src="foo.png" alt="My picture" width="100" height="200"/>
```

In that situation, you are better off using single quotation marks to surround the text simply because it is a great deal easier on the eye!
Variable Substitution

PHP allows you to define strings using three methods: single quotation marks, double quotation marks, or heredoc notation. Heredoc isn’t discussed here because it’s fairly rare compared to the other two methods, but single quotation marks and double quotation marks work identically, with one minor exception—variable substitution.

Consider the following code:

```php
<?php
    $age = 25
    echo "You are ";
    echo $age;
?>
```

That is a particularly clumsy way to print a variable as part of a string. Fortunately, if you put a variable inside a string, PHP performs variable substitution, replacing the variable with its value. That means we can rewrite the code like this:

```php
<?php
    $age = 25
    echo "You are $age";
?>
```

The output is the same. The difference between single quotation marks and double quotation marks is that single-quoted strings do not have their variables substituted. Here’s an example:

```php
<?php
    $age = 25
    echo "You are $age";
    echo 'You are $age';
?>
```

The first `echo` prints “You are 25”, but the second one prints "You are $age".

Operators

Now that we have data values to work with, we need some operators to use, too. We have already used + to add variables together, but many others in PHP handle arithmetic, comparison, assignment, and other operators. Operator is just a fancy word for something that performs an operation, such as addition or subtraction. However, operand might be new to you. Consider this operation:

```php
$a = $b + c;
```

In this operation, = and + are operators, and $a, $b, and $c are operands. Along with +, you will also already know – (subtract), * (multiply), and / (divide), but Table 29.2 provides some more.
At least 10 other operators are not listed; to be fair, however, you’re unlikely to use them. Even some of the ones in this list are used infrequently—bitwise AND, for example. Having said that, the bitwise OR operator is used regularly because it allows you to combine values.

Here is a code example demonstrating some of the operators:

```php
<?php
    $i = 100;
    $i++; // $i is now 101
    $i++; // $i is now 101
```
$i--; // $i is now 100 again
$i += 10; // $i is 110
$i = $i / 2; // $i is 55
$j = $i; // both $j and $i are 55
$i = $j % 11; // $i is 0

The last line uses modulus, which takes some people a little bit of effort to understand. The result of $i % 11 is 0 because $i is set to 55 and modulus works by dividing the left operand (55) by the right operand (11) and returning the remainder. 55 divides by 11 exactly 5 times, and so has the remainder 0.

The concatenation operator, a period, sounds scarier than it is: It just joins strings together. For example:

```php
<?php
    echo "Hello, ". "world!";
    echo "Hello, world!" . "\n";
?>
```

There are two “special” operators in PHP that are not covered here and yet are used frequently. Before we look at them, though, it’s important that you see how the comparison operators (such as <, <=, and !=) are used inside conditional statements.

## Conditional Statements

In a **conditional statement** you instruct PHP to take different actions depending on the outcome of a test. For example, you might want PHP to check whether a variable is greater than 10 and, if so, print a message. This is all done with the `if` statement, which looks like this:

```php
if (your condition) {
    // action to take if condition is true
} else {
    // optional action to take otherwise
}
```

The `your condition` part can be filled with any number of conditions you want PHP to evaluate, and this is where the comparison operators come into their own. For example:

```php
if ($i > 10) {
    echo "11 or higher";
} else {
```
PHP looks at the condition and compares $i to 10. If it is greater than 10, it replaces the whole operation with 1; otherwise, it replaces it with 0. So, if $i is 20, the result looks like this:

```php
if (1) {
    echo "11 or higher";
} else {
    echo "10 or lower";
}
```

In conditional statements, any number other than 0 is considered to be equivalent to the Boolean value true, so if (1) always evaluates to true. There is a similar case for strings—if your string has any characters in, it evaluates to true, with empty strings evaluating to false. This is important because you can then use that 1 in another condition through && or || operators. For example, if you want to check whether $i is greater than 10 but less than 40, you could write this:

```php
if ($i > 10 && $i < 40) {
    echo "11 or higher";
} else {
    echo "10 or lower";
}
```

If we presume that $i is set to 50, the first condition ($i, 10) is replaced with 1 and the second condition ($i < 40) is replaced with 0. Those two numbers are then used by the && operator, which requires both the left and right operands to be true. Whereas 1 is equivalent to true, 0 is not, so the && operand is replaced with 0 and the condition fails.

=, ==, ===, and similar operators are easily confused and often the source of programming errors. The first, a single equal sign, assigns the value of the right operand to the left operand. However, all too often you see code like this:

```php
if ($i = 10) {
    echo "The variable is equal to 10!";
} else {
    echo "The variable is not equal to 10";
}
```

That is incorrect. Rather than checking whether $i is equal to 10, it assigns 10 to $i and returns true. What is needed is ==, which compares two values for equality. In PHP, this is extended so that there is also === (three equal signs), which checks whether two values are identical—more than just equal.

The difference is slight but important: If you have a variable with the string value "10" and compare it against the number value of 10, they are equal. Thus, PHP converts the type and checks the numbers. However, they are not identical. To be considered identical,
the two variables must be equal (that is, have the same value) and be of the same data type (that is, both are strings, both are integers, and so on).

**NOTE**

It is common practice to put function calls in conditional statements rather than direct comparisons. For example:

```php
if (do_something()) {

If the do_something() function returns true (or something equivalent to true, such as a nonzero number), the conditional statement evaluates to true.
```

**Special Operators**

The ternary operator and the execution operator work differently from those we have seen so far. The ternary operator is rarely used in PHP, thankfully, because it is really just a condensed conditional statement. Presumably it arose through someone needing to make a code occupy as little space as possible because it certainly does not make PHP code any easier to read!

The ternary operator works like this:

```php
$age_description = ($age < 18) ? "child" : "adult";
```

Without explanation, that code is essentially meaningless; however, it expands into the following five lines of code:

```php
if ($age < 18) {
    $age_description = "child";
} else {
    $age_description = "adult";
}
```

The ternary operator is so named because it has three operands: a condition to check ($age < 18 in the previous code), a result if the condition is true ("child"), and a result if the condition is false ("adult"). Although we hope you never have to use the ternary operator, it is at least important to know how it works in case you stumble across it.

The other special operator is the execution operator, which is the backtick symbol, `. The position of the backtick key varies depending on your keyboard, but it is likely to be just to the left of the 1 key (above Tab). The execution operator executes the program inside the back ticks, returning any text the program outputs. For example:

```php
<?php
    $i = 'ls -l';
    echo $i;
?>
```
That executes the `ls` program, passing in `-l` (a lowercase `L`) to get the long format, and stores all its output in `$i`. You can make the command as long or as complex as you like, including piping to other programs. You can also use PHP variables inside the command.

**Switching**

Having multiple `if` statements in one place is ugly, slow, and prone to errors. Consider the code in Listing 29.3.

**LISTING 29.3 How Multiple Conditional Statements Lead to Ugly Code**

```php
<?php
$cat_age = 3;

if ($cat_age == 1) {
    echo "Cat age is 1";
} else {
    if ($cat_age == 2) {
        echo "Cat age is 2";
    } else {
        if ($cat_age == 3) {
            echo "Cat age is 3";
        } else {
            if ($cat_age == 4) {
                echo "Cat age is 4";
            } else {
                echo "Cat age is unknown";
            }
        }
    }
}
?>
```

Even though it certainly works, it is a poor solution to the problem. Much better is a `switch/case` block, which transforms the previous code into what's shown in Listing 29.4.

**LISTING 29.4 Using a switch/case Block**

```php
<?php
$cat_age = 3;

switch ($cat_age) {
    case 1:
        echo "Cat age is 1";
        break;
    
```
case 2:
    echo "Cat age is 2";
    break;
case 3:
    echo "Cat age is 3";
    break;
case 4:
    echo "Cat age is 4";
    break;
default:
    echo "Cat age is unknown";
}
?>

Although it is only slightly shorter, it is a great deal more readable and much easier to maintain. A switch/case group is made up of a switch() statement in which you provide the variable you want to check, followed by numerous case statements. Notice the break statement at the end of each case. Without that, PHP would execute each case statement beneath the one it matches. Calling break causes PHP to exit the switch/case. Notice also that there is a default case at the end that catches everything that has no matching case.

It is important that you do not use case default: but merely default:. Also, it is the last case label, so it has no need for a break statement because PHP exits the switch/case block there anyway.

**Loops**

PHP has four ways you can execute a block of code multiple times: while, for, foreach, and do...while. Of the four, only do...while sees little use; the others are popular and you will certainly encounter them in other people’s scripts.

The most basic loop is the while loop, which executes a block of code for as long as a given condition is true. So, we can write an infinite loop—a block of code that continues forever—with this PHP:

```php
<?php
    $i = 10;
    while ($i >= 10) {
        $i += 1;
        echo $i;
    }
?>
```

The loop block checks whether $i is greater or equal to 10 and, if that condition is true, adds 1 to $i and prints it. Then it goes back to the loop condition again. Because $i starts
at 10 and we only ever add numbers to it, that loop continues forever. With two small changes, we can make the loop count down from 10 to 0:

```php
<?php
$i = 10;
while ($i >= 0) {
    $i -= 1;
    echo $i;
}
?>
```

So, this time we check whether $i is greater than or equal to 0 and subtract 1 from it with each loop iteration. while loops are typically used when you are unsure of how many times the code needs to loop because while keeps looping until an external factor stops it.

With a for loop, you specify precise limits on its operation by giving it a declaration, a condition, and an action. That is, you specify one or more variables that should be set when the loop first runs (the declaration), you set the circumstances that will cause the loop to terminate (the condition), and you tell PHP what it should change with each loop iteration (the action). That last part is what really sets a for loop apart from a while loop: You usually tell PHP to change the condition variable with each iteration.

We can rewrite the script that counts down from 10 to 0 using a for loop:

```php
<?php
for($i = 10; $i >= 0; $i -= 1) {
    echo $i;
}
?>
```

This time we do not need to specify the initial value for $i outside the loop, and neither do we need to change $i inside the loop—it is all part of the for statement. The actual amount of code is really the same, but for this purpose the for loop is arguably tidier and therefore easier to read. With the while loop, the $i variable was declared outside the loop and so was not explicitly attached to the loop.

The third loop type is foreach, which is specifically for arrays and objects, although it is rarely used for anything other than arrays. A foreach loop iterates through each element in an array (or each variable in an object), optionally providing both the key name and the value.

In its simplest form, a foreach loop looks like this:

```php
<?php
foreach($myarr as $value) {
    echo $value;
}
?>
```
This loops through the $myarr array we created earlier, placing each value in the $value variable. We can modify that so we get the keys as well as the values from the array, like this:

```php
<?php
    foreach($myarr as $key => $value) {
        echo "$key is set to $value\n";
    }
?>
```

As you can guess, this time the array keys go in $key and the array values go in $value.

One important characteristic of the `foreach` loop is that it goes from the start of the array to the end and then stops—and by *start* we mean the first item to be added rather than the lowest index number. This script shows this behavior:

```php
<?php
    $array = array(6 => "Hello", 4 => "World",
                   2 => "Wom", 0 => "Bat");
    foreach($array as $key => $value) {
        echo "$key is set to $value\n";
    }
?>
```

If you try this script, you will see that `foreach` prints the array in the original order of 6, 4, 2, 0 rather than the numeric order of 0, 2, 4, 6.

The `do...while` loop works like the `while` loop, with the exception that the condition appears at the end of the code block. This small syntactical difference means a lot, though, because a `do...while` loop is always executed at least once. Consider this script:

```php
<?php
    $i = 10;
    do {
        $i -= 1;
        echo $i;
    } while ($i < 10);
?>
```

Without running the script, what do you think it will do? One possibility is that it will do nothing; $i is set to 10, and the condition states that the code must loop only while $i is less than 10. However, a `do...while` loop always executes once, so what happens is that $i is set to 10 and PHP enters the loop, decrements $i, prints it, and then checks the condition for the first time. At this point, $i is indeed less than 10, so the code loops, $i is decremented again, the condition is rechecked, $i is decremented again, and so on. This is in fact an infinite loop, and so should be avoided!

If you ever want to exit a loop before it has finished, you can use the same `break` statement, which we used earlier to exit a `switch/case` block. This becomes more interesting if
you find yourself with *nested* loops—loops inside of loops. This is a common situation to be in. For example, you might want to loop through all the rows in a chessboard and, for each row, loop through each column. Calling `break` exits only one loop or `switch/case`, but you can use `break 2` to exit two loops or `switch/cases`, or `break 3` to exit three, and so on.

**Including Other Files**

Unless you are restricting yourself to the simplest programming ventures, you will want to share code among your scripts at some point. The most basic need for this is to have a standard header and footer for your website, with only the body content changing. However, you might also find yourself with a small set of custom functions you use frequently, and it would be an incredibly bad move to simply copy and paste the functions into each of the scripts that use them.

The most common way to include other files is with the `include` keyword. Save this script as `include1.php`:

```php
<?php
    for($i = 10; $i >= 0; $i -= 1) {
        include "echo_i.php";
    }
?>
```

Then save this script as `echo_i.php`:

```php
<?php
    echo $i;
?>
```

If you run `include1.php`, PHP loops from 10 to 0 and includes `echo_i.php` each time. For its part, `echo_i.php` just prints the value of `$i`, which is a crazy way of performing an otherwise simple operation, but it does demonstrate how included files share data. Note that the `include` keyword in `include1.php` is inside a PHP block, but we reopen PHP inside `echo_i.php`. This is important because PHP exits PHP mode for each new file, so you always have a consistent entry point.

**Basic Functions**

PHP has a vast number of built-in functions that enable you to manipulate strings, connect to databases, and more. There is not room here to cover even 10 percent of the functions; for more detailed coverage of functions, check the “Reference” section at the end of this chapter.

**Strings**

Several important functions are used for working with strings, and there are many more less frequently used ones for which there is not enough space here. We are going to look at the most important here, ordered by difficulty—easiest first!
The easiest function is `strlen()`, which takes a string as its parameter and returns the number of characters in there, like this:

```php
<?php
    $ourstring = " The Quick Brown Box Jumped Over The Lazy Dog ";
    echo strlen($ourstring);
?>
```

We will be using that same string in subsequent examples to save space. If you execute that script, it outputs 48 because 48 characters are in the string. Note the 2 spaces on either side of the text, which pad the 44-character phrase up to 48 characters.

We can fix that padding with the `trim()` function, which takes a string to trim and returns it with all the whitespace removed from either side. This is a commonly used function because all too often you encounter strings that have an extra new line at the end or a space at the beginning. This cleans it up perfectly.

Using `trim()`, we can turn our 48-character string into a 44-character string (the same thing, without the extra spaces), like this:

```php
echo trim($ourstring);
```

Keep in mind that `trim()` returns the trimmed string, so that outputs “The Quick Brown Box Jumped Over The Lazy Dog”. We can modify that so `trim()` passes its return value to `strlen()` so that the code trims it and then outputs its trimmed length:

```php
echo strlen(trim($ourstring));
```

PHP always executes the innermost functions first, so the previous code takes `$ourstring`, passes it through `trim()`, uses the return value of `trim()` as the parameter for `strlen()`, and prints it.

Of course, everyone knows that boxes do not jump over dogs—the usual phrase is “the quick brown fox.” Fortunately, there is a function to fix that problem: `str_replace()`.

Note that it has an underscore in it; PHP is inconsistent on this matter, so you really need to memorize the function name.

The `str_replace()` function takes three parameters: the text to search for, the text to replace it with, and the string you want to work with. When working with search functions, people often talk about *needles* and *haystacks*—in this situation, the first parameter is the needle (the thing to find), and the third parameter is the haystack (what you are searching through).

So, we can fix our error and correct *box* to *fox* with this code:

```php
echo str_replace("Box", "Fox", $ourstring);
```

There are two little addendums to make here. First, note that we have specified “Box” as opposed to “box” because that is how it appears in the text. The `str_replace()` function is a *case-sensitive* function, which means it does not consider “Box” to be the same as
“box”. If you want to do a non-case-sensitive search and replace, you can use the 
stri_replace() function, which works in the same way.

The second addendum is that, because we are actually changing only one character (B to 
F), we need not use a function at all. PHP enables you to read (and change) individual 
characters of a string by specifying the character position inside braces ({ and }). As with 
arrays, strings are zero based, which means in the $ourstring variable $ourstring{0} is T, 
$ourstring{1} is h, $ourstring{2} is e, and so on. We could use this instead of 
str_replace(), like this:

```php
<?php
    $ourstring = "The Quick Brown Box Jumped Over The Lazy Dog ";
    $ourstring{18} = "F";
    echo $ourstring;
?>
```

You can extract part of a string using the substr() function, which takes a string as its 
first parameter, a start position as its second parameter, and an optional length as its third 
parameter. Optional parameters are common in PHP. If you do not provide them, PHP 
assumes a default value. In this case, if you specify only the first two parameters, PHP 
copies from the start position to the end of the string. If you specify the third parameter, 
PHP copies that many characters from the start.

We can write a simple script to print “Lazy Dog” by setting the start position to 38, which, 
remembering that PHP starts counting string positions from 0, copies from the 39th char-
acter to the end of the string:

```php
echo substr($ourstring, 38);
```

If we just want to print the word “Lazy,” we need to use the optional third parameter to 
specify the length as 4, like this:

```php
echo substr($ourstring, 38, 4);
```

The substr() function can also be used with negative second and third parameters. If you 
specify just parameter one and two and provide a negative number for parameter two, 
substr() counts backward from the end of the string. So, rather than specifying 38 for the 
second parameter, we can use –10, so it takes the last 10 characters from the string. Using 
a negative second parameter and positive third parameter counts backward from the end 
string and then uses a forward length. We can print “Lazy” by counting 10 characters back 
from the end and then taking the next four characters forward:

```php
echo substr($ourstring, -10, 4);
```

Finally, we can use a negative third parameter, too, which also counts back from the end 
of the string. For example, using “-4” as the third parameter means to take everything 
except the last four characters. Confused yet? This code example should make it clear:

```php
echo substr($ourstring, -19, -11);
```
That counts 19 characters backward from the end of the string (which places it at the O in Over) and then copies everything from there until 11 characters before the end of the string. That prints “Over The”. The same thing could be written using –19 and 8, or even 29 and 8—there is more than one way to do it!

Moving on, the strpos() function returns the position of a particular substring inside a string; however, it is most commonly used to answer the question, “Does this string contain a specific substring?” You need to pass it two parameters: a haystack and a needle (yes, that’s a different order from str_replace()!).

In its most basic use, strpos() can find the first instance of “Box” in our phrase, like this:

```php
echo strpos($ourstring, "Box");
```

This outputs 18 because that is where the B in Box starts. If strpos() cannot find the substring in the parent string, it returns false rather than the position. Much more helpful, though, is the ability to check whether a string contains a substring; a first attempt to check whether our string contains the word The might look like this:

```php
<?php
$ourstring = "The Quick Brown Box Jumped Over The Lazy Dog";
if (strpos($ourstring, "The") {
    echo 'Found 'The'!
};
else {
    echo 'The' not found!
};
?>
```

Note that we have temporarily taken out the leading and trailing whitespace from $ourstring and we are using the return value of strpos() for our conditional statement. This reads, “If the string is found, then print a message; if not, print another message.” Or does it?

Run the script, and you will see it print the “not found” message. The reason for this is that strpos() returns false if the substring is not found and otherwise returns the position where it starts. If you recall, any nonzero number equates to true in PHP, which means that 0 equates to false. With that in mind, what is the string index of the first The in our phrase? Because PHP’s strings are zero based and we no longer have the spaces on either side of the string, the The is at position 0, which our conditional statement evaluates to false—hence, the problem.

The solution here is to check for identicality. We know that 0 and false are equal, but they are not identical because 0 is an integer, whereas false is a Boolean. So, we need to rewrite the conditional statement to see whether the return value from strpos() is identical to false. If it is, the substring was not found:

```php
<?php
$ourstring = "The Quick Brown Box Jumped Over The Lazy Dog";
if (strpos($ourstring, "The") !== false) {
```
Arrays

Working with arrays is no easy task, but PHP makes it easier by providing a selection of functions that can sort, shuffle, intersect, and filter them. As with other functions, there is only space here to choose a selection; this is by no means a definitive reference to PHP's array functions.

The easiest function to use is `array_unique()`, which takes an array as its only parameter and returns the same array with all duplicate values removed. Also in the realm of “so easy you do not need a code example” is the `shuffle()` function, which takes an array as its parameter and randomizes the order of its elements. Note that `shuffle()` does not return the randomized array; it uses your parameter as a reference and scrambles it directly. The last too-easy-to-demonstrate function is `in_array()`, which takes a value as its first parameter and an array as its second and returns true if the value is in the array.

With those out of the way, we can focus on the more interesting functions, two of which are `array_keys()` and `array_values()`. They both take an array as their only parameter and return a new array made up of the keys in the array or the values of the array, respectively. The `array_values()` function is an easy way to create a new array of the same data, just without the keys. This is often used if you have numbered your array keys, deleted several elements, and want to reorder it.

The `array_keys()` function creates a new array where the values are the keys from the old array, like this:

```php
<?php
    $myarr = array("foo" => "red", "bar" => "blue", "baz" => "green");
    $mykeys = array_keys($myarr);
    foreach($mykeys as $key => $value) {
        echo "$key = $value
    }
?>
```

That prints “0 = foo”, “1 = bar”, and “2 = baz”.

Several functions are used specifically for array sorting, but only two get much use: `asort()` and `ksort()`, the first of which sorts the array by its values and the second of which sorts the array by its keys. Given the array `$myarr` from the previous example, sorting by the values would produce an array with elements in the order bar/blue, baz/green, and foo/red. Sorting by key would give the elements in the order bar/blue, baz/green, and foo/red. As with the `shuffle()` function, both `asort()` and `ksort()` do their work in place, meaning they return no value, directly altering the parameter you pass.
in. For interest’s sake, you can also use `arsort()` and `krsort()` for reverse value sorting and reverse key sorting, respectively.

This code example reverse sorts the array by value and then prints it as before:

```php
<?php
$myarr = array("foo" => "red", "bar" => "blue", "baz" => "green");
arsort($myarr);
foreach($myarr as $key => $value) {
    echo "$key = $value\n";
}
?>
```

Previously when discussing constants, we mentioned the `extract()` function that converts an array into individual variables; now it is time to start using it for real. You need to provide three variables: the array you want to extract, how you want the variables prefixed, and the prefix you want used. Technically, the last two parameters are optional, but practically you should always use them to properly namespace your variables and keep them organized.

The second parameter must be one of the following:

- `EXTR_OVERWRITE`—If the variable exists already, overwrites it.
- `EXTR_SKIP`—If the variable exists already, skips it and moves on to the next variable.
- `EXTR_PREFIXSAME`—If the variable exists already, uses the prefix specified in the third parameter.
- `EXTR_PREFIXALL`—Prefixes all variables with the prefix in the third parameter, regardless of whether it exists already.
- `EXTR_PREFIXINVALID`—Uses a prefix only if the variable name would be invalid (for example, starting with a number).
- `EXTR_IF EXISTS`—Extracts only variables that already exist. We have never seen this used.

You can also, optionally, use the bitwise OR operator, `|`, to add in `EXTR_REFS` to have `extract()` use references for the extracted variables. In general use, `EXTR_PREFIXALL` is preferred because it guarantees name spacing. `EXTR_REFS` is required only if you need to be able to change the variables and have those changes reflected in the array.

This next script uses `extract()` to convert `$myarr` into individual variables, `$arr_foo`, `$arr_bar`, and `$arr_baz`:

```php
<?php
$myarr = array("foo" => "red", "bar" => "blue", "baz" => "green");
extract($myarr, EXTR_PREFIXALL, 'arr');
?>
```
Note that the array keys are “foo”, “bar”, and “baz” and that the prefix is “arr”, but that the final variables will be $arr_foo, $arr_bar, and $arr_baz. PHP inserts an underscore between the prefix and array key.

Files

As you will have learned from elsewhere in the book, the UNIX philosophy is that everything is a file. In PHP, this is also the case: A selection of basic file functions is suitable for opening and manipulating files, but those same functions can also be used for opening and manipulating network sockets. We cover both here.

Two basic read and write functions for files make performing these basic operations easy. They are file_get_contents(), which takes a filename as its only parameter and returns the file’s contents as a string, and file_put_contents(), which takes a filename as its first parameter and the data to write as its second parameter.

Using these two, we can write a script that reads all the text from one file, filea.txt, and writes it to another, fileb.txt:

```php
<?php
    $text = file_get_contents("filea.txt");
    file_put_contents("fileb.txt", $text);
?>
```

Because PHP enables us to treat network sockets like files, we can also use file_get_contents() to read text from a website, like this:

```php
<?php
    $text = file_get_contents("http://www.slashdot.org");
    file_put_contents("fileb.txt", $text);
?>
```

The problem with using file_get_contents() is that it loads the whole file into memory at once; that’s not practical if you have large files or even smaller files being accessed by many users. An alternative is to load the file piece by piece, which can be accomplished through the following five functions: fopen(), fclose(), fread(), fwrite(), and feof(). The f in those function names stands for file, so they open, close, read from, and write to files and sockets. The last function, feof(), returns true if the end of the file has been reached.

The fopen() function takes a bit of learning to use properly, but on the surface it looks straightforward. Its first parameter is the filename you want to open, which is easy enough. However, the second parameter is where you specify how you want to work with the file, and you should specify one of the following:

- r—Read-only; it overwrites the file.
- r+-Reading and writing; it overwrites the file.
- w—Write-only; it erases the existing contents and overwrites the file.
- w+-Reading and writing; it erases the existing content and overwrites the file.
Basic Functions

- **a**—Write-only; it appends to the file.
- **a+**—Reading and writing; it appends to the file.
- **x**—Write-only, but only if the file does not exist.
- **a+**—Reading and writing, but only if the file does not exist.

Optionally, you can also add b (for example, a+b or rb) to switch to binary mode. This is recommended if you want your scripts and the files they write to work smoothly on other platforms.

When you call `fopen()`, you should store the return value. It is a resource known as a file handle, which the other file functions all need to do their jobs. The `fread()` function, for example, takes the file handle as its first parameter and the number of bytes to read as its second, returning the content in its return value. The `fclose()` function takes the file handle as its only parameter and frees up the file.

So, we can write a simple loop to open a file, read it piece by piece, print the pieces, and then close the handle:

```php
<?php
    $file = fopen("filea.txt", "rb");
    while (!feof($file)) {
        $content = fread($file, 1024);
        echo $content;
    }
    fclose($file);
?>
```

That only leaves the `fwrite()` function, which takes the file handle as its first parameter and the string to write as its second. You can also provide an integer as the third parameter, specifying the number of bytes you want to write of the string, but if you exclude this, `fwrite()` writes the entire string.

If you recall, you can use a as the second parameter to `fopen()` to append data to a file. So, we can combine that with `fwrite()` to have a script that adds a line of text to a file each time it is executed:

```php
<?php
    $file = fopen("filea.txt", "ab");
    fwrite($file, "Testing\n");
    fclose($file);
?>
```

To make that script a little more exciting, we can stir in a new function, `filesize()`, that takes a filename (not a file handle, but an actual filename string) as its only parameter and returns the file's size in bytes. Using that new function brings the script to this:
although PHP automatically cleans up file handles for you, it is still best to use \texttt{fclose()} yourself so you are always in control.

\section*{Miscellaneous}

Several functions do not fall under the other categories and so are covered here. The first one is \texttt{isset()}, which takes one or more variables as its parameters and returns \texttt{true} if they have been set. It is important to note that a variable with a value set to something that would be evaluated to \texttt{false}—such as \texttt{0} or an empty string—still returns \texttt{true} from \texttt{isset()} because it does not check the value of the variable. It merely checks that it is set; hence, the name.

The \texttt{unset()} function also takes one or more variables as its parameters, simply deleting the variable and freeing up the memory. With these two, we can write a script that checks for the existence of a variable and, if it exists, deletes it (see Listing 29.5).

\begin{lstlisting}[language=PHP]<?php
$name = "Ildiko";
if (isset($name)) {
    echo "Name was set to $name
";
    unset($name);
} else {
    echo "Name was not set";
}

if (isset($name)) {
    echo "Name was set to $name
";
    unset($name);
} else {
    echo "Name was not set";
}
?>
\end{lstlisting}

That script runs the same \texttt{isset()} check twice, but \texttt{unset()}s the variable after the first check. As such, it prints “Name was set to Ildiko” and then “Name was not set”.

Perhaps the most frequently used function in PHP is \texttt{exit}, although purists will tell you that it is in fact a language construct rather than a function. \texttt{exit} terminates the processing of the script as soon as it is executed, meaning subsequent lines of code are not
executed. That is really all there is to it; it barely deserves an example, but here is one just to make sure:

```php
<?php
    exit;
    echo "Exit is a language construct!\n";
?>
```

That script prints nothing because the `exit` comes before the `echo`.

One function we can guarantee you will use a lot is `var_dump()`, which dumps out information about a variable, including its value, to the screen. This is invaluable for arrays because it prints every value and, if one or more of the elements is an array, it prints all the elements from those, and so on. To use this function, just pass it a variable as its only parameter:

```php
<?php
    $drones = array("Graham", "Julian", "Nick", "Paul");
    var_dump($drones);
?>
```

The output from that script looks like this:

```
array(4) {
    [0]=>
        string(6) "Graham"
    [1]=>
        string(6) "Julian"
    [2]=>
        string(4) "Nick"
    [3]=>
        string(4) "Paul"
}
```

The `var_dump()` function sees a lot of use as a basic debugging technique because it is the easiest way to print variable data to the screen to verify it.

Finally, we briefly discuss regular expressions; with the emphasis on *briefly* because regular expression syntax is covered elsewhere in this book and the only unique thing relevant to PHP are the functions you will use to run the expressions. You have the choice of either Perl-Compatible Regular Expressions (PCRE) or POSIX Extended regular expressions, but there really is little to choose between them in terms of functionality offered. For this chapter, we use the PCRE expressions because, to the best of our knowledge, they see more use by other PHP programmers.

The main PCRE functions are `preg_match()`, `preg_match_all()`, `preg_replace()`, and `preg_split()`. We will start with `preg_match()` because it provides the most basic functionality by returning `true` if one string matches a regular expression. The first parameter
to preg_match() is the regular expression you want to search for, and the second is the string to match. So, if we wanted to check whether a string had the word *Best*, *Test*, *rest*, *zest*, or any other word containing *est* preceded by any letter of either case, we could use this PHP code:

```php
$result = preg_match("/[A-Za-z]est/", "This is a test");
```

Because the test string matches the expression, $result is set to 1 (true). If you change the string to a nonmatching result, you get 0 as the return value.

The next function is preg_match_all(), which gives you an array of all the matches it found. However, to be most useful, it takes the array to fill with matches as a by-reference parameter and saves its return value for the number of matches that were found.

We suggest you use preg_match_all() and var_dump() to get a feel for how the function works. This example is a good place to start:

```php
<?php
    $string = "This is the best test in the west";
    $result = preg_match_all("/[A-Za-z]est/", $string, $matches);
    var_dump($matches);
?>
```

That outputs the following:

```
array(1) {
    [0]=>
    array(3) {
        [0]=>
        string(4) "best"
        [1]=>
        string(4) "test"
        [2]=>
        string(4) "west"
    }
}
```

If you notice, the $matches array is actually multidimensional in that it contains one element, which itself is an array containing all the matches to our regular expression. The reason for this is because our expression has no *subexpressions*, meaning no independent matches using parentheses. If we had subexpressions, each would have its own element in the $matches array containing its own array of matches.

Moving on, preg_replace() is used to change all substrings that match a regular expression into something else. The basic manner of using this is quite easy: You search for something with a regular expression and provide a replacement for it. However, a more useful variant is *backreferencing*, using the match as part of the replacement. For our example, we will imagine you have written a tutorial on PHP but want to process the text so each reference to a function is followed by a link to the PHP manual.
PHP manual page URLs take the form www.php.net/<somefunc>—for example, www.php.net/preg_replace. The string we need to match is a function name, which is a string of alphabetic characters, potentially also mixed with numbers and underscores and terminated with two parentheses, (). As a replacement, we will use the match we found, surrounded in HTML emphasis tags (<em></em>), and then with a link to the relevant PHP manual page. Here is how that looks in code:

```php
<?php
  $regex = "/(\[A-Za-z0-9_\]*)\(\)/";
  $replace = "<em>$1</em> (<a href="http://www.php.net/$1">manual</A>)";
  $haystack = "File_get_contents()is easier than using fopen().";
  $result = preg_replace($regex, $replace, $haystack);
  echo $result;
?>
```

The $1 is our backreference; it will be substituted with the results from the first subexpression. The way we have written the regular expression is very exact. The [A-Za-z0-9_] part, which matches the function name, is marked as a subexpression. After that is \(\), which means the exact symbols (and), not the regular expression meanings of them, which means that $1 in the replacement will contain fopen rather than fopen(), which is how it should be. Of course, anything that is not backreferenced in the replacement is removed, so we have to put the () after the first $1 (not in the hyperlink) to repair the function name.

After all that work, the output is perfect:

```html
```

### Handling HTML Forms

Given that PHPs primary role is handling web pages, you might wonder why this section has been left so late in the chapter. It is because handling HTML forms is so central to PHP that it is essentially automatic.

Consider this form:

```html
<form method="POST" action="thispage.php">
  User ID: <input type="text" name="UserID" /><br />
  Password: <input type="password" name="Password" /><br />
  <input type="submit" />
</form>
```

When a visitor clicks Submit, thispage.php is called again and this time PHP has the variables available to it inside the $_REQUEST array. Given that script, if the user enters 12345 and frosties as her user ID and password, PHP provides you with
$_REQUEST['UserID'] set to 12345 and $_REQUEST['Password'] set to frosties. Note that it is important that you use HTTP post unless you specifically want GET. POST enables you to send a great deal more data and stops people from tampering with your URL to try to find holes in your script.

Is that it? Well, almost. That tells you how to retrieve user data, but you should be sure to sanitize it so users do not try to sneak HTML or JavaScript into your database as something you think is innocuous. PHP gives you the strip_tags() function for this purpose. It takes a string and returns the same string with all HTML tags removed.

**Databases**

The ease with which PHP can be used to create dynamic, database-driven websites is for the key reason to use it for many people. The stock build of PHP comes with support for MySQL, PostgreSQL, SQLite, Oracle, Microsoft SQL Server, ODBC, plus several other popular databases, so you are sure to find something to work with your data.

If you want to, you can learn all the individual functions for connecting to and manipulating each database PHP supports, but a much smarter, or at least easier, idea is to use PEAR::DB. PEAR::DB is an abstraction layer over the databases that PHP supports, which means you write your code once, and—with the smallest of changes—it will work on every database server.

PEAR is the script repository for PHP and contains numerous tools and prewritten solutions for common problems. PEAR::DB is perhaps the most popular part of the PEAR project, but it is worth checking out the PEAR site to see whether anything else catches your eye.

To get basic use out of PEAR::DB, you need to learn how to connect to a database, run a SQL query, and work with the results. This is not a SQL tutorial, so we have assumed you are already familiar with the language. For the sake of this tutorial, we have also assumed you are working with a database called **dentists** and a table called **patients** that contains the following fields:

- **ID**—The primary key, auto-incrementing integer for storing a number unique to each patient
- **Name**—A varchar(255) field for storing a patient name
- **Age**—Integer
- **Sex**—1 for male, 2 for female
- **Occupation**—A varchar(255) field for storing a patient occupation

Also for the sake of this tutorial, we will use a database server on IP address 10.0.0.1, running MySQL, with username ubuntu and password alm65z. You will need to replace these details with your own—use localhost for connecting to the local server.
The first step to using PEAR::DB is to include the standard PEAR::DB file, DB.php. Your PHP will be configured to look inside the PEAR directory for include() files, so you do not need to provide any directory information.

PEAR::DB is object oriented, and you specify your connection details at the same time as you create the initial DB object. This is done using a URL-like system that specifies the database server type, username, password, server, and database name all in one. After you have specified the database server here, everything else is abstracted, meaning you only need to change the connection line to port your code to another database server.

This first script connects to our server and prints a status message (see Listing 29.6).

LISTING 29.6 Connecting to a Database Through PEAR::~DB

```php
<?php
    include("DB.php");
    $dsn = "mysql://ubuntu:alm65z@10.0.0.1/dentists";
    $conn = DB::connect($dsn);
    if (DB::isError($conn)) {
        echo $conn->getMessage() . "\n";
    } else {
        echo "Connected successfully!\n";
    }
?>
```

You should be able to see how the connection string breaks down. It is server name first, then a username and password separated by a colon, then an @ symbol followed by the IP address to which to connect, and then a slash and the database name. Notice how the call to connect is DB::connect(), which calls PEAR::DB directly and returns a database connection object for storage in $conn. The variable name $dsn was used for the connection details because it is a common acronym standing for data source name.

If DB::connect() successfully connects to a server, it returns a database object we can use to run SQL queries. If not, we get an error returned that we can query using functions such as getMessage(). In the previous script, we print the error message if we fail to connect, but we also just print a message if we succeed. Next, we will change that so we run an SQL query if we have a connection.

Running SQL queries is done through the query() function of our database connection, passing in the SQL we want to execute. This then returns a query result that can be used to get the data. This query result can be thought of as a multidimensional array because it has many rows of data, each with many columns of attributes. This is extracted using the fetchInto() function, which loops through the query result converting one row of data into an array that it sends back as its return value. You need to pass in two parameters to fetchInto() specifying where the data should be stored and how you want it stored.
Unless you have unusual needs, specifying `DB_FETCHMODE_ASSOC` for the second parameter is a smart move.

Listing 29.7 shows the new script.

LISTING 29.7 Running a Query Through PEAR::DB

```php
<?php
    include("DB.php");
    $dsn = "mysql://ubuntu:alm65z@10.0.0.1/dentists";
    $conn = DB::connect($dsn);
    if (DB::isError($conn)) {
        echo $conn->getMessage() . "\n";
    } else {
        echo "Connected successfully!". "\n";
        $result = $conn->query("SELECT ID, Name FROM patients;");
        while ($result->fetchInto($row, DB_FETCHMODE_ASSOC)) {
            extract($row, EXTR_PREFIX_ALL, 'pat');
            echo "$pat_ID is $pat_Name\n";
        }
    }
?>
```

The first half is identical to the previous script, with all the new action happening if we get a successful connection.

Going along with the saying “never leave to PHP what you can clean up yourself,” the current script has problems. We do not clean up the query result, and we do not close the database connection. If this code were being used in a longer script that ran for several minutes, this would be a huge waste of resources. Fortunately, we can free up the memory associated with these two by calling `$result->free()` and `$conn->disconnect()`. If we add those two function calls to the end of the script, it will be complete.

There are quite a few good PHP magazines around, but *PHP Architect* probably leads the way. It posts some of its articles online for free, and its forums are good, too.

If you’re looking to learn C or C++ programming, this part of the book isn’t the right place to start—unlike Perl, Python, PHP, or even C#, it takes more than a little dabbling to produce something productive with C, so this chapter is primarily focused on the tools Ubuntu offers you as a C or C++ programmer.

Whether you’re looking to compile your own code or someone else’s, the GNU Compiler Collection (gcc) is there to help—it understands C, C++, Fortran, Pascal, and dozens of other popular languages, which means you can try your hand at whatever interests you. Ubuntu also ships with hundreds of libraries you can link to, from the GUI toolkits behind GNOME and KDE to XML parsing and game coding. Some use C, others C++, and still others offer support for both, meaning you can choose what you’re most comfortable with.

**Programming in C with Linux**

C is the programming language most frequently associated with UNIX-like operating systems such as Linux or BSD. Since the 1970s, the bulk of the UNIX operating system and its applications have been written in C. Because the C language doesn’t directly rely on any specific hardware architecture, UNIX was one of the first portable operating systems. In other words, the majority of the code that makes up UNIX doesn’t know and doesn’t care which computer it is actually running on. Machine-specific features are isolated in a few modules within the UNIX kernel, which makes it easy for you to modify them when you are porting to different hardware architectures.
C is a compiled language, which means that your C source code is first analyzed by the preprocessor and then translated into assembly language first and then into machine instructions that are appropriate to the target CPU. An assembler then creates a binary, or object, a file from the machine instructions. Finally, the object file is linked to any required external software support by the linker. A C program is stored in a text file that ends with a .c extension and always contains at least one routine, or function, such as main(), unless the file is an include file (with a .h extension, also known as a header file) containing shared variable definitions or other data or declarations. Functions are the commands that perform each step of the task that the C program was written to accomplish.

**NOTE**
The Linux kernel is mostly written in C, which is why Linux works with so many different CPUs. To learn more about building the Linux kernel from source, see Chapter 36, “Kernel and Module Management.”

C++ is an object-oriented extension to C. Because C++ is a superset of C, C++ compilers compile C programs correctly, and it is possible to write non–object-oriented code in C++. The reverse is not true: C compilers cannot compile C++ code.

C++ extends the capabilities of C by providing the necessary features for object-oriented design and code. C++ also provides some features, such as the capability to associate functions with data structures that do not require the use of class-based object-oriented techniques. For these reasons, the C++ language enables existing UNIX programs to migrate toward the adoption of object orientation over time.

Support for C++ programming is provided by gcc, which you run with the name g++ when you are compiling C++ code.

**Using the C Programming Project Management Tools Provided with Ubuntu**

Ubuntu is replete with tools that make your life as a C/C++ programmer easier. There are tools to create programs (editors), compile programs (gcc), create libraries (ar), control the source (Git, Mercurial, Subversion), automate builds (make), debug programs (gdb and ddd), and determine where inefficiencies lie (gprof).

The following sections introduce some of the programming and project management tools included with Ubuntu. If you have some previous UNIX experience, you will be familiar with most of these programs because they are traditional complements to a programmer's suite of software.
Building Programs with make

You use the make command to automatically build and install a C program, and for that use it is an easy tool. If you want to create your own automated builds, however, you need to learn the special syntax that make uses; the following sections walk you through a basic make setup.

Using Makefiles

The make command automatically builds and updates applications by using a makefile. A makefile is a text file that contains instructions about which options to pass on to the compiler preprocessor, the compiler, the assembler, and the linker. The makefile also specifies, among other things, which source code files have to be compiled (and the compiler command line) for a particular code module and which code modules are needed to build the program—a mechanism called dependency checking.

The beauty of the make command is its flexibility. You can use make with a simple makefile, or you can write complex makefiles that contain numerous macros, rules, or commands that work in a single directory or traverse your file system recursively to build programs, update your system, and even function as document management systems. The make command works with nearly any program, including text processing systems such as TeX.

You could use make to compile, build, and install a software package, using a simple command like this:

```
matthew@seymour:~$ sudo make install
```

You can use the default makefile (usually called Makefile, with a capital M), or you can use make's -f option to specify any makefile, such as MyMakeFile, like this:

```
matthew@seymour:~$ sudo make -f MyMakeFile
```

Other options might be available, depending on the contents of your makefile. You may have a source file named hi.c and just run make hi, where make figures out what to do automatically to build the final executable. See make's built in rules with make -p.

Using Macros and Makefile Targets

Using make with macros can make a program portable. Macros allow users of other operating systems to easily configure a program build by specifying local values, such as the names and locations, or pathnames, of any required software tools. In the following example, macros define the name of the compiler (CC), the installer program (INS), where the program should be installed (INSDIR), where the linker should look for required libraries (LIBDIR), the names of required libraries (LIBS), a source code file (SRC), the intermediate object code file (OBJS), and the name of the final program (PROG):

```
# a sample makefile for a skeleton program
CC= gcc
INS= install
```

Download from www.eBookTM.com
INSDIR = /usr/local/bin
LIBDIR= -L/usr/X11R6/lib
LIBS= -lXm -lSM -lICE -lXt -lX11
SRC= skel.c
OBJS= skel.o
PROG= skel

skel:  ${OBJS}
       ${CC} -o ${PROG} ${SRC} ${LIBDIR} ${LIBS}

install: ${PROG}
       ${INS} -g root -o root ${PROG} ${INSDIR}

NOTE
The indented lines in the previous example are indented with tabs, not spaces. This is important to remember! It is difficult for a person to see the difference, but make can tell. If make reports confusing errors when you first start building programs under Linux, check your project's makefile for the use of tabs and other proper formatting.

Using the makefile from the preceding example, you can build a program like this:
matthew@seymour:~$ sudo make

To build a specified component of a makefile, you can use a target definition on the command line. To build just the program, you use make with the skel target, like this:
matthew@seymour:~$ sudo make skel

If you make any changes to any element of a target object, such as a source code file, make rebuilds the target automatically. This feature is part of the convenience of using make to manage a development project. To build and install a program in one step, you can specify the target of install like this:
matthew@seymour:~$ sudo make install

Larger software projects might have a number of traditional targets in the makefile, such as the following:

- test—To run specific tests on the final software
- man—To process an include or a troff document with the man macros
- clean—To delete any remaining object files
- archive—To clean up, archive, and compress the entire source code tree
- bugreport—To automatically collect and then mail a copy of the build or error logs
Large applications can require hundreds of source code files. Compiling and linking these applications can be a complex and error-prone task. The `make` utility helps you organize the process of building the executable form of a complex application from many source files.

**Using the autoconf Utility to Configure Code**

The `make` command is only one of several programming automation utilities included with Ubuntu. There are others, such as `pmake` (which causes a parallel `make`), `imake` (which is a dependency-driven makefile generator that is used for building X11 clients), `automake`, and one of the newer tools, `autoconf`, which builds shell scripts that can be used to configure program source code packages.

Building many software packages for Linux that are distributed in source form requires the use of GNU’s `autoconf` utility. This program builds an executable shell script named `configure` that, when executed, automatically examines and tailors a client’s build from source according to software resources, or dependencies (such as programming tools, libraries, and associated utilities) that are installed on the target host (your Linux system).

Many Linux commands and graphical clients for X downloaded in source code form include `configure` scripts. To configure the source package, build the software, and then install the new program, the root user might use the script like this (after uncompressing the source and navigating into the resulting build directory):

```
matthew@seymour:~$ ./configure ; make ; sudo make install
```

The `autoconf` program uses a file named `configure.in` that contains a basic ruleset, or set of macros. The `configure.in` file is created with the `autoscan` command. Building a properly executing `configure` script also requires a template for the makefile, named `Makefile.in`. Although creating the dependency-checking `configure` script can be done manually, you can easily overcome any complex dependencies by using a graphical project development tool such as KDES KDevelop or GNOME’s Glade. (See the “Graphical Development Tools” section, later in this chapter, for more information.)

**Managing Software Projects with Subversion**

Although `make` can be used to manage a software project, larger software projects require document management, source code controls, security, and revision tracking as the source code goes through a series of changes during its development. Subversion provides source code version control utilities for this kind of large software project management.

The Subversion system is used to track changes to multiple versions of files, and it can be used to backtrack or branch off versions of documents inside the scope of a project. It can also be used to prevent or resolve conflicting entries or changes made to source code files by multiple developers. Source code control with Subversion requires the use of at least the following five command options on the `svn` command line:

- **checkout**—Checks out revisions
- **update**—Updates your sources with changes made by other developers
add—Adds new files to the repository

delete—Eliminates files from the repository

commit—Publishes changes to other repository developers

Note that some of these commands require you to use additional fields, such as the names of files. With the commit command, you should always try to pass the -m parameter (lets you provide a message describing the change) followed by some information about your changes. For example:

```
matthew@seymour:~$ svn commit -m "This fixes bug 204982."
```

One of the most impressive features of Subversion is its capability to work offline—any local Subversion checkout automatically has a .svn directory hidden in there, which contains copies of all checked-out files. Thanks to this, you can check your current files against the ones you checked out without having to contact the server—it all runs locally.

### Debugging Tools

Debugging is both a science and an art. Sometimes, the simplest tool—the code listing—is the best debugging tool. At other times, however, you need to use other debugging tools. Three of these tools are splint, gprof, and gdb.

#### Using splint to Check Source Code

The splint command is similar to the traditional UNIX lint command: It statically examines source code for possible problems, and it also has many additional features. Even if your C code meets the standards for C and compiles cleanly, it might still contain errors. splint performs many types of checks and can provide extensive error information. For example, this simple program might compile cleanly and even run:

```
matthew@seymour:~$ gcc -o tux tux.c
matthew@seymour:~$ ./tux
```

But the splint command might point out some serious problems with the source:

```
matthew@seymour:~$ splint tux.c
Splint 3.1.2 — 29 Apr 2009

tux.c: (in function main)
tux.c:2:19: Return value (type int) ignored: putchar(t[++j] -...
    Result returned by function call is not used. If this is intended, can cast result to (void) to eliminate message. (Use -retvalint to inhibit warning)
Finished checking — 1 code warning
```

You can use the splint commands -strict option, like this, to get a more verbose report:

```
matthew@seymour:~$ splint -strict tux.c
```
GCC also supports diagnostics through the use of extensive warnings (through the `-Wall` and `-pedantic` options):

```
matthew@seymour:-$ gcc -Wall tux.c
```

```
tux.c:1: warning: return type defaults to 'int'
tux.c: In function 'main':
tux.c:2: warning: implicit declaration of function 'putchar'
```

### Using gprof to Track Function Time

You use the `gprof` (profile) command to study how a program is spending its time. If a program is compiled and linked with `-p` as a flag, a `mon.out` file is created when it executes, with data on how often each function is called and how much time is spent in each function. `gprof` parses and displays this data. An analysis of the output generated by `gprof` helps you determine where performance bottlenecks occur. Using an optimizing compiler can speed up a program, but taking the time to use `gprof`'s analysis and revising bottleneck functions significantly improves program performance.

### Doing Symbolic Debugging with gdb

The `gdb` tool is a symbolic debugger. When a program is compiled with the `-g` flag, the symbol tables are retained and a symbolic debugger can be used to track program bugs. The basic technique is to invoke `gdb` after a `core dump` (a file containing a snapshot of the memory used by a program that has crashed) and get a stack trace. The stack trace indicates the source line where the core dump occurred and the functions that were called to reach that line. Often, this is enough to identify a problem. It isn't the limit of `gdb`, though.

`gdb` also provides an environment for debugging programs interactively. Invoking `gdb` with a program enables you to set breakpoints, examine the values of variables, and monitor variables. If you suspect a problem near a line of code, you can set a breakpoint at that line and run `gdb`. When the line is reached, execution is interrupted. You can check variable values, examine the stack trace, and observe the program's environment. You can single-step through the program to check values. You can resume execution at any point. By using breakpoints, you can discover many bugs in code.

A graphical X Window interface to `gdb` is called the Data Display Debugger, or ddd.

### Using the GNU C Compiler

If you elected to install the development tools package when you installed Ubuntu (or perhaps later on, using synaptic), you should have the GNU C compiler (`gcc`). Many different options are available for the GNU C compiler, and many of them are similar to those of the C and C++ compilers that are available on other UNIX systems. Look at the man page or information file for `gcc` for a full list of options and descriptions.
When you build a C program using gcc, the compilation process takes place in several steps:

1. First, the C preprocessor parses the file. To do so, it sequentially reads the lines, includes header files, and performs macro replacement.

2. The compiler parses the modified code to determine whether the correct syntax is used. In the process, it builds a symbol table and creates an intermediate object format. Most symbols have specific memory addresses assigned, although symbols defined in other modules, such as external variables, do not.

3. The last compilation stage, linking, ties together different files and libraries and then links the files by resolving the symbols that had not previously been resolved.

**NOTE**

Most C programs compile with a C++ compiler if you follow strict ANSI rules. For example, you can compile the standard hello.c program (everyone's first program) with the GNU C++ compiler. Typically, you name the file something like hello.cc, hello.C, hello.c++, or hello.cxx. The GNU C++ compiler accepts any of these names.

**Graphical Development Tools**

Ubuntu includes a number of graphical prototyping and development environments for use during X sessions. If you want to build client software for KDE or GNOME, you might find the KDevelop, Qt Designer, and Glade programs extremely helpful. You can use each of these programs to build graphical frameworks for interactive windowing clients, and you can use each of them to automatically generate the necessary skeleton of code needed to support a custom interface for your program.

**Using the KDevelop Client**

You can launch the KDevelop client (shown in Figure 30.1) from the application’s menu, or from the command line of a terminal window, like this:

```
matthew@seymour:~$ kdevelop &
```

After you press Enter, the KDevelop Setup Wizard runs, and you are taken through several short wizard dialogs that set up and ensure a stable build environment. You must then run kdevelop again (either from the command line or by clicking its menu item under the desktop panel's Programming menu). You will then see the main KDevelop window and can start your project by selecting KDevelop’s Project menu and clicking the New menu item.

You can begin building your project by stepping through the wizard dialogs. When you click the Create button, KDevelop automatically generates all the files that are normally found in a KDE client source directory (including the configure script, which checks
dependencies and builds the client's makefile). To test your client, you can either first click the Build menu's Make menu item (or press F8) or just click the Execute menu item (or press F9), and the client is built automatically. You can use KDevelop to create KDE clients, plug-ins for the Konqueror browser, KDE kicker panel applets, KDE desktop themes, Qt library–based clients, and even programs for GNOME.

**FIGURE 30.1** KDE's KDevelop is a rapid prototyping and client-building tool for use with Linux.

---

**The Glade Client for Developing in GNOME**

If you prefer to use GNOME and its development tools, the Glade GTK+ GUI builder can help you save time and effort when building a basic skeleton for a program. You launch Glade from the desktop panel's Programming menu.

When you launch Glade, a directory named Projects is created in your home directory, and you see a main window, along with two floating Palette and Properties windows (see Figure 30.2, which shows a basic GNOME client with a calendar widget added to its main window). You can use Glade's File menu to save the blank project and then start building your client by clicking and adding user interface elements from the Palette window. For example, you can first click the Palette window's Gnome button and then click to create
your new client’s main window. A window with a menu and a toolbar appears—the basic framework for a new GNOME client!

FIGURE 30.2 You can use the GNOME Glade client to build and preview a graphical interface for a custom GNOME program.

Although Microsoft intended it for Windows, Microsoft’s .NET platform has grown to encompass many other operating systems. No, this isn’t a rare sign of Microsoft letting customers choose which OS is best for them—instead, the spread of .NET is because of the Mono project, which is a free re-implementation of .NET available under the a GPL license.

Because of the potential for patent complications, it took most distros a long time to incorporate Mono, but it’s here now and works just fine. What’s more, Mono supports both C# and Visual Basic .NET, as well as the complete .NET 1.0 and 1.1 Frameworks (and much of the 2.0 Framework, too), making it quick to learn and productive to use.

Why Use Mono?

Linux already has numerous programming languages available to it, so why bother with Mono and .NET? Here are my top five reasons:

- .NET is “compile once, run anywhere”; that means you can compile your code on Linux and run it on Windows, or the reverse.
- Mono supports C#, which is a C-like language with many improvements to help make it object-oriented and easier to use.
- .NET includes automatic garbage collection to remove the possibility of memory leaks.
.NET uses comes with built-in security checks to ensure that buffer overflows and many types of exploits are a thing of the past.

Mono uses a high-performance just-in-time compiler to optimize your code for the platform on which it’s running. This lets you compile it on a 32-bit machine, then run it on a 64-bit machine and have the code dynamically re-compiled for maximum 64-bit performance.

At this point, Mono is probably starting to sound like Java, and indeed it shares several properties with it. However, Mono has the following improvements:

- The C# language corrects many of the irritations in Java, while keeping its garbage collection.
- .NET is designed to let you compile multiple languages down to the same bytecode, including C#, Visual Basic .NET, and many others.
- Mono even has a special project (known as “IKVM”) that compiles Java source code down to .NET code that can be run on Mono.
- Mono is completely open source!

Whether you’re looking to create command-line programs, graphical user interface apps, or even web pages, Mono has all the power and functionality you need.

Mono is made up of several components including a C# compiler, the Mono Runtime, the Base Class Library and the Mono Class Library.

The C# compiler includes all of the features to compile C# 1.0, 2.0, and 3.0 (ECMA) code. Mono 2.6, which is installed by default in Ubuntu 10.10, includes a preview implementation of C# 4.0, which is expected to be complete in Mono 2.8. The compiler is able to compile itself, is fast, and includes a test suite. The C# compiler gives you your pick of several services that applications may consume:

- **mcs**—References the 1.0-profile libraries and supports C# 1.0 and C# 3.0, minus generics and any features that depend on generics and is called mono-cms in the Ubuntu software repositories.
- **gmcs**—References the 2.0-profile libraries and supports the full C# 3.0 language and is called mono-gcms in the Ubuntu software repositories and is installed by default in Ubuntu 10.10.
- **smcs**—References the 2.1-profile libraries, supports the full C# 3.0 language, and is used for creating Moonlight (the Mono version of Silverlight) applications. It is not available in the Ubuntu software repositories.
- **dmcs**—Targets the C# 4.0 language and is not available in the Ubuntu software repositories.

The first three in that list are all the same compiler, but with different default settings. The last one listed is new and will become the default in Mono 2.8.

The Mono Runtime uses the ECMA Common Language Infrastructure (CIL). This is a runtime similar to the Java Virtual Machine. It provides a Just In Time (JIT) compiler, an
Ahead Of Time (AOT) compiler, a library loader, a garbage collector, a threading system, and interoperability functionality. The execution engine, mono, can be used as a stand-alone process. By itself it runs as a JIT or AOT code generator. With —full-aot, it can run in fully static mode with no JIT involvement. You can reuse your existing C and C++ code and extend it with Mono either with scripting or by embedding Mono into applications.

The Mono Base Class Library provides a set of foundational classes that are compatible with Microsoft’s .Net Framework. It is extended by the Mono Class Library that provides additional functions that are especially useful when building Linux applications, such as classes for Gtk+, LDAP, and POSIX.

Mono runs on many platforms, not just Linux. It is designed as a free-software implementation of Microsoft’s C# and can also run on Windows, Mac OSX, BSD, Solaris, Nintendo Wii, Sony PlayStation 3, and the Apple iPhone. It will work on many different types of processors, including the common x86 and x86-64 that Ubuntu targets, and also others like PowerPC, SPARC, ARM, Alpha, and more. The Common Language Runtime (CLR) that comes with Mono allows you to choose other programming languages, write your code using them, and then run the programs in Mono (see mono-project.com/Languages).

**MonoDevelop**

- Mono should already be installed on your system, however it is installed only for end users rather than for developers—you need to install a couple more packages to make it usable for programming. Install `mono-complete` and `monodevelop` from the Ubuntu repositories.

- These give you the basics to do Mono development.

If you want to do other exciting things with Mono, lots of Mono-enabled libraries are available. Use Synaptic at System, Administration, Synaptic Package Manager to search the Ubuntu software repositories for “sharp” to bring up the list of .NET-enabled libraries that you can use with Mono—the suffix is used because C# is the most popular .NET language, indeed the flagship language in the .NET fleet, written especially for .NET. In this list you’ll see things such as gnome-sharp2 and gtk-sharp2—we recommend you at least install the gtk-sharp2 libraries because these are used to create graphical user interfaces for Mono.

Open MonoDevelop from the menu at Applications, Programming, MonoDevelop.

**TIP**

You don’t have to use MonoDevelop to write your code, but it helps—syntax highlighting, code completion, and drag-and-drop GUI designers are just a few of its features.

When MonoDevelop has loaded, open File, New, Solution. From the left of the window that appears, choose C#, then Console Project. Give it a name and choose a location to save it, as in Figure 31.1. When you’re ready, click Forward.
This is a simple command-line project. For our example, select Unix Integration as the only feature to include in Figure 31.2 and click OK. Notice that this generates a launch script by default and allows you to choose to create a .desktop file if desired. You can also create packaging as an archive of binaries or a tarball and enable support for GTK#. We don’t need either of these for our example.

The default Console Project template creates a program that prints a simple message to the command line: the oh-so-traditional “Hello World!” Click Build, Build HelloWorld (or F7) to build the project (Figure 31.3). Click Run, Run (or Ctrl+F5) to run the program. A terminal window will appear to show you the output of your program as shown in Figure 31.4.

You can also run and debug at the same time using Run, Debug (or F5). If there are errors in the program code, you will be notified, as seen in Figure 31.5. I created a simple error by removing a letter from the end of a word. If there are no errors, the program will run as it did when we used Run, Run previously.

The Structure of a C# Program

As you can guess from its name, C# draws very heavily on C and C++ for its syntax, but it borrows several ideas from other languages that its creator, Hejlsberg, had experience with like Java, Turbo Pascal, Delphi, Python, Icon, Smalltalk, and Modula-2 and 3. C# is object-oriented. In C# you define a class, which is then instantiated by calling its constructor.
FIGURE 31.2  Choose the Project Features you want to enable in your project.

FIGURE 31.3  MonoDevelop with HelloWorld loaded, showing a successful build notice at the bottom.
Main() is the default entry point for an executable assembly in MonoDevelop and Visual Studio .NET. To be able to draw on some of the .NET framework’s many libraries, you need to add using statements at the top of your files—by default only using System; is included, enabling you to access the console to write your Hello World! message.

If you have experience with C or C++, you will notice that there are no header files in C#: your class definition and its implementation are all in the same file. You might also have noticed that the Main() method accepts the parameter "string[] args", which means we will be passing arguments from the command line and is C#-speak for “an array of strings.” C never had a native “string” data type, whereas C++ acquired it rather late in the game, and so both languages tend to use the antiquated char* data type to point to a string of characters. In C#, "string" is a data type all its own, and comes with built-in functionality such as the capability to replace substrings, the capability to trim off white-space, and the capability to convert itself to upper- or lowercase if you want it to. Strings are also Unicode friendly out of the box in .NET, so that’s one fewer thing for you to worry about.

The final thing you might have noticed—at least, if you had looked in the directory where MonoDevelop placed your compiled program (usually /path/to/your/project/bin/Debug)—is that Mono uses the Windows-like .exe file extension for its programs. Because Mono aims to be 100 percent compatible with Microsoft .NET, which means you can take your Hello World program and run it unmodified on a Windows machine and have the same message printed out.

**Printing Out the Parameters**

We’re going to expand your little program by having it print out all the parameters passed to it, one per line. In C# this is—amazingly—just one line of code. Add this just after the existing Console.WriteLine() line in your program:

```csharp
foreach (string arg in args) Console.WriteLine(arg);
```
The `foreach` keyword is a special kind of loop designed to iterate over any collection, in this case an array. The `for` loop exists in C#, and lets you loop a certain number of times; the `while` loop exists too, and lets you loop continuously until a conditional is no longer true or a break statement is encountered—the conditional controls the loop and a break statement will allow an exit if desired or included. But the `foreach` loop is designed to loop over a collection from the start to the end. You get each value as a variable of any type you want—the preceding code says `string arg in args`, which means “for each array element in args, give it to me as the variable `arg` of type `string`.” Because `args` is already an array of strings, no datatype conversion will take place here—but it could if you wanted to convert classes or do anything of the like. One reason you might use a `for` loop over a `foreach` loop is if you need to determine an index into a collection, as in finding a minimum or maximum value. There is no index available for the current iteration in a `foreach` loop, much like it is not available in a `while` loop.

After you have each individual argument, call `WriteLine()` to print it out. This works whether there’s one argument or one hundred arguments—or even if there are no arguments at all (in which case the loop doesn’t execute at all).

### Creating Your Own Variables

You can have anonymous variable types and “var” variable declarations in C#. You can also specify variable types with great precision. Most of the time you can use `int` and leave C# to work out the details. Let’s modify our program to accept two parameters, add them together as numbers, and then print the result. This gives you a chance to see variable definitions, conversion, and mathematics, all in one. Edit the `Main()` method to look like this:

```csharp
using System;

namespace AddNumbers {
    class MainClass {
        public static void Main (string[] args) {
            int num1 = int.Parse(args[0]);
            int num2 = int.Parse(args[1]);
            Console.WriteLine("Sum of two parameters is: " + (num1 + num2));
        }
    }
}
```

Run this new code using Run, Run With, Custom Parameter. As you can see, each variable is declared with a type (`int`) and a name (`num1` and `num2`), so that C# knows how to handle them. The `args` array contains strings, so we convert the strings to integers with the `int.Parse()` method. Finally, the actual addition of the two strings is done at the end of the method, while they are being printed out. Note how C# is clever enough to have
integer + integer be added together (in the case of num + num2), whereas string +
integer attaches the integer to the end of the string (in the case of "Sum of two parame-
ters is:" + the result of num1 + num2). This isn’t by accident: C# tries to convert
data types cleverly, and warns you only if it can’t convert a data type without losing some
data. For example, if you try to treat a 64-bit integer as a 32-bit integer, it warns you
because you might be throwing a lot of data away. You can use int.TryParse() to attempt
parsing conditionally, and it would also return a boolean response indicating success or
failure. In addition, you can also use checked conversions to perform operations and have
the compiler verify that they do not cause overflow (essentially meaning the variable
could not represent the value).

Adding Some Error Checking

Right now your program crashes in a nasty way if users don’t provide at least two param-
ters. The reason for this is that we use arg[0] and arg[1] (the first and second parameters
passed to your program) without even checking whether any parameters were passed in.
This is easily solved: args is an array, and arrays can reveal their size. If the size doesn’t
match what you expect, you can bail out.

Add this code at the start of the Main() method:

```csharp
if (args.Length != 2) {
    Console.WriteLine("You must provide exactly two parameters!" dando;
    return;
}
```

The new piece of code in there is return, which is a C# keyword that forces it to exit the
current method. As Main() is the only method being called, this has the effect of termi-
nating the program because the user didn’t supply two parameters. You could also specify
that the Main() method have a return type of int so that an exit code would be returned
instead of returning without any feedback. This would be especially helpful if the
executable was to be used in a command line tool chain by another tool that needs feed-
back after your tool runs.

Using the Length property of args, it is now possible for you to write your own Main() method that does different things, depending on how many parameters are provided. To do
this properly, you need to use the else statement and nest multiple if statements like this:

```csharp
if (args.Length == 2) {
    /// whatever...
} else if (args.Length == 3) {
    /// something else
} else if (args.Length == 4) {
    /// even more
} else {
    /// only executed if none of the others are
}
```
Building on Mono’s Libraries

Ubuntu ships with several Mono-built programs such as Tomboy and gBrainy. It also comes with a fair collection of .NET-enabled libraries, some of which you probably already installed earlier. The nice thing about Mono, like many other object-oriented languages, is that it lets you build on these libraries really easily: You just import them with a using statement, then get started.

To demonstrate how easy it is to build more complicated Mono applications, we’re going to produce one using Gtk#, the GUI toolkit that is the standard for GNOME development.

Creating a GUI with Gtk#

Gtk# was included with Gnome by default for the first time in Gnome 2.16, but it had been used for a couple of years before that and so was already mature. MonoDevelop comes with its own GUI designer called GTK# Designer, which lets you drag and drop GUI elements onto your windows to design them.

To get started, in MonoDevelop go to File, New, Solution, choose C#, then Gtk# 2.0 project. Call it GtkTest, and deselect the box asking MonoDevelop to make a separate directory for the solution. Click Forward. In the New Solution Project Features window, all you need is already selected, so click OK.

You’ll find that Main.cs contains a little more code this time because it needs to create and run the Gtk# application. However, the actual code to create your GUI is in the User Interface section in the left pane. If you open that group, you’ll see Stock Icons and MainWindow. Double-click MainWindow to bring up MonoDevelop’s GUI designer.

Click Toolbox on the left of the screen to drag and drop the different window widgets onto your form to see what properties they have.

For now, drag a button widget onto your form. It automatically takes up all the space on your window. If you don’t want this to happen, try placing one of the containers down first, then putting your button in there. For example, if you want a menu bar at the top, then a calendar, then a status bar, you ought to drop the VBox pane onto the window first, then drop each of those widgets into the separate parts of the VPane, the main GUI creation workspace.

Your button will display the text “GtkButton” and use the variable name “button1” by default. Click to select it, then Properties on the right and look for Label in the Button Properties group. Change the label to “Hello.” Just at the top of the properties pane is a tab saying Properties (where you are right now), and another saying Signals. Signals are the events that happen to your widgets, such as the mouse moving over them, someone typing, or, of interest to us, when your button has been clicked. Look inside the Button Signals group for Clicked and double-click it. MonoDevelop automatically switches you to the code view, with a pre-created method to handle button clicks.

Type this code into the method:

button1.Label = "World!";
If you want to change the button's variable name, you do so from the same Properties tab using the first entry, Name. Change the Name value and your variable's name is changed. Press F5 to compile and run, and try clicking the button!

Reference

- www.mono-project.com/—The homepage of the Mono project is packed with information to help you get started. You can also download new Mono versions from here, if there’s something you desperately need.

- www.monodevelop.com/—The MonoDevelop project has its own site, which is the best place to look for updates.

- www.icsharpcode.net/OpenSource/SD/—MonoDevelop started life as a port of SharpDevelop. If you happen to dual-boot on Windows, this might prove very useful to you.

- http://msdn.microsoft.com/vcsharp/—We don’t print many Microsoft URLs in this book, but this one is important: It’s the homepage of their C# project, which can be considered the spiritual home of C# itself.

- Jesse Liberty’s *Programming C#* (O’Reilly, ISBN 0-596-00699-3) is compact, it’s comprehensive, and it’s competitively priced.

- If you’re very short on time and want the maximum detail (admittedly, with rather limited readability), you should try *The C# Programming Language*, which was co-authored by the creator of C#, Anders Hejlsberg (Addison-Wesley, ISBN: 0-321-33443-4).

In this chapter, we look at the options you have to manage your software in Ubuntu. If you are used to a Windows environment where you are reliant on visiting different vendor websites to download updates, you are in for a pleasant surprise! Updating a full Ubuntu installation, including all the application software, is as simple as running the Update Manager program. You will discover just how easy it is to install and even remove various software packages.

Ubuntu provides a variety of tools for system resource management. The following sections introduce the graphical software management tools that you will use for most of your software management. This chapter also covers monitoring and managing memory and disk storage on your system.

**Ubuntu Software Center**

The Ubuntu Software Center is a graphical utility for package management in Ubuntu. You will find it in the Applications menu as Ubuntu Software Center; it is named software-center. The Ubuntu Software Center allows you to easily select and install a large array of applications by using the intuitive built-in search and easy one-click installation. When you open the program, you will see the Package Browsing screen, as shown in Figure 32.1.

Along the left side of the screen, you will see three menu options: Get Software, Installed Software, and History. At the top is a search bar that you can use to search for packages. When you click the Get Software link, you will be
presented with options to explore software provided by Ubuntu or software for purchase. Clicking the Installed Software link will present you with a list of all the installed applications on your Ubuntu desktop.

![Ubuntu Software Center](image.png)

**FIGURE 32.1** The initial Ubuntu Software Center screen allows you to browse through packages sorted by groups.

Installing new software via Ubuntu Software Center is as simple as finding it in the package list, double-clicking, and clicking the Install button. When you do so, you may be asked for your password; then the application will be downloaded and installed. You can remove an application by finding it in Ubuntu Software Center and clicking the Remove button.

Use the Search box at the top to search for a specific application in the list. Note that this searches within the current category; so if you are in the Games category and search for “office,” you will get no results. The best place to search is within the Get Free Software category, to make sure you search all areas.

### Using Synaptic for Software Management

The Add/Remove Applications dialog works just fine for adding applications, but if you need to install something very specific—such as a library—or if you want to reconfigure your installation system, you need to use Synaptic (see Figure 32.2). You can run Synaptic by selecting it from the System, Administration, Synaptic Package Manager menu option.

At first glance, Synaptic looks a little like the Add/Remove Applications window. Along the left are software categories (although this time there are more of them), along the top right are the package selections for that category, and on the bottom right is the Package Information window that shows information about the currently selected package. To
install or remove software, click the check box to the left of its name, and you’ll see a menu that offers the following options:

- **Unmark**—If you have marked this package for installation, upgrade, or one of the other options, this removes that mark.
- **Mark for Installation**—Add this package to the list that will be installed.
- **Mark for Re-installation**—If you have some software already installed, but for some reason it’s not working, this reinstalls it from scratch.
- **Mark for Upgrade**—If the software has updates available, this will download and install them.
- **Mark for Removal**—This deletes the selected package from your system, but leaves its configuration files intact so that if you ever reinstall it you do not have to reconfigure it.
- **Mark for Complete Removal**—This deletes the selected package from your system, but also removes any configuration files, purging everything from the system.

After you have made your changes, click the Apply button to have Synaptic download, install, upgrade, and uninstall as necessary. If you close the program without clicking Apply, your changes will be lost.

Beneath the categories on the left side of the screen, you will see four buttons: Sections, Status, Search, and Custom, with Sections selected. These customize the left list: Sections is the Categories view, Status lets you view packages that are installed or upgradable, Search stores results of your searches, and Custom has some esoteric groupings that are useful only to advanced users.
You can press Ctrl+F at any time to search for a particular package. By default it is set to search by package name, but it is quite common to change the Look In box to Description and Name. As mentioned already, your search terms are saved under the Search view (the button on the bottom left), and you can click from that list to re-search on that term.

As well as providing the method of installing and removing software, Synaptic provides the means to configure the servers you want to use for finding packages. In fact, this is where you can make one of the most important changes to your Ubuntu system: You can open it up to the Debian universe and multiverse.

Ubuntu is based on the Debian distribution, which has more than 15,000 software packages available for installation. Ubuntu uses only a small subset of that number, but makes it easy for you to enable the others. When you use Synaptic, you will see small orange Ubuntu logos next to every package; this identifies them as being officially supported by the Ubuntu developers. The other, non-Ubuntu packages you can enable will not have this logo, but they are still supported by the Debian developers.

To enable the Universe and Multiverse repositories, go to Settings, Repositories. This list shows all the servers you have configured for software installation and updates, and will include the Universe and Multiverse repositories. When you find them, check them, and then click Close.

Synaptic shows a message box warning you that the repository listings have changed and that you need to click the Reload button (near the top left of the Synaptic window) to have it refresh the package lists. Go ahead and do that, and you should see a lot more software appear for your selection. However, notice that only a small number have the official Ubuntu “seal” attached, which means you need to be a bit more careful when installing software!

**NOTE**

Much of the software discussed in this book is available only through the Universe repository. As such, we highly recommend enabling it to get full use out of this book and your Ubuntu installation.

**Staying Up-to-Date**

Although you can manage your software updates through Synaptic, Ubuntu provides a dedicated tool in the form of Update Manager (launched through System, Administration, Update Manager, and shown in Figure 32.3). This tool is designed to be simple to use: when you run it, Update Manager automatically downloads the list of updates available and checks them all in the list it shows. If the update list was downloaded automatically not too long ago, you can force Ubuntu to refresh the list of available updates by clicking the Check button. Otherwise, all you need to do is click Install Updates and your system will be brought up-to-date. If you want a little more information about the updates, click Show Details at the bottom to see what has changed in the update.
Ubuntu automatically checks for updates periodically and notifies you when critical updates are available. However, there’s no harm running Update Manager yourself every so often, just to make sure; it’s better to be safe than sorry.

**Working on the Command Line**

With so much software available for installation, it is no surprise that Debian-based distros have many ways to manage software installation. At their root, however, they all use Debian’s world-renowned Advanced Package Tool (APT). A person posting on Slashdot.com once said, “Welcome to Slashdot. If you can’t think of anything original, just say how much APT rocks and you’ll fit right in.” You see, even though many other distros have tried to equal the power of APT, nothing else even comes close.

Why is APT so cool? Well, it was the first system to properly handle dependencies in software. Other distros, such as Red Hat, used RPM files that had dependencies. For example, an RPM for Gimp would have a dependency on Gtk, the graphical toolkit on which Gimp is based. As a result, if you tried to install your Gimp RPM without having the Gtk RPM, your install would fail. So you grab the Gtk RPM and try again. Aha: Gtk has a dependency on three other things that you need to download. And those three other things have dependencies on 20 other things. And so on, and so on, usually until you can’t find a working RPM for one of the dependencies, and you give up.
APT, on the other hand, was designed to automatically find and download dependencies for your packages. So if you wanted to install Gimp, it would download Gimp’s package as well as any other software it needed to work. No more hunting around by hand, no more worrying about finding the right version, and certainly no more need to compile things by hand. APT also handles installation resuming, which means that if you lose your Internet connection part-way through an upgrade (or your battery runs out, or you have to quit, or whatever), APT will pick up where it left off the next time you rerun it.

**Day-to-Day Usage**

To enable you to search for packages both quickly and thoroughly, APT uses a local cache of the available packages. Try running this command:

```
matthew@seymour:~$ sudo apt-get update
```

The `apt-get update` command instructs APT to contact all the servers it is configured to use and download the latest list of file updates. If your lists are outdated, it takes a minute or two for APT to download the updates. Otherwise, this command executes it in a couple of seconds.

After the latest package information has been downloaded, you are returned to the command line. You can now ask APT to automatically download any software that has been updated, using this command:

```
matthew@seymour:~$ sudo apt-get upgrade
```

If you have a lot of software installed on your machine, there is a greater chance of things being updated. APT scans your software and compares it to the latest package information from the servers and produces a report something like this:

```
matthew@seymour:~$ sudo apt-get upgrade
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following packages will be upgraded:
 cabextract google-chrome-beta icedtea6-plugin language-pack-en
 libfreetype6 libfreetype6-dev libsmbclient libwbclient0 openjdk-6-jre
 openjdk-6-jre-headless openjdk-6-jre-lib samba-common samba-common-bin
 smbclient upstart winbind xserver-common xserver-xorg-core
21 upgraded, 0 newly installed, 0 to remove and 0 not upgraded.
Need to get 84.8MB of archives.
After this operation, 623kB of additional disk space will be used.
Do you want to continue [Y/n]?
```

Each part of that report tells us something important. Starting at the top, the line “the following packages will be upgraded” gives us the exact list of packages for which updates are available. If you’re installing new software or removing software, you’ll see lists titled “The following packages will be installed” and “The following packages will be removed.” A summary at the end shows a total of 21 packages that APT will upgrade, with 0 new packages, 0 to remove, and 0 not upgraded. Because this is an upgrade rather than an
installation of new software, all those new packages will take up only 623KB of additional space. Although we have an 84.8MB download, the packages are overwriting existing files.

It’s important to understand that a basic apt-get upgrade will never remove software or add new software. As a result, it is safe to use to keep your system fully patched, because it should never break things. However, occasionally you will see the “0 not upgraded” status change, which means some things cannot be upgraded. This happens when some software must be installed or removed to satisfy the dependencies of the updated package, which, as previously mentioned, apt-get upgrade will never do.

In this situation, you need to use apt-get dist-upgrade, so named because it’s designed to allow users to upgrade from one version of Debian/Ubuntu to a newer version—an upgrade that inevitably involves changing just about everything on the system, removing obsolete software, and installing the latest features. This is one of the most-loved features of Debian because it allows you to move from version to version without having to download and install new CDs. Keeping regular upgrades and dist-upgrades separate is very useful for making sure that security updates and simple bug fixes don’t change software configurations that you may be counting on, especially on a machine that needs to be consistently available and working, such as a server.

Whereas apt-get upgrade and apt-get dist-upgrade are there for upgrading packages, apt-get install is responsible for adding new software. For example, if you want to install the MySQL database server, you would run this:

```bash
matthew@seymour:~$ sudo apt-get install mysql-server
```

Internally, APT would query “mysql-server” against its list of software and find that it matches the mysql-server-5.0 package. It would then find which dependencies it needs that you don’t already have installed and give you a report like this one:

```bash
matthew@seymour:~$ sudo apt-get install mysql-server
Reading package lists... Done
Building dependency tree... Done
The following extra packages will be installed:
  libdbd-mysql-perl libdbi-perl libnet-daemon-perl libplrpc-perl
  mysql-client-5.0 mysql-server-5.0
Suggested packages:
  dbishell libcompress-zlib-perl
Recommended packages:
  mailx
The following NEW packages will be installed
  libdbd-mysql-perl libdbi-perl libnet-daemon-perl libplrpc-perl
  mysql-client-5.0 mysql-server mysql-server-5.0
0 upgraded, 7 newly installed, 0 to remove and 11 not upgraded.
Need to get 28.5MB of archives.
After unpacking 65.8MB of additional disk space will be used.
Do you want to continue [Y/n]?
```
This time, you can see that APT has picked up and selected all the dependencies required to install MySQL Server 5.0, but it has also listed one recommended package and two suggested packages that it has not selected for installation. The “recommended” package is just that: The person who made the MySQL package (or its dependencies) thinks it would be a smart idea for you to also have the mailx package. If you want to add it, press N to terminate apt-get and rerun it like this:

```
matthew@seymour:~$ apt-get install mysql-server mailx
```

The “suggested” packages are merely a lower form of recommendation. They don’t add any crucial features to the software you selected for install, but it’s possible that you might need them for certain smaller things.

### NOTE

APT maintains a package cache where it stores .deb files it has downloaded and installed. This usually lives in `/var/cache/apt/archives` and can sometimes take up many hundreds of megabytes on your computer. You can have APT clean out the package cache by running `apt-get clean`, which deletes all the cached .deb files. Alternatively, you can run `apt-get autoclean`, which deletes cached .deb files that are beyond a certain age, thereby keeping newer packages.

If you try running `apt-get install` with packages you already have installed, APT considers your command to be `apt-get update` and looks to see whether new versions are available for download.

The last day-to-day package operation is removing things you no longer want. This is done through the `apt-get remove` command, as follows:

```
matthew@seymour:~$ apt-get remove firefox
```

Removing packages can be dangerous, because APT also removes any software that relies on the packages you selected. For example, if you were to run `apt-get remove libgtk2.0-0` (the main graphical toolkit for Ubuntu), you would probably find that APT insists on removing more than a hundred other things. The moral of the story is this: When you remove software, read the APT report carefully before pressing Y to continue with the uninstall.

A straight `apt-get remove` leaves behind the configuration files of your program so that if you ever reinstall it you do not also need to reconfigure it. If you want the configuration files removed as well as the program files, run this command instead:

```
matthew@seymour:~$ apt-get remove --purge firefox
```

That performs a full uninstall.

### NOTE

You can see a more extensive list of `apt-get` parameters by running `apt-get` without any parameters. The cryptic line at the bottom, “This APT has Super Cow Powers,” is made even more cryptic if you run the command `apt-get moo`.

Finding Software

With so many packages available, it can be hard to find the exact thing you need using command-line APT. The general search tool is called *apt-cache* and is used like this:

```
matthew@seymour:~$ apt-cache search kde
```

Depending on which repositories you have enabled, that tool will return about a thousand packages. Many of those results will not even have KDE in the package name, but will be matched because the description contains the word KDE.

You can filter through this information in several ways. First, you can instruct *apt-cache* to search only in the package names, not in their descriptions. This is done with the `–n` parameter, like this:

```
matthew@seymour:~$ apt-cache –n search kde
```

Now the search has gone down from more than 1,000 packages to a few hundred.

Another way to limit search results is to use some basic regular expressions, such as `^`, meaning “start,” and `$`, meaning “end.” For example, you might want to search for programs that are part of the main KDE suite and not libraries (usually named something like `libkde`), additional bits (such as `xmms-kde`), and things that are actually nothing to do with KDE yet still match our search (like `tkdesk`). This can be done by searching for packages that have a name starting with `kde`, as follows:

```
matthew@seymour:~$ apt-cache –n search ^kde.
```

Perhaps the easiest way to find packages is to combine *apt-cache* with *grep*, to search within search results. For example, if you want to find all games-related packages for KDE, you could run this search:

```
matthew@seymour:~$ apt-cache search games | grep kde
```

When you’ve found the package you want to install, run it through *apt-get install* as per usual. If you first want a little more information about that package, you can use *apt-cache showpkg*, like this:

```
matthew@seymour:~$ apt-cache showpkg mysql-server-5.0
```

This shows information on “reverse depends” (which packages require, recommend, or suggest `mysql-server-5.0`), “dependencies” (which packages are required, recommended, or suggested to install `mysql-server-5.0`) and “provides” (which functions this package gives you). The “provides” list is quite powerful because it allows different packages to provide a given resource. For example, a MySQL database-based program requires MySQL to be installed, but isn’t fussy whether you install MySQL 4.1 or MySQL 5.0. In this situation, the Debian packages for MySQL 4.1 and MySQL 5.0 will both have “mysql-server-4.1” in the provides list, meaning that they offer the functionality provided by MySQL 4.1. As a result, you can install either version to satisfy the MySQL-based application.

Compiling Software from Source

Compiling applications from source is not that difficult. Most source code is available as compressed source *tarballs*—that is, *tar* files that have been compressed using *gzip* or *bzip*. The compressed files typically uncompress into a directory containing several files. It is
always a good idea to compile source code as a regular user to limit any damage that broken or malicious code might inflict, so create a directory named source in your home directory.

From wherever you downloaded the source tarball, uncompress it into the ~/source directory using the -C option to tar:

```
matthew@seymour:~$ tar zxfv packagename.tgz -C ~/source
matthew@seymour:~$ tar zxfv packagename.tar.gz -C ~/source
matthew@seymour:~$ tar jxfv packagename.bz -C ~/source
matthew@seymour:~$ tar jxfv packagename.tar.bz2 -C ~/source
```

If you are not certain what file compression method was used, use the file command to figure it out:

```
matthew@seymour:~$ file packagename
```

Now, change directories to ~/source/packagename and look for a file named README, INSTALL, or a similar name. Print out the file if necessary because it contains specific instructions on how to compile and install the software. Typically, the procedure to compile source code is as follows:

```
matthew@seymour:~/source/packagename$ ./configure
```

This runs a script to check whether all dependencies are met and the build environment is correct. If you are missing dependencies, the configure script normally tells you exactly which ones it needs. If you have the Universe and Multiverse repositories enabled in Synaptic, chances are you will find the missing software (usually libraries) in there.

When your configure script succeeds, run the following to compile the software:

```
matthew@seymour:~/source/packagename$ make
```

And finally, run the following:

```
matthew@seymour:~/source/packagename$ sudo make install.
```

If the compile fails, check the error messages for the reason and run the following before you start again:

```
matthew@seymour:~/source/packagename$ make clean
```

You can also run the following to remove the software if you do not like it:

```
matthew@seymour:~/source/packagename$ sudo make uninstall
```

No computer with a connection to the Internet is 100 percent safe. If this information does not concern you, it should! Although there is no way to guarantee the ability to stop patient, creative, and serious crackers who are intent on getting into your computer or network, there are ways to make it harder for them and to warn you when they do.

In this chapter, we discuss all aspects of securing your Linux machines. You might have wondered why we did not spread this information around the book wherever it was appropriate, but the reason is simple: If you ever have a security problem with Linux, you know you can turn to this page and start reading without having to search or try to remember where you saw a tip. Everything you need is here in this one chapter, and we strongly advise you read it from start to finish.

**BUILT-IN PROTECTION IN THE KERNEL**

A number of networking and low-level protective services are built in to the Linux kernel. These services can be enabled, disabled, or displayed using the `sysctl` command, or by echoing a value (usually a 1 or a 0 to turn a service on or off) to a kernel process file under the `/proc` directory.

**Understanding Computer Attacks**

There are many ways in which computer attacks can be divided for classification. Perhaps the easiest dichotomy is...
to separate attacks as *internal*, which are computer attacks done by someone with access to a computer on the local network, and *external*, which are attacks by someone with access to a computer through the Internet. This might sound like a trivial separation to make, but it is actually important: Unless you routinely hire talented computer crackers or allow visitors to plug computers into your network, the worst internal attack you are likely encounter is from a disgruntled employee.

### Hacker versus Cracker

In earlier days, there was a distinction made between the words *hacker* and *cracker*. A hacker was someone who used technology to innovate in new or unusual ways, whereas a cracker was someone who used technology to attack another’s computers and cause harm. In the original definition, hackers did good or cool things and crackers did bad things.

This distinction was lost on the general public, so the term *hacker* has now regretfully come to mean the same thing as *cracker* for most people. However, we recognize the distinction and use the term cracker to mean a malicious person using a computer to cause problems for others. In your real-world conversations, you should realize most people will not make a distinction, and you should be prepared to define your terms if you call yourself a hacker.

Although you should never ignore the internal threat, you should arguably be more concerned with the outside world. The big bad Internet is a security vortex. Machines connected directly to the outside world can be attacked by people across the world, and invariably are, even only a few minutes after having been connected.

This situation is not a result of malicious users lying in wait for your IP address to do something interesting. Instead, canny virus writers have created worms that exploit a vulnerability, take control of a machine, and then spread it to other machines around them. As a result, most attacks today are the result of these autocracking tools; there are only a handful of true clever crackers around, and, to be frank, if one of them ever actually targets you seriously, it will take a mammoth effort to repel the cracker, regardless of which operating system you run.

Autocracking scripts also come in another flavor: prewritten code that exploits a vulnerability and gives its users special privileges on the hacked machine. These scripts are rarely used by their creators; instead, they are posted online and downloaded by wannabe hackers, who then use them to attack vulnerable machines.

So, the external category is itself made up of worms, serious day job crackers, and wannabe crackers (usually called *script kiddies*). Combined they will assault your Internet-facing servers, and it is your job to make sure your boxes stay up, happily ignoring the firefight around them.

On the internal front, things are somewhat more difficult. Users who sit inside your firewall are already past your primary source of defense and, worse, they might even have physical access to your machines. Anyone with malicious intent and physical access to a machine is
nearly impossible to stop unless they are simply inept. The situation is only slightly better if they don’t have physical access but do have access to your internal network.

Regardless of the source of the attack, you can follow a five-step checklist to secure your box:

1. Assess your vulnerability. Decide which machines can be attacked, which services they are running, and who has access to them.
2. Configure the server for maximum security. Install only what you need, run only what you must, and configure a local firewall.
3. Secure physical access to the server.
4. Create worst-case-scenario policies.
5. Keep up-to-date with security news.

Each of these is covered in the following sections, and each is as important as the others.

Assessing Your Vulnerability

It is a common mistake for people to assume that switching on a firewall makes them safe. This is not the case and, in fact, has never been the case. Each system has distinct security needs, and taking the time to customize its security layout will give you maximum security and the best performance.

The following list summarizes the most common mistakes:

- **Installing every package**—Do you plan to use the machine as a DNS server? If not, why have BIND installed? Go through and ensure that you have only the software you need.

- **Enabling unused services**—Do you want to administer the machine remotely? Do you want people to upload files? If not, turn off SSH and FTP because they just add needless attack vectors. This goes for many other services.

- **Disabling the local firewall on the grounds that you already have a firewall at the perimeter**—In security, depth is crucial: The more layers someone has to hack through, the higher the likelihood the cracker will give up or get caught.

- **Letting your machine give out more information than it needs to**—Many machines are configured to give out software names and version numbers by default, which is just giving crackers a helping hand.

- **Placing your server in an unlocked room**—If so, you might as well just turn it off now and save the worry. The exception to this is if all the employees at your company are happy and trustworthy. But why take the risk?

- **Plugging your machine into a wireless network**—Unless you need wireless, avoid it, particularly if your machine is a server. Never plug a server into a wireless network because it is just too fraught with security problems.

After you have ruled out these, you are onto the real problem: Which attack vectors are open on your server? In Internet terms, this comes down to which services are Internet-facing and which ports they are running on.
Two tools are often used to determine your vulnerabilities: Nmap and Nessus. Nessus scans your machine, queries the services running, checks their version numbers against its list of vulnerabilities, and reports problems.

Although Nessus sounds clever, it does not work well in many modern distributions (Ubuntu included) because of the way patches are made available to software. For example, if you’re running Apache 2.0.52 and a bug is found that’s fixed in 2.0.53, Ubuntu backports that patch to 2.0.52. This is done because the new release probably also includes new features that might break your code, so the Ubuntu team takes only what is necessary and copies it into your version. As a result, Nessus will see the version 2.0.52 and think it is vulnerable to a bug that has in fact been backported.

The better solution is to use Nmap, which scans your machine and reports on any open TCP/IP ports it finds. Any service you have installed that responds to Nmap’s query is pointed out, which enables you to ensure that you have locked everything down as much as possible.

Nmap is available to install from the Ubuntu software repositories. Although you can use Nmap from a command line, it is easier to use with the front end—at least until you become proficient. To run the front end, open a terminal and run `nmapfe`. If you want to enable all Nmap’s options, you need to have administrator privileges and run `sudo nmapfe`.

When you run Nmap (click the Scan button), it tests every port on your machine and checks whether it responds. If it does respond, Nmap queries it for version information and then prints its results onscreen.

The output lists the port numbers, service name (what usually occupies that port), and version number for every open port on your system. Hopefully, the information Nmap shows you will not be a surprise. If there is something open that you do not recognize, it could be that a cracker placed a backdoor on your system to allow easy access, so you should check into it further.

You should use the output from Nmap to help you find and eliminate unwanted services. The fewer services that are open to the outside world, the more secure you are. Only use Nmap on systems that you own. It is impolite to scan other people’s servers and you may also be accused of doing so in preparation for illegal activity.

**Protecting Your Machine**

After you have disabled all the unneeded services on your system, what remains is a core set of connections and programs that you want to keep. However, you are not finished yet: You need to clamp down your wireless network, lock your server physically, and put scanning procedures in place (such as Tripwire and promiscuous mode network monitors).
Securing a Wireless Network

Because wireless networking has some unique security issues, those issues deserve a separate discussion here.

Wireless networking, although convenient, can be very insecure by its very nature because transmitted data (even encrypted data) can be received by remote devices. Those devices could be in the same room; in the house, apartment, or building next door; or even several blocks away. Extra care must be used to protect the actual frequency used by your network. Great progress has been made in the past couple of years, but the possibility of a security breach is increased when the attacker is in the area and knows the frequency on which to listen. It should also be noted that the encryption method used by more wireless NICs is weaker than other forms of encryption (such as SSH) and should not be considered as part of your security plan.

TIP

Always use OpenSSH-related tools, such as ssh or sftp, to conduct business on your wireless LAN. Passwords are not transmitted as plain text, and your sessions are encrypted. See Chapter 15, “Remote Access with SSH and Telnet,” to see how to connect to remote systems using ssh.

The better the physical security is around your network, the more secure it will be (this applies to wired networks as well). Keep wireless transmitters (routers, switches, and so on) as close to the center of your building as possible. Note or monitor the range of transmitted signals to determine whether your network is open to mobile network sniffing—now a geek sport known as war driving. Wireshark is an example of a program that is useful for analyzing wireless traffic (as well as all network activity) and can be installed from the Ubuntu repositories with more information at www.wireshark.org/. An occasional walk around your building not only gives you a break from work, but can also give you a chance to notice any people or equipment that should not be in the area.

Keep in mind that it takes only a single rogue wireless access point hooked up to a legitimate network hub to open access to your entire system. These access points can be smaller than a pack of cigarettes, so the only way to spot them is to scan for them with another wireless device.

Passwords and Physical Security

The next step toward better security is to use secure passwords on your network and ensure that users use them as well. For somewhat more physical security, you can force the use of a password with the GRUB bootloader, remove bootable devices such as floppy and CD-ROM drives, or configure a network-booting server for Ubuntu.

Also, keep in mind that some studies show that as many as 90 percent of network break-ins are by current or former employees. If a person no longer requires access to your
network, lock out access or, even better, remove the account immediately. A good security policy also dictates that any data associated with the account first be backed up and retained for a set period of time to ensure against loss of important data. If you are able, remove the terminated employee from the system before the employee leaves the building. Finally, be aware of physical security. If a potential attacker can get physical access to your system, getting full access becomes trivial. Keep all servers in a locked room, and ensure that only authorized personnel are given access to clients.

**Configuring and Using Tripwire**

Tripwire is a security tool that checks the integrity of normal system binaries and reports any changes to syslog or by email. Tripwire is a good tool for ensuring that your binaries have not been replaced by Trojan horse programs. *Trojan horses* are malicious programs inadvertently installed because of identical filenames to distributed (expected) programs, and they can wreak havoc on a breached system.

There are two versions of Tripwire, an open source version and a commercial product. The free version of Tripwire is available in the Ubuntu repositories. You can find out about the differences at www.tripwire.org.

To initialize Tripwire, use its `-init` option like this:

```
matthew@seymour~:$ sudo tripwire -init
```

Please enter your local passphrase:

```
Parsing policy file: /etc/tripwire/tw.pol
Generating the database...
*** Processing Unix File System ***
....
Wrote database file: /var/lib/tripwire/shuttle2.twd
The database was successfully generated.
```

Note that not all the output is shown here. After Tripwire has created its database (which is a snapshot of your file system), it uses this baseline along with the encrypted configuration and policy settings under the `/etc/tripwire` directory to monitor the status of your system. You should then start Tripwire in its integrity checking mode, using a desired option. (See the tripwire manual page for details.) For example, you can have Tripwire check your system and then generate a report at the command line, like this:

```
matthew@seymour~:$ sudo tripwire -m c
```

No output is shown here, but a report is displayed in this example. The output could be redirected to a file, but a report is saved as `/var/lib/tripwire/report/hostname-YYYYYMDD-HHmmSS.twr` (in other words, using your host's name, the year, the month, the day, the hour, the minute, and the seconds). This report can be read using the `twprint` utility, like this:

```
matthew@seymour~:$ sudo twprint -print-report -r /var/lib/tripwire/report/shuttle2-20020919-181049.twr | less
```

Other options, such as emailing the report, are supported by Tripwire, which should be run as a scheduled task by your system's scheduling table, `/etc/crontab`, on off-hours.
Viruses can be resource intensive on less powerful computers.) The Tripwire software package also includes a twadmin utility you can use to fine-tune or change settings or policies or to perform other administrative duties.

Plan to spend some time reading documentation if you want to use Tripwire. It is powerful, but not simple. We recommend starting with the man pages and www.tripwire.com.

**Devices**

Do not ever advertise that you have set a NIC to promiscuous mode. Promiscuous mode (which can be set on an interface by using ifconfig's promisc option) is good for monitoring traffic across the network and can often allow you to monitor the actions of someone who might have broken into your network. The tcpdump command also sets a designated interface to promiscuous mode while the program runs; unfortunately, the ifconfig command does not report this fact while tcpdump is running!

Remember to use the right tool for the right job. Although a network bridge can be used to connect your network to the Internet, it would not be a good option. Bridges have almost become obsolete because they forward any packet that comes their way, which is not good when a bridge is connected to the Internet. A router enables you to filter which packets are relayed.

**Viruses**

In the right hands, Linux is every bit as vulnerable to viruses as Windows is. That might come as a surprise to you, particularly if you made the switch to Linux on the basis of its security record. However, the difference between Windows and Linux is that it is much easier to secure against viruses on Linux. Indeed, as long as you are smart and diligent, you need never worry about them. Here is why:

- Linux never puts the current directory in your executable path, so typing ls runs /bin/ls rather than any program named ls in the current directory.
- A non-root user can infect only the files that user has write access to, which is usually only the files in the user's home directory. This is one of the most important reasons for never using sudo when you don't need to!
- Linux forces you to manually mark files as executable, so you can't accidentally run a file called myfile.txt.exe, thinking it was just a text file.
- By having more than one common web browser and email client, Linux has strength through diversity: Virus writers cannot target one platform and hit 90 percent of the users.

Despite saying all that, Linux is susceptible to being a carrier for viruses. If you run a mail server, your Linux box can send virus-infected mails on to Windows boxes. The Linux-based server would be fine, but the Windows client would be taken down by the virus.

In this situation, you should consider a virus scanner for your machine. You have several to choose from, both free and commercial. The most popular free suite is Clam AV
(www.clamav.net), but Central Command, BitDefender, F-Secure, Kaspersky, McAfee, and others all compete to provide commercial solutions—look around for the best deal before you commit.

**Configuring Uncomplicated Firewall (UFW)**

Always use a hardware-based or software-based firewall on computers connected to the Internet. Ubuntu has a firewall application installed by default named UFW or Uncomplicated Firewall. This tool allows you to implement selective or restrictive policies regarding access to your computer or LAN.

UFW is run from the terminal, and you must have administrative privileges to use it. Commands are given like this:

```
matthew@seymour~:$ sudo ufw status
```

The most useful commands are listed in Table 33.1. For others, see `man ufw`. Many are described in greater detail after the table.

<table>
<thead>
<tr>
<th>TABLE 33.1 Useful commands for UFW</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage: UFW COMMAND</td>
</tr>
<tr>
<td>Commands:</td>
</tr>
<tr>
<td>enable</td>
</tr>
<tr>
<td>disable</td>
</tr>
<tr>
<td>reload</td>
</tr>
<tr>
<td>default allow</td>
</tr>
<tr>
<td>logging on</td>
</tr>
<tr>
<td>allow ARGS</td>
</tr>
<tr>
<td>deny ARGS</td>
</tr>
<tr>
<td>reject ARGS</td>
</tr>
<tr>
<td>limit ARGS</td>
</tr>
<tr>
<td>delete RULE</td>
</tr>
<tr>
<td>status shows</td>
</tr>
<tr>
<td>status numbered</td>
</tr>
<tr>
<td>status verbose</td>
</tr>
<tr>
<td>show REPORT</td>
</tr>
<tr>
<td>—version</td>
</tr>
</tbody>
</table>

By default the UFW or firewall is disabled. To enable the firewall you will run the following command:

```
matthew@seymour~:$ sudo ufw enable
```

To disable replace enabled with disabled.
Next, we will want to enable firewall logging. Much like the enable command we will run the following command:

```
matthew@seymour~:$ sudo ufw logging on
```

To enable specific ports on the firewall you can run UFW command along with the port number to open. For example if you want to allow port 80 (http) incoming connections to your Ubuntu server you would enter the following:

```
matthew@seymour~:$ sudo ufw allow 80
```

To remove the firewall rule allowing port 80 connections run the following command:

```
matthew@seymour~:$ sudo ufw delete allow 80
```

Many services are already defined in ufw. This means you don’t have to remember the standard ports those services use and you can allow, deny or delete using the service name, like this:

```
matthew@seymour~:$ sudo ufw allow ssh
```

You can also allow incoming connections from particular IP addresses, for example if you want to let 192.168.0.1 to connect to your server you would enter the following:

```
matthew@seymour~:$ sudo ufw allow from 192.168.0.1
```

To remove the firewall rule allowing the previous IP address to connect you would run the following command:

```
matthew@seymour~:$ sudo ufw delete allow from 192.168.0.1
```

There is also a graphical interface that can be installed from the Ubuntu repositories to manage UFW called GUFW. If you install it, you can open GUFW at System, Administration, Firewall configuration. The same details apply, but the interface is easier and does not require to remember as much, as you can see in Figure 33.1 where I have a rule to allow traffic in on port 22 (for the ssh service) and incoming traffic on port 5900 if it uses the tcp protocol (for the VNC service).

If you click Add you can add rules for preconfigured services easily, as shown in Figure 33.2, or you can configure your own rules from the Simple and Advanced tabs.

## AppArmor

AppArmor is a Mandatory Access Control (MAC) system. It is less complicated than the better known SELinux (www.nsa.gov/research/selinux/), a MAC created by the United States’ National Security Agency (NSA). AppArmor is designed to limit what specific programs can do by restricting them to the use of predetermined resources and only those resources. This is done via profiles, which are loaded into the kernel at boot. It can be run in complain mode, where information is logged about insecure practices but no action is taken, or in enforce mode where policies and limits are active.

This is a brief introduction to AppArmor. For a fuller introduction, checks the links listed in the Reference section, as well as take a look at this Ubuntu Forums thread: http://ubuntuforums.org/showthread.php?t=1008906.
By default, AppArmor does very little. You can install some extra profiles from the Ubuntu repositories by installing the `apparmor-profiles` package. These will run in complain mode and log issues in `/var/log/messages`.

To unleash the power of AppArmor, you need to edit or create text files in `/etc/apparmor.d`. Profiles are named for the application they restrict, including the full...
path to the application in the filesystem. For example, the file `/sbin/syslogd`, shown here, restricts the system logging daemon:

```
$Id$
# —————————————————————————————————
#    Copyright (C) 2002-2005 Novell/SUSE
#    This program is free software; you can redistribute it and/or
#    modify it under the terms of version 2 of the GNU General Public
#    License published by the Free Software Foundation.
# —————————————————————————————————
#include <tunables/global>

/sbin/syslogd flags=(complain) {
    #include <abstractions/base>
    #include <abstractions/nameservice>
    #include <abstractions/consoles>

capability sys_tty_config,
capability dac_override,
capability dac_read_search,
capability setuid,
capability setgid,
/dev/log                      wl,
/var/lib/*/dev/log            wl,
/dev/tty*                     w,
/dev/xconsole                rw,
/etc/syslog.conf              r,
/sbin/syslogd                 rmix,
/var/log/**                   rw,
/var/run/syslogd.pid          krwl,
/var/run/utmp                 rw,
/var/spool/compaq/nic/messages_fifo rw,
}
Even without knowing the syntax, we can see from this file that profiles are simple text files that support the use of comments, that absolute paths and globbing (pattern matching for filenames) are supported, that specific capabilities are allowed or disallowed, and what locations and programs in the filesystem may be accessed or used.

Each access rule specifies specific permissions from this list:

- `r` - read
- `w` - write
- `ux` - unconstrained execute
- `Ux` - unconstrained execute — scrub the environment
- `px` - discrete profile execute
- `Px` - discrete profile execute — scrub the environment
- `ix` - inherit execute
- `m` - allow PROT_EXEC with mmap(2) calls
- `l` - link

These permissions are listed at the end of lines.

Genprof is a program that helps you generate or update a profile. You supply the name of the executable (or the path, if it is not already in the path) and may optionally supply the path to the profiles as well.

```
matthew@seymour~:$ sudo genprof google-chrome
```

You will be asked to start the program and use it for a bit. After it is complete, you will be given an opportunity to choose whether access to each function should be allowed or denied. The program will then write a text file in /etc/apparmor.d using the name of the program and its path, in this case opt.google.chrome.google-chrome, which I installed directly from Google (www.google.com/chrome?platform=linux), so no premade Apparmor profile exists on my system. You may then edit the text file as desired, which you will need to do if you want to change from complain to enforce mode.

After you have a set of profiles that cover what you need, these are the commands you will use most often:

Start:
```
matthew@seymour~:$ sudo service apparmor start
```

Stop:
```
matthew@seymour~:$ sudo service apparmor stop
```

Reload:
```
matthew@seymour~:$ sudo service apparmor reload (or restart)
```

Show status:
```
matthew@seymour~:$ sudo service apparmor status
```

We have only scratched the surface of AppArmor, but hopefully enough to have whetted your appetite to do some further reading. AppArmor is still rather new and is changing. Online documentation is the best way to keep up. A few good places to start are included in the References section.
Forming a Disaster Recovery Plan

No one likes planning for the worst, which is why two thirds of people do not have wills. It is a scary thing to have your systems hacked: One or more criminals has broken through your carefully laid blocks and caused untold damage to the machine. Your boss, if you have one, will want a full report of what happened and why, and your users will want their email when they sit down at their desks in the morning. What to do?

If you ever do get hacked, nothing will take the stress away entirely. However, if you take the time to prepare a proper response in advance, you should at least avoid premature aging. Here are some tips to get you started:

- **Do not just pull the network cable out**—This acts as an alert that the cracker has been detected, which rules out any opportunities for security experts to monitor for that cracker returning and actually catch him.

- **Only inform the people who need to know**—Your boss and other IT people are at the top of the list; other employees are not. Keep in mind that it could be one of the employees behind the attack, and this tips them off.

- **If the machine is not required and you do not want to trace the attack, you can safely remove it from the network**—However, do not switch it off because some backdoors are enabled only when the system is rebooted.

- **Take a copy of all the log files on the system and store them somewhere else**—These might have been tampered with, but they might contain nuggets of information.

- **Check the**
  
  `/etc/passwd` file and look for users you do not recognize—Change all the passwords on the system, and remove bad users.

- **Check the output of**
  
  `ps aux` for unusual programs running—Also check to see whether any cron jobs are set to run.

- **Look in /var/www and see whether any web pages are there that should not be.**

- **Check the contents of the `.bash_history` files in the home directories of your users**—Are there any recent commands for your primary user?

- **If you have worked with external security companies previously, call them in for a fresh audit**—Hand over all the logs you have, and explain the situation. They will be able to extract all the information from the logs that is possible.

- **Start collating backup tapes from previous weeks and months**—Your system might have been hacked long before you noticed, so you might need to roll back the system more than once to find out when the attack actually succeeded.
Download and install Rootkit Hunter from www.rootkit.nl/projects/rootkit_hunter.html—This searches for (and removes) the types of files that bad guys leave behind for their return.

Keep your disaster recovery plan somewhere safe; saving it as a file on the machine in question is a very bad move!

Squeezing extra performance out of your hardware might sound like a pointless task given how cheap commodity upgrades are today. To a certain degree that is true—for most of us, it is cheaper to buy a new computer than to spend hours fighting to get a 5 percent speed boost. But what if the speed boost were 20 percent? How about if it were 50 percent?

The amount of benefit you can get by optimizing your system varies depending on what kinds of tasks you are running, but there is something for everyone. Over the next few pages we will be looking at quick ways to optimize the Apache web server, both the KDE and Gnome desktop systems, both MySQL and PostgreSQL database servers, and more.

Before we start, you need to understand that optimization is not an absolute term: If we optimize a system, we have improved its performance, but it is still possible it could further be increased. We are not interested in getting 99.999 percent performance out of a system, because optimization suffers from the law of diminishing returns—the basic changes make the biggest differences, but after that it takes increasing amounts of work to obtain decreasing speed improvements.

**Hard Disk**

Many Linux users love to tinker under the hood to increase the performance of their computers, and Linux gives you some great tools to do that. Whereas Moms tell us, “Don’t fix what’s not broken,” Dads often say, “Fix it until it
breaks.” In this section, you learn about many of the commands used to tune, or “tweak,” your file system.

Before you undertake any “under the hood” work with Linux, however, keep a few points in mind. First, perform a benchmark on your system before you begin. Linux does not offer a well-developed benchmarking application, and availability of what exists changes rapidly. You can search online for the most up-to-date information for benchmarking applications for Linux. If you are a system administrator, you might choose to create your own benchmarking tests. Second, tweak only one thing at a time so you can tell what works, what does not work, and what breaks. Some of these tweaks might not work or might lock up your machine.

Always have a working boot disc handy and remember that you are personally assuming all risks for attempting any of these tweaks. If you don’t understand what you are doing or are not confident in your ability to revert any changes discussed here, do not attempt any of the suggestions in this chapter. The default settings in Ubuntu work very well for most people and really don’t need adjusting; but some people like old 1960s muscle cars and enjoy tweaking and breaking and fixing them. This chapter is for that sort of person. If you don’t think you can fix it, don’t risk breaking it.

Using the BIOS and Kernel to Tune the Disk Drives

One method of tuning involves adjusting the settings in your BIOS. Because the BIOS is not Linux and every BIOS seems different, always read your motherboard manual for better possible settings and make certain that all the drives are detected correctly by the BIOS. Change only one setting at a time.

Linux provides a limited means to interact with BIOS settings during the boot process (mostly overriding them). In this section, you learn about those commands.

Other options are in the following list, and are more fully outlined in the BOOTPROMPT HOWTO and the kernel documentation. These commands can be used to force the IDE controllers and drives to be optimally configured. However, YMMV (Your Mileage May Vary) because these do not work for everyone.

- `idex=dma`—This will force DMA support to be turned on for the primary IDE bus, where x=0, or the secondary bus, where x=1.
- `idex=autotune`—This command will attempt to tune the interface for optimal performance.
- `hdx=ide-scsi`—This command will enable SCSI emulation of an IDE drive. This is required for some CD-RW drives to work properly in write mode, and it might provide some performance improvements for regular CD-R drives as well.
- `idebus=xx`—This can be any number from 20 to 66; autodetection is attempted, but this can set it manually if `dmesg` says that it isn’t autodetected correctly or if you have it set in the BIOS to a different value (overclocked). Most PCI controllers will be happy with 33.
- pci=biosirq—Some motherboards might cause Linux to generate an error message saying that you should use this. Look in dmesg for it; if you do not see it, you don’t need to use it.

These options can be entered into /etc/lilo.conf or /boot/grub/grub.conf or GRUB2’s /boot/grub/grub.cfg in the same way as other options are appended.

The **hdparm Command**

The `hdparm` utility can be used by root to set and tune the settings for IDE hard drives. You would do this to tune the drives for optimal performance.

Once a kernel patch and associated support programs, the `hdparm` program is now included with Ubuntu. You should only experiment with the file systems mounted read-only because some settings can damage some file systems when used improperly. The `hdparm` command also works with CD-ROM drives and some SCSI drives.

The general format of the command is this:

```
matthew@seymour:~? hdparm command device
```

This command runs a hard disk test:

```
matthew@seymour:~? hdparm -tT /dev/hda
```

You will need to replace `/dev/hda` with the location of your hard disk. `hdparm` will then run two tests—cached reads and buffered disk reads. A good IDE hard disk should be getting 400–500MB/sec for the first test, and 20–30MB/sec for the second. Note your scores, then try this command:

```
matthew@seymour:~? hdparm -m16 -d1 -u1 -c1 /dev/hda
```

That enables various performance-enhancing settings. Now try executing the original command again—if you see an increase, you should run this command:

```
matthew@seymour:~? hdparm -m16 -d1 -u1 -c1 -k1 /dev/hda
```

The extra parameter tells `hdparm` to write the settings to disk so they will be used each time you boot up—ensuring optimal disk performance in the future.

The man entry for `hdparm` is extensive and contains useful detailed information, but because the kernel configuration selected by Ubuntu already attempts to optimize the drives, it might be that little can be gained through tweaking. Because not all hardware combinations can be anticipated by Ubuntu or by Linux, and performance gains are always useful, you’re encouraged to try.

**TIP**

You can use the `hdparm` command to produce a disk transfer speed result with

```
matthew@seymour:~? hdparm -tT device
```

Be aware, however, that although the resulting numbers appear quantitative, they are subject to several technical qualifications beyond the scope of what is discussed and explained in this chapter. Simply put, do not accept values generated by `hdparm` as absolute numbers, but only as a relative measure of performance.
File System Tuning

Never content to leave things alone, Linux provides several tools to adjust and customize the file system settings. The belief is that hardware manufacturers and distribution creators tend to select conservative settings that will work well all the time, leaving some of the potential of your system leashed—that's why you have chosen *Ubuntu Unleashed* to help you.

The Linux file system designers have done an excellent job of selecting default values used for file system creation, and the 2.6 version of the Linux kernel now contains new code for the IDE subsystem that significantly improves I/O (input/output) transfer speeds over older versions, obviating much of the need for special tweaking of the file system and drive parameters if you use IDE disks. Although these values work well for most users, some server applications of Linux benefit from file system tuning. As always, observe and benchmark your changes.

SYNCHRONIZING THE FILE SYSTEM WITH SYNC

Because Linux uses buffers when writing to devices, the write will not occur until the buffer is full, until the kernel tells it to, or if you tell it to by using the `sync` command. Traditionally, the command is given twice, as in the following:

```
matthew@seymour:~? sync ; sync
```

To do it twice is overkill. Still, it can be helpful before the unmounting of certain types of media with slow write speeds (such as some USB hard drives or PCMCIA storage media), but only because it delays the user from attempting to remove the media too soon, not because two syncs are better than one.

The `tune2fs` Command

With `tune2fs`, you can adjust the tunable file system parameters on an ext2 or ext3 file system. A few performance-related items of note are as follows:

- To disable file system checking, the `-c 0` option sets the maximal mount count to zero.
- The interval between forced checks can be adjusted with the `-i` option.
- The `-m` option will set the reserved blocks percentage with a lower value, freeing more space at the expense of `fsck` having less space to write any recovered files.
- Decrease the number of superblocks to save space with the `-O sparse_super` option. (Modern file systems use this by default.) Always run `e2fsck` after you change this value.
- More space can be freed with the `-r` option that sets the number of reserved (for root) blocks.

Note that most of these uses of `tune2fs` free up space on the drive at the expense of the capability of `fsck` to recover data. Unless you really need the space and can deal with the consequences, just accept the defaults; large drives are now relatively inexpensive.
The e2fsck Command

This utility checks an ext2/ext3 file system. Some useful arguments taken from man e2fsck are as follows:

- `-c`—Checks for bad blocks and then marks them as bad.
- `-f`—Forces checking on a clean file system.
- `-v`—Verbose mode.

The badblocks Command

Although not a performance tuning program per se, the utility badblocks checks an (preferably) unmounted partition for bad blocks. It is not recommended that you run this command by itself, but rather allow it to be called by fsck. It should be used directly only if you specify the block size accurately—don’t guess or assume anything.

The options available for badblocks are detailed in the man page. They allow for very low-level manipulation of the file system that is useful for data recovery by file system experts or for file system hacking, but are beyond the scope of this chapter and the average user.

Disabling File Access Time

Whenever Linux reads a file, it changes the last access time—known as the atime. This is also true for your web server: If you are getting hit by 50 requests a second, your hard disk will be updating the atime 50 times a second. Do you really need to know the last time a file was accessed? If not, you can disable the atime setting for a directory by typing this:

```
matthew@seymour:~? chattr –R +A /path/to/directory
```

The chattr command changes file system attributes, of which “don’t update atime” is one. To set that attribute, use +A and specify –R so that it is recursively set. /path/to/directory gets changed, and so do all the files and subdirectories it contains.

Kernel

As the Linux kernel developed over time, developers sought a way to fine-tune some of the kernel parameters. Before sysctl, those parameters had to be changed in the kernel configuration, and then the kernel had to be recompiled.

The sysctl command can change some parameters of a running kernel. It does this through the /proc file system, which is a “virtual window” into the running kernel. Although it might appear that a group of directories and files exist under /proc, that is only a representation of parts of the kernel. When we’re the root user (or using the sudo command), we can read values from and write values to those “files,” referred to as variables. We can display a list of the variables as shown in the following. (An annotated list is presented because roughly 250 items, or more, exist in the full list.)

```
matthew@seymour:~? sysctl -A
net.ipv4.tcp_max_syn_backlog = 1024
```

Download from www.eBookTM.com
net.ipv4.tcp_rfc1337 = 0
net.ipv4.tcp_stdurg = 0
net.ipv4.tcp_abort_on_overflow = 0
net.ipv4.tcp_tw_recycle = 0
net.ipv4.tcp_syncookies = 0
net.ipv4.tcp_fin_timeout = 60
net.ipv4.tcp_retries2 = 15
net.ipv4.tcp_retries1 = 3
net.ipv4.tcp_keepalive_intvl = 75
net.ipv4.tcp_keepalive_probes = 9
net.ipv4.tcp_keepalive_time = 7200
net.ipv4.ipfrag_time = 30

The items shown are networking parameters, and tweaking these values is beyond the scope of this book. If we wanted to change a value, however, the -w parameter is used:

```
matthew@seymour:~? sysctl -w net.ipv4.tcp_retries 2=20
```

This increases the value of that particular kernel parameter.

If you find that a particular setting is useful, you can enter it into the `/etc/sysctl.conf` file. The format is as follows, using the earlier example:

```
net.ipv4.tcp_retries 2=20
```

Of more interest to kernel hackers than regular users, `sysctl` is a potentially powerful tool that continues to be developed and documented.

---

**TIP**

The kernel does a good job of balancing performance for graphical systems, so there's not a great deal you can do to tweak your desktop to run faster.

Both GNOME and KDE are “heavyweight” desktop systems: They are all-inclusive, all-singing, and all-dancing environments that do far more than browse your file system. The drawback is that their size makes them run slow on older systems. On the flip side, Ubuntu has others available in the repositories like the Xfce desktop, which is a great deal slimmer and faster than the other two. If you find GNOME and KDE are struggling just to open a file browser, Xfce is for you.

---

**Apache**

Despite being the most popular web server on the Internet, Apache is by no means the fastest. Part of the “problem” is that Apache has been written to follow every applicable standard to the letter, so much of its development work has been geared toward standards-
compliancy rather than just serving web pages quickly. However, with a little tweaking we can convert an inexpensive middle-of-the-road server into something capable of surviving the Slashdot Effect.

NOTE

Slashdot.org is a popular geek news website that spawned the Slashdot Effect—the result of thousands of geeks descending on an unsuspecting website simultaneously.

The first target for your tuning should be the apache2.conf file in /etc/apache2, as well as the other files in /etc/apache2. The more modules you have loaded, the more load Apache is placing on your server—take a look through the LoadModule list and comment out (start the line with a #) the ones you do not want. Some of these modules can be uninstalled entirely through the Add or Remove Packages dialog.

As a rough guide, you will almost certainly need mod_mime and mod_dir, and probably also mod_log_config. The default Apache configuration in Ubuntu is quite generic, so unless you are willing to sacrifice some functionality you may also need mod_negotiation (a speed killer if there ever was one), and mod_access (a notorious problem). Both of those modules can and should work with little or no performance decrease, but all too often they get abused and just slow things down.

Whatever you do, when you are disabling modules you should ensure that you leave either mod_deflate or mod_gzip enabled, depending on your Apache version. Your bottleneck is almost certainly going to be your bandwidth rather than your processing power, and having one of these two compressing your content will usually turn 10KB of HTML into 3KB for supported browsers (most of them).

Next, ensure keepalives are turned off. Yes, you read that right: turn keepalives off. This adds some latency to people viewing your site, because they cannot download multiple files through the same connection. However, it reduces the number of simultaneous open connections and so allows more people to connect.

If you are serving content that does not change, you can take the extreme step of enabling MMAP support. This allows Apache to serve pages directly from RAM without bothering to check whether they have changed, which works wonders for your performance. However, the downside is that when you do change your pages you need to restart Apache. Look for the EnableMMAP directive—it is probably commented out and set to off, so you will need to remove the comment and set it to on.

Finally, you should do all you can to ensure that your content is static: avoid PHP if you can, avoid databases if you can, and so on. If you know you are going to get hit by a rush of visitors, use plain HTML so that Apache is limited only by your bandwidth for how fast it can serve pages.
TIP

Some people, when questioned about optimizing Apache, will recommend you tweak the HARD_SERVER_LIMIT in the Apache source code and recompile. While we agree that compiling your own Apache source code is a great way to get a measurable speed boost if you know what you are doing, you should need to change this directive only if you are hosting a huge site. The default value, 256, is enough to handle the Slashdot effect, and if you can handle that then you can handle most things.

MySQL

Tuning your MySQL server for increased performance is exceptionally easy to do, largely because you can see huge speed increases simply by getting your queries right. However, you can tune various things in the server itself to help it cope with higher loads as long as your system has enough RAM.

The key is understanding its buffers—there are buffers and caches for all sorts of things, and finding out how full they are is crucial to maximizing performance. MySQL performs best when it is making full use of its buffers, which in turn places a heavy demand on system RAM. Unless you have 4GB RAM or more in your machine, you do not have enough capacity to set very high values for all your buffers—you need to pick and choose.

Measuring Key Buffer Usage

When you add indexes to your data, it enables MySQL to find data faster. However, ideally you want to have these indexes stored in RAM for maximum speed, and the variable key_buffer_size defines how much RAM MySQL can allocate for index key caching. If MySQL cannot store its indexes in RAM, you will experience serious performance problems. Fortunately, most databases have relatively small key buffer requirements, but you should measure your usage to see what work needs to be done.

To do this, log in to MySQL and type SHOW STATUS LIKE '%key_read%'; That returns all the status fields that describe the hit rate of your key buffer—you should get two rows back: Key_reads and Key_read_requests, which are the number of keys being read from disk and the number of keys being read from the key buffer. From these two numbers you can calculate the percentage of requests being filled from RAM and from disk, using this simple equation:

$$100 - \left(\frac{\text{Key}\_\text{reads}}{\text{Key}\_\text{read}\_\text{requests}}\right) \times 100$$

That is, you divide Key_reads by Key_read_requests, multiply the result by 100 and then subtract the result from 100. For example, if you have Key_reads of 1000 and Key_read_requests of 100000, you divide 1000 by 100000 to get 0.01; then you multiply that by 100 to get 1.0, and subtract that from 100 to get 99. That number is the percentage of key reads being served from RAM, which means 99 percent of your keys are served from RAM.
Most people should be looking to get more than 95 percent served from RAM, although the primary exception is if you update or delete rows very often—MySQL can’t cache what keeps changing. If your site is largely read-only, this should be around 98 percent. Lower figures mean you might need to bump up the size of your key buffer.

If you are seeing problems, the next step is to check how much of your current key buffer is being used. Use the `SHOW VARIABLES` command and look up the value of the `key_buffer_size` variable. It is probably something like 8388600, which is eight million bytes, or 8MB. Now, use the `SHOW STATUS` command and look up the value of `Key_blocks_used`.

You can determine how much of your key buffer is being used by multiplying `Key_blocks_used` by 1024, dividing by `key_buffer_size`, and multiplying by 100. For example, if `Key_blocks_used` is 8000, multiply that by 1024 to get 8192000; then divide that by your `key_buffer_size` (8388600) to get 0.97656, and finally multiply that by 100 to get 97.656. Thus, almost 98 percent of your key buffer is being used.

Now, the important part: You have ascertained that you are reading lots of keys from disk, and you also know that the reason for reading from disk is almost certainly because you do not have enough RAM allocated to the key buffer. A general rule is to allocate as much RAM to the key buffer as you can, up to a maximum of 25 percent of system RAM—128MB on a 512MB system is about the ideal for systems that read heavily from keys. Beyond that, you will actually see drastic performance decreases because the system has to use virtual memory for the key buffer.

Open `/etc/my.cnf` in your text editor, and look for the line that contains `key_buffer_size`. If you do not have one, you need to create a new one—it should be under the line `[mysqld]`. When you set the new value, do not just pick some arbitrarily high number. Try doubling what is there right now (or try 16MB if there’s no line already); then see how it goes. To set 16MB as the key buffer size, you would need a line like this:

```
[mysqld]
set-variable = key_buffer_size=16M
datadir=/var/lib/mysql
```

Restart your MySQL server with service `mysqld` restart, and then go back into MySQL and run `SHOW VARIABLES` again to see the `key_buffer_size`. It should be 16773120 if you have set it to 16M. Now, because MySQL just got reset, all its values for key hits and the like will also have been reset. You need to let it run for a while so you can assess how much has changed. If you have a test system you can run, this is the time to run it.

After your database has been accessed with normal usage for a short while (if you get frequent accesses, this might be only a few minutes), recalculate how much of the key buffer is being used. If you get another high score, double the size again, restart, and retest. You should keep repeating this until your key buffer usage is below 50 percent or you find you don’t have enough RAM to increase the buffer further—remember that you should never allocate more than 25 percent of system RAM to the key buffer.
Using the Query Cache

Newer versions of MySQL allow you to cache the results of queries so that, if new queries come in that use the same SQL, the result can be served from RAM. In some ways the query cache is quite intelligent: If, for example, part of the result changes due to another query, the cached results are thrown away and recalculated next time. However, in other ways it is very simple. For example, it uses cached results only if the new query is exactly the same as a cached query, even down to the capitalization of the SQL.

The query cache works well in most scenarios. If your site has an equal mix of reading and writing, the query cache will do its best but will not be optimal. If your site is mostly reading with few writes, more queries will be cached (and for longer), thus improving overall performance.

First, you need to find out whether you have the query cache enabled. To do this, use `SHOW VARIABLES` and look up the value of `have_query_cache`. All being well, you should get `YES` back, meaning that the query cache is enabled. Next, look for the value of `query_cache_size` and `query_cache_limit`. The first is how much RAM in bytes is allocated to the query cache, and the second is the maximum result size that should be cached. A good starting set of values for these two is 8388608 (8MB) and 1048576 (1MB).

Next, type `SHOW STATUS LIKE 'Qcache%';` to see all the status information about the query cache. You should get output like this:

```sql
mysql> SHOW STATUS LIKE 'qcache%';
+----------------------------+----------+
| Variable_name              | Value    |
+----------------------------+----------+
| Qcache_free_blocks         | 1        |
| Qcache_free_memory         | 169544   |
| Qcache_hits                | 698      |
| Qcache_inserts             | 38       |
| Qcache_lowmem_prunes       | 20       |
| Qcache_not_cached          | 0        |
| Qcache_queries_in_cache    | 18       |
| Qcache_total_blocks        | 57       |
+----------------------------+----------+
8 rows in set (0.00 sec)
```

From that, we can see that only 18 queries are in the cache (`Qcache_queries_in_cache`); we have 169544 bytes of memory free in the cache (`Qcache_free_memory`), 698 queries have been read from the cache (`Qcache_hits`), 38 queries have been inserted into the cache (`Qcache_inserts`), but 20 of them were removed due to lack of memory (`Qcache_lowmem_prunes`), giving the 18 from before. `Qcache_not_cached` is 0, which means 0 queries were not cached—MySQL is caching them all.

From that, we can calculate how many total queries came in—it is the sum of `Qcache_hits`, `Qcache_inserts`, and `Qcache_not_cached`, which is 736. We can also calcu-
late how well the query cache is being used by dividing Qcache_hits by that number and multiplying by 100. In this case, 94.84 percent of all queries are being served from the query cache, which is a great number.

In our example, we can see that many queries have been trimmed because there is not enough memory in the query cache. This can be changed by editing your /etc/my.cnf file and adding a line like this one, somewhere in the [mysqld] section:

```
set-variable = query_cache_size=32M
```

An 8MB query cache should be enough for most people, but larger sites might need 16MB or even 32MB if you are storing a particularly large amount of data. Very few sites will need to go beyond a 32MB query cache, but keep an eye on the Qcache_lowmem_prunes value to ensure you have enough RAM allocated.

Using the query cache does not incur much of a performance hit. When MySQL calculates the result of a query normally, it throws it away when the connection closes. With the query cache, it skips the throwing away, and so there is no extra work being done. If your site does have many updates and deletes, be sure to check whether you get any speed boost at all from the query cache.

**Miscellaneous Tweaks**

If you have tuned your key buffer and optimized your query cache and yet still find your site struggling, you can make a handful of smaller changes that will add some more speed.

When reading from tables, MySQL has to open the file that stores the table data. How many files it keeps open at a time is defined by the table_cache setting, which is set to 64 by default. You can increase this setting if you have more than 64 tables, but you should be aware that Ubuntu imposes limits on MySQL about how many files it can have open at a time. Going beyond 256 is not recommended unless you have a particularly DB-heavy site and know exactly what you are doing.

The other thing you can tweak is the size of the read buffer, which is controlled by read_buffer_size and read_buffer_rnd_size. Both of these are allocated per connection, which means you should be very careful to have large numbers. Whatever you choose, read_buffer_rnd_size should be three to four times the size of read_buffer_size, so if read_buffer_size is 1MB (suitable for very large databases), read_buffer_rnd_size should be 4MB.

**Query Optimization**

The biggest speed-ups can be seen by reprogramming your SQL statements so they are more efficient. If you follow these tips, your server will thank you:

- Select as little data as possible. Rather than SELECT *, select only the fields you need.
- If you need only a few rows, use LIMIT to select the number you need.
- Declare fields as NOT NULL when creating tables to save space and increase speed.
- Provide default values for fields, and use them where you can.
Be very careful with table joins because they are the easiest way to write inefficient queries.

If you must use joins, be sure you join on fields that are indexed. They should also preferably be integer fields, because these are faster than strings for comparisons.

Find and fix slow queries. Add `log-long-format` and `log-slow-queries = /var/log/slow-queries.log` to your `/etc/my.cnf` file, under `[mysqld]`, and MySQL will tell you the queries that took a long time to complete.

Use `OPTIMIZE TABLE tablename` to defragment tables and refresh the indexes.

Some Linux users like to focus on the graphical environments that are available—they rush to tell new users that the command line isn’t vital when using Linux. Although there are some amazing GUI desktops and this statement is mostly true, avoiding the command line limits your options and makes some tasks more difficult. The command-line interface is where the greatest power and flexibility are found, and those who actively avoid learning how to use it are also actively limiting their abilities and options. You learned the basics earlier in Chapter 4, “Command Line Quickstart.” In this chapter we will dig in deeper.

In his book *The Art of Unix Programming*, Eric Raymond wrote a short story that perfectly illustrates the power of the command line versus the GUI. It’s reprinted here with permission, for your reading pleasure:

One evening, Master Foo and Nubi attended a gathering of programmers who had met to learn from each other. One of the programmers asked Nubi to what school he and his master belonged. Upon being told they were followers of the Great Way of Unix, the programmer grew scornful.

“The command-line tools of Unix are crude and backward,” he scoffed.

“Modern, properly designed operating systems do everything through a graphical user interface.”

Master Foo said nothing, but pointed at the moon. A nearby dog began to bark at the master’s hand.

“I don’t understand you!” said the programmer.

Master Foo remained silent, and pointed at an image of the Buddha. Then he pointed at a window.
“What are you trying to tell me?” asked the programmer.
Master Foo pointed at the programmer’s head. Then he pointed at a rock.
“Why can’t you make yourself clear?” demanded the programmer.
Master Foo frowned thoughtfully, tapped the programmer twice on the nose, and dropped him in a nearby trash can.

As the programmer was attempting to extricate himself from the garbage, the dog wandered over and piddled on him.

At that moment, the programmer achieved enlightenment.

Whimsical as the story is, it does illustrate that there are some things that the GUI just does not do well. Enter the command line: It is a powerful and flexible operating environment and—if you practice—can actually be quite fun, too!

In this chapter, you will learn how to master the command line so that you are able to perform common tasks through it, and also link commands together to create new command groups. We will also be looking at the two most popular Linux text editors: Vim and Emacs. The command line is also known as the shell, the console, the command prompt, and the command-line interpreter (CLI). For the purposes of this chapter, these are interchangeable, although fine-grained differences exist between them!

**Why Use the Shell?**

Moving from the GUI to the command line is a conscious choice for most people, although it is increasingly rare that it is an either choice. While using a graphical desktop on top of the X server, you can press Ctrl+Alt+F1 (or any of F2 to F6) at any time to switch to a terminal, but most people tend to run an X terminal application that allows them to have the point-and-click applications and the command-line applications side by side, such as the default one found in the menu at Applications, Accessories, Terminal.

Reasons for running the shell include the following:

- You want to chain two or more commands together.
- You want to use a command or parameter available only on the shell.
- You are working on a text-only system.
- You have used it for a long time and feel comfortable there.

Chaining two or more commands together, or piping, is what gives the shell its real power. Hundreds of commands are available and, by combining them in different ways, you get tons of new options. Some of the shell commands are available through the GUI, but these commands usually have only a small subset of their parameters available, which limits what you are able to do with them.

Working from a text-only system is also useful both for working locally with a broken GUI and also for connecting to a remote, text-only system. If your Linux server is experiencing problems, the last thing you want to do is load it down with a GUI connection—working in text mode is faster and more efficient.
The last use is probably the most common: many people use the shell simply because it is familiar to them. Some people even use the shell to start GUI applications just because it saves them taking their hands off the keyboard for a moment! This is not a bad thing; it provides fluency and ease with the system and is a perfectly valid way of working. Working from the command line is faster. The mouse is slow and taking your fingers away from the keyboard makes your work even slower. Anyone looking to achieve the zen-like power-user state hinted at by Eric Raymond will understand this after making the effort to learn.

**Basic Commands**

It is impossible to know how many commands the average shell citizen uses, but if we had to guess, we would place it at about 25:

- *cat*—Prints the contents of a file
- *cd*—Changes directories
- *chmod*—Changes file access permissions
- *cp*—Copies files
- *du*—Prints disk usage
- *emacs*—Text editor
- *find*—Finds files by searching
- *gcc*—The C/C++/Fortran compiler
- *grep*—Searches for a string in input
- *less*—Filter for paging through output
- *ln*—Creates links between files
- *locate*—Finds files from an index
- *ls*—Lists files in the current directory
- *make*—Compiles and installs programs
- *man*—The manual page reader
- *mkdir*—Makes directories
- *mv*—Moves files
- *ps*—Lists processes
- *rm*—Deletes files and directories
- *ssh*—Connects to other machines
- *tail*—Prints the last lines of a file
- *top*—Prints resource usage
Many other commands also are available to you that get used fairly often—diff, gzip, history, ping, su, tar, uptime, who, and so on—but if you are able to understand the 25 listed here, you will have sufficient skill to concoct your own command combinations.

Note that we say understand the commands—not know all their possible parameters and usages. This is because several of the commands, though commonly used, are used only in any complex manner by people with specific needs. gcc and make are good examples of this: Unless you plan to become a programmer, you need not worry about these beyond just typing make and make install now and then. If you want to learn more about these two, see Chapter 30, “C/C++ Programming Tools for Ubuntu.”

Similarly, both Emacs and Vim are text editors that have a text-based interface all of their own, and SSH has already been covered in detail in Chapter 15, “Remote Access with SSH and Telnet.”

What remains is 20 commands, each of which has many parameters to customize what it actually does. Again, we can eliminate much of this because many of the parameters are esoteric and rarely used, and, the few times in your Linux life that you need them, you can just read the manual page.

We will be going over these commands one by one, explaining the most common ways to use them. There is one exception: The xargs command requires you to understand how to join commands together.

**Printing the Contents of a File with cat**

Many of Ubuntu’s shell commands manipulate text strings, so if you want to be able to feed them the contents of files, you need to be able to output those files as text. Enter the cat command, which prints the contents of any files you pass to it.

Its most basic use is like this:

```bash
matthew@seymour:~$ cat myfile.txt
```

That prints the contents of `myfile.txt`. For this usage there are two extra parameters that are often used: `-n` numbers the lines in the output, and `-s` (“squeeze”) prints a maximum of one blank line at a time. That is, if your file has 1 line of text, 10 blank lines, 1 line of text, 10 blank lines, and so on, `-s` shows the first line of text, a single blank line, the next line of text, a single blank line, and so forth. When you combine `-s` and `-n`, cat numbers only the lines that are printed—the 10 blank lines shown as one will count as 1 line for numbering.

This command prints information about your CPU, stripping out multiple blank lines and numbering the output:

```bash
matthew@seymour:~$ cat -sn /proc/cpuinfo
```
You can also use `cat` to print the contents of several files at once, like this:

```
matthew@seymour:~$ cat -s myfile.txt myotherfile.txt
```

In that command, `cat` merges `myfile.txt` and `myotherfile.txt` on the output, stripping out multiple blank lines. The important thing is that `cat` does not distinguish between the files in the output—there are no filenames printed, and no extra breaks between the 2. This allows you to treat the 2 as 1 or, by adding more files to the command line, to treat 20 files as 1.

### Changing Directories with `cd`

Changing directories is surely something that has no options, right? Not so. `cd` is actually more flexible than most people realize. Unlike most of the other commands here, `cd` is not a command in itself—it is built in to `bash` (or whichever shell interpreter you are using), but it is still used like a command.

The most basic usage of `cd` is this:

```
matthew@seymour:~$ cd somedir
```

That looks in the current directory for the `somedir` subdirectory, then moves you into it. You can also specify an exact location for a directory, like this:

```
matthew@seymour:~$ cd /home/matthew/stuff/somedir
```

The first part of `cd`’s magic lies in the characters (- and ~, a dash and a tilde). The first means “switch to my previous directory,” and the second means “switch to my home directory.” This conversation with `cd` shows this in action:

```
matthew@seymour:~$ cd /usr/local
matthew@seymour/usr/local$ cd bin
matthew@seymour/usr/local/bin$ cd -
/usr/local
matthew@seymour/usr/local$ cd ~
matthew@seymour:~$
```

In the first line, we change to `/usr/local` and get no output from the command. In the second line, we change to `bin`, which is a subdirectory of `/usr/local`. Next, `cd -` is used to change back to the previous directory. This time Bash prints the name of the previous directory so we know where we are. Finally, `cd ~` is used to change back to our home directory, although if you want to save an extra few keystrokes, just typing `cd` by itself is equivalent to `cd ~`.

The second part of `cd`’s magic is its capability to look for directories in predefined locations. When you specify an absolute path to a directory (that is, one starting with a `/`), `cd` always switches to that exact location. However, if you specify a relative subdirectory—for example, `cd subdir`—you can tell `cd` where you would like that to be relative to. This is accomplished with the `CDPATH` environment variable. If this variable is not set, `cd` always uses the current directory as the base; however, you can set it to any number of other directories.
This next example shows a test of this. It starts in `/home/matthew/empty`, an empty directory, and the lines are numbered for later reference:

```bash
1 matthew@seymour:~/empty$ pwd
2 /home/matthew/empty
3 matthew@seymour:~/empty$ ls
4 matthew@seymour:~/empty$ mkdir local
5 matthew@seymour:~/empty$ ls
6 local
7 matthew@seymour:~/empty$ cd local
8 matthew@seymour:~/empty$ cd ..
9 matthew@seymour:~/empty$ export CDPATH=/usr
10 matthew@seymour:~/empty$ cd local
11 /usr/local
12 matthew@seymour:/usr/local$ cd -
13 /home/matthew/empty
14 matthew@seymour:~/empty$ export CDPATH=.:usr
15 matthew@seymour:~/empty$ cd local
16 /home/matthew/empty/local
17 matthew@seymour:~/empty/local$
```

Lines 1–3 show that we are in `/home/matthew/empty` and that it is indeed empty—`ls` had no output. Lines 4–6 show the `local` subdirectory being made, so that `/home/matthew/empty/local` exists. Lines 7 and 8 show you can `cd` into `/home/matthew/empty/local` and back out again.

In line 9, `CDPATH` is set to `/usr`. This was chosen because Ubuntu has the directory `/usr/local`, which means our current directory (`/home/matthew/empty`) and our `CDPATH` directory (`/usr`) both have a local subdirectory. In line 10, while in the `/home/matthew/empty` directory, we use `cd local`. This time, Bash switches us to `/usr/local` and even prints the new directory to ensure we know what it has done.

Lines 12 and 13 move us back to the previous directory, `/home/matthew/empty`. In line 14, `CDPATH` is set to be `.:usr`. The `:` is the directory separator, so this means Bash should look first in the current directory, `.`, and then in the `/usr` directory. In line 15 `cd local` is issued again, this time moving to `/home/matthew/empty/local`. Note that Bash has still printed the new directory—it does that whenever it looks up a directory in `CDPATH`.

### Changing File Access Permissions with `chmod`

Your use of `chmod` can be greatly extended through one simple parameter: `-c`. This instructs `chmod` to print a list of all the changes it made as part of its operation, which means we can capture the output and use it for other purposes. For example:

```bash
matthew@seymour:~$ chmod -c 600 *
mode of '1.txt' changed to 0600 (rw------)
mode of '2.txt' changed to 0600 (rw------)
mode of '3.txt' changed to 0600 (rw------)
matthew@seymour:~$ chmod -c 600 *
```

There the `chmod` command is issued with `-c`, and you can see it has output the result of the operation: Three files were changed to `rw------` (read and write by user only). However, when the command is issued again, no output is returned. This is because `-c` prints only
the changes that it made. Files that already match the permissions you are setting are left unchanged and therefore are not printed.

There are two other parameters of interest: --reference and -R. The first allows you to specify a file to use as a template for permissions rather than specifying permissions yourself. For example, if you want all files in the current directory to have the same permissions as the file /home/matthew/myfile.txt, you would use this:

```
chmod --reference /home/matthew/myfile.txt *
```

You can use -R to enable recursive operation, which means you can use it to chmod a directory and it will change the permissions of that directory as well as all files and subdirectories under that directory. You could use `chmod -R 600 /home` to change every file and directory under /home to become read/write to their owner.

### Copying Files with cp

Like mv, which is covered later, cp is a command that is easily used and mastered. However, two marvelous parameters rarely see much use (which is a shame!) despite their power. These are --parents and -u. The first copies the full path of the file into the new directory; the second copies only if the source file is newer than the destination.

Using --parents requires a little explanation, so here is an example. You have a file, /home/matthew/desktop/documents/work/notes.txt, and want to copy it to your /home/matthew/backup folder. You could do a normal cp, but that would give you /home/matthew/backup/notes.txt, so how would you know where that came from later? If you use --parents, the file is copied to /home/matthew/backup/desktop/documents/work/notes.txt.

The -u parameter is perfect for synchronizing two directories because it allows you to run a command like `cp -Ru myfiles myotherfiles` and have cp recopy only files that have changed. The -R parameter means recursive and allows you to copy directory contents.

### Printing Disk Usage with du

The du command prints the size of each file and directory that is inside the current directory. Its most basic usage is as easy as it gets:

```
matthew@seymour:~$ du
```

That outputs a long list of directories and how much space their files take up. You can modify that with the -a parameter, which instructs du to print the size of individual files as well as directories. Another useful parameter is -h, which makes du use human-readable sizes like 18M (18MB) rather than 17532 (the same number in bytes, unrounded). The final useful basic option is -c, which prints the total size of files.

So, using du we can get a printout of the size of each file in our home directory, in human-readable format, and with a summary at the end, like this:

```
matthew@seymour:~$ du -ahc /home/matthew
```
Two advanced parameters deal with filenames you want excluded from your count. The first is --exclude, which allows you to specify a pattern that should be used to exclude files. This pattern is a standard shell file matching pattern as opposed to a regular expression, which means you can use ? to match a single character or * to match 0 or many characters. You can specify multiple --exclude parameters to exclude several patterns. For example:

```
matthew@seymour:~$ du --exclude="*.xml" --exclude="*.xsl"
```

However, typing numerous --exclude parameters repeatedly is a waste of time, so you can use -X to specify a file that has the list of patterns you want excluded. The file should look like this:

```
*.xml
*.xsl
```

That is, each pattern you want excluded should be on a line by itself. If that file were called xml_exclude.txt, we could use it in place of the previous example, like this:

```
matthew@seymour:~$ du -X xml_exclude.txt
```

You can make your exclusion file as long as you need, or you can just specify multiple -X parameters.

---

**TIP**

Running du in a directory where several files are hard-linked to the same inode counts the size of the file only once. If you want to count each hard link separately for some reason, use the -l parameter (lowercase L).

---

**Finding Files by Searching with find**

The `find` command is one of the darkest and least understood areas of Linux, but it is also one of the most powerful. Admittedly, the `find` command does not help itself by using X-style parameters. The UNIX standard is -c, -s, and so on, whereas the GNU standard is — dosomething, —mooby, and so forth. X-style parameters merge the two by having words preceded by only one dash.

However, the biggest problem with `find` is that it has more options than most people can remember—it truly is capable of doing most things you could want. The most basic usage is this:

```
matthew@seymour:~$ find -name "*.txt"
```

That searches the current directory and all subdirectories for files that end in .txt. The previous search finds files ending in .txt but not .TXT, .Txt, or other case variations. To
search without case sensitivity, use -iname instead of -name. You can optionally specify where the search should start before the -name parameter, like this:

matthew@seymour:~$ find /home -name "*.txt"

Another useful test is -size, which lets you specify how big the files should be to match. You can specify your size in kilobytes and optionally use + or - to specify greater than or less than. For example:

matthew@seymour:~$ find /home -name "*.txt" -size 100k
matthew@seymour:~$ find /home -name "*.txt" -size +100k
matthew@seymour:~$ find /home -name "*.txt" -size -100k

The first brings up files of exactly 100KB, the second only files larger than 100KB, and the last only files under 100KB.

Moving on, the -user option enables you to specify the user who owns the files you are looking for. So, to search for all files in /home that end with .txt, that are under 100KB, and that are owned by user matthew, you would use this:

matthew@seymour:~$ find /home -name "*.txt" -size -100k -user matthew

You can flip any of the conditions by specifying -not before them. For example, you can add a -not before -user matthew to find matching files owned by everyone but matthew:

matthew@seymour:~$ find /home -name "*.txt" -size -100k -not -user matthew

You can add as many -not parameters as you need, even using -not -not to cancel each other out! (Yes, that is pointless.) Keep in mind, though, that -not -size -100k is essentially equivalent to -size +100k, with the exception that the former will match files of exactly 100KB whereas the latter will not.

You can use -perm to specify which permissions a file should have for it to be matched. This is tricky, so read carefully. The permissions are specified in the same way as with the chmod command: u for user, g for group, o for others, r for read, w for write, and x for execute. However, before you give the permissions, you need to specify either a plus, a minus, or a blank space. If you specify neither a plus nor a minus, the files must exactly match the mode you give. If you specify -, the files must match all the modes you specify. If you specify +, the files must match any the modes you specify. Confused yet?

The confusion can be cleared up with some examples. This next command finds all files that have permission o=r (readable for other users). Notice that if you remove the -name parameter, it is equivalent to * because all filenames are matched.

matthew@seymour:~$ find /home -perm -o=r

Any files that have o=r set are returned from that query. Those files also might have u=rw and other permissions, but as long as they have o=r, they will match. This next query matches all files that have o=rw set:

matthew@seymour:~$ find /home -perm -o=rw

However, that query does not match files that are o=r or o=w. To be matched, a file must be readable and writable by other users. If you want to match readable or writable (or both), you need to use +, like this:

matthew@seymour:~$ find /home -perm +o=rw

Download from www.eBookTM.com
Similarly, this next query matches only files that are readable by user, group, and others:

```
matthew@seymour:~$ find /home -perm -ugo=r
```

Whereas this query matches files as long as they are readable by the user, or by the group, or by others, or by any combination of the three:

```
matthew@seymour:~$ find /home -perm +ugo=r
```

If you use neither + or -, you are specifying the exact permissions to search for. For example, the next query searches for files that are readable by user, group, and others but not writeable or executable by anyone:

```
matthew@seymour:~$ find /home -perm ugo=r
```

You can be as specific as you need to be with the permissions. For example, this query finds all files that are readable for the user, group, and others and writeable by the user:

```
matthew@seymour:~$ find /home -perm ugo=r,u=w
```

To find files that are not readable by others, use the `-not` condition, like this:

```
matthew@seymour:~$ find /home -not -perm +o=r
```

Now, on to the most advanced aspect of the find command: the `-exec` parameter. This enables you to execute an external program each time a match is made, passing in the name of the matched file wherever you want it. This has very specific syntax: Your command and its parameters should follow immediately after `-exec`, terminated by `\;`. You can insert the filename match at any point using `{}` (an opening and a closing brace side by side).

So, you can match all text files on the entire system (that is, searching recursively from `/` rather than from `/home` as in our previous examples) over 10KB, owned by `matthew`, that are not readable by others, and then use `chmod` to enable reading, like this:

```
matthew@seymour:~$ find / -name "*.txt" -size +10k -user matthew -not -perm +o=r -exec chmod o+r {} \;
```

When you type your own `-exec` parameters, be sure to include a space before `\;`. Otherwise, you might see an error such as `missing argument to `-exec'`.

Do you see now why some people think the `find` command is scary? Many people learn just enough about `find` to be able to use it in a very basic way, but hopefully you will see how much it can do if you give it chance.

**Searches for a String in Input with `grep`**

The `grep` command, like `find`, is an incredibly powerful search tool in the right hands. Unlike `find`, though, `grep` processes any text, whether in files, or just in standard input.

The basic usage of `grep` is this:

```
matthew@seymour:~$ grep "some text" *
```

That searches all files in the current directory (but not subdirectories) for the string `some text` and prints matching lines along with the name of the file. To enable recursive searching in subdirectories, use the `-r` parameter, like this:

```
matthew@seymour:~$ grep -r "some text" *
```

Each time a string is matched within a file, the filename and the match are printed. If a file contains multiple matches, each of the matches is printed. You can alter this behavior.
with the -l parameter (lowercase L), which forces grep to print the name of each file that contains at least one match, without printing the matching text. If a file contains more than one match, it is still printed only once. Alternatively, the -c parameter prints each filename that was searched and includes the number of matches at the end, even if there were no matches.

You have a lot of control when specifying the pattern to search for. You can, as we did previously, specify a simple string like some text, or you can invert that search by specifying the -v parameter. For example, this returns all the lines of the file myfile.txt that do not contain the word hello:

```
matthew@seymour:~$ grep -v "hello" myfile.txt
```

You can also use regular expressions for your search term. For example, you can search myfile.txt for all references to cat, sat, or mat with this command:

```
matthew@seymour:~$ grep "\[cms\]at" myfile.txt
```

Adding the -i parameter to that removes case sensitivity, matching Cat, CAT, MaT, and so on:

```
matthew@seymour:~$ grep -i \[cms\]at myfile.txt
```

The output can also be controlled to some extent with the -n and --color parameters. The first tells grep to print the line number for each match, which is where it appears in the source file. The --color parameter tells grep to color the search terms in the output, which helps them stand out when among all the other text on the line. You choose which color you want using the GREP_COLOR environment variable: export GREP_COLOR=36 gives you cyan, and export GREP_COLOR=32 gives you lime green.

This next example uses these two parameters to number and color all matches to the previous command:

```
matthew@seymour:~$ grep -in --color \[cms\]at myfile.txt
```

Later you will see how important grep is for piping with other commands.

**Paging Through Output with less**

The less command enables you to view large amounts of text in a more convenient way than the cat command. For example, your /etc/passwd file is probably more than a screen long, so if you run cat /etc/passwd, you are not able to see what the lines at the top were. Using less /etc/passwd enables you to use the cursor keys to scroll up and down the output freely. Type q to quit and return to the shell.

On the surface, less sounds like a very easy command; however, it has the infamy of being one of the few Linux commands that have a parameter for every letter of the alphabet. That is, -a does something, -b does something else, -c, -d, -e ... -x, -y, -z—they all do things, with some letters even differentiating between upper- and lowercase. Furthermore, these parameters are only used when invoking less. After you are viewing your text, even more commands are available. Make no mistake—less is a complex beast to master.

Input to less can be divided into two categories: what you type before running less and what you type while running it. The former category is easy, so we shall start there.

We have already discussed how many parameters less is capable of taking, but they can be distilled down to three that are very useful: -M, -N, and +. Adding -M (this is different
from -m!) enables verbose prompting in less. Rather than just printing a colon and a flashing cursor, less prints the filename, the line numbers being shown, the total number of lines, and the percentage of how far you are through the file. Adding -N (again, this is different from -n) enables line numbering.

The last option, +, allows you to pass a command to less for it to execute as it starts. To use this, you first need to know the commands available to you in less, which means we need to move to the second category of less input: what you type while less is running.

The basic navigation keys are the up, down, left, and right cursors; Home and End (for navigating to the start and end of a file); and Page Up and Page Down. Beyond that, the most common command is /, which initiates a text search. You type what you want to search for and press Enter to have less find the first match and highlight all subsequent matches. Type / again and press Enter to have less jump to the next match. The inverse of that is ?, which searches backward for text. Type ?, enter a search string, and press Enter to go to the first previous match of that string, or just use ? and press Enter to go to the next match preceding the current position. You can use / and ? interchangeably by searching for something with / and then using ? to go backward in the same search.

Searching with / and ? is commonly used with the + command-line parameter from earlier, which passes less a command for execution after the file has loaded. For example, you can tell less to load a file and place the cursor at the first match for the search hello, like this:

```
matthew@seymour:~$ less +/hello myfile.txt
```

Or, to place the cursor at the last match for the search hello:

```
matthew@seymour:~$ less +?hello myfile.txt
```

Beyond the cursor keys, the controls primarily involve typing a number and then pressing a key. For example, to go to line 50 you type 50g, or to go to the 75 percent point of the file you type 75p. You can also place invisible mark points through the file by pressing m and then typing a single letter. Later, while in the same less session, you can press ’ (a single quote) and then type the letter, and it will move you back to the same position. You can set up to 52 marks, named a–z and A–Z.

One clever feature of less is that you can, at any time, press v to have your file opened inside your text editor. This defaults to Vim, but you can change that by setting the EDITOR environment variable to something else.

If you have made it this far, you can already use less better than most users. You can, at this point, justifiably skip to the next section and consider yourself proficient with less. However, if you want to be a less guru, there are two more things to learn: how to view multiple files simultaneously and how to run shell commands.

Like most other file-based commands in Linux, less can take several files as its parameters. For example:

```
matthew@seymour:~$ less -MN 1.txt 2.txt 3.txt
```
That loads all three files into `less`, starting at `1.txt`. When viewing several files, `less` usually tells you which file you are in, as well as numbering them: `1.txt (file 1 of 3)` should be at the bottom of the screen. However, certain things will make that go away, so you should use `-M` anyway.

You can navigate between files by typing a colon and then pressing `n` to go to the next file or press `p` to go to the previous file; these are referred to from now on as `:n` and `:p`. You can open another file for viewing by typing `:e` and providing a filename. This can be any file you have permission to read, including files outside the local directory. Use Tab to complete filenames. Files you open in this way are inserted one place after your current position, so if you are viewing file 1 of 4 and open a new file, the new file is numbered 2 of 5 and is opened for viewing straight away. To close a file and remove it from the list, use `:d`.

Viewing multiple files simultaneously has implications for searching. By default, `less` searches within only one file, but it is easy to search within all files. When you type `/` or `?` to search, follow it with a `*`—you should see `EOF-ignore` followed by a search prompt. You can now type a search and it will search in the current file; if nothing is found, it looks in subsequent files until it finds a match. Repeating searches is done by pressing `Esc` and then either `n` or `N`. The lowercase option repeats the search forward across files, and the uppercase repeats it backward.

The last thing you need to know is that you can get to a shell from `less` and execute commands. The simplest way to do this is just to type `!` and press Enter. This launches a shell and leaves you free to type all the commands you want, as per normal. Type `exit` to return to `less`. You can also type specific commands by entering them after the exclamation mark, using the special character `%` for the current filename. For example, `du -h %` prints the size of the current file. Finally, you can use `!!` to repeat the previous command.

**Creating Links Between Files with ln**

Linux allows you to create links between files that look and work like normal files for the most part. Moreover, it allows you to make two types of links, known as hard links and symbolic links (symlinks). The difference between the two is crucial, although it might not be obvious at first.

Each filename on your system points to what is known as an inode, which is the absolute location of a file. Linux allows you to point more than one filename to a given inode, and the result is a hard link—two filenames pointing to the same file. Each of these files shares the same contents and attributes. So, if you edit one, the other changes because they are both the same file.

On the other hand, a symlink—sometimes called a soft link—is a redirect to the real file. When a program tries to read from a symlink, it automatically is redirected to what the symlink is pointing at. The fact that symlinks are really just dumb pointers has two advan-
Both types of links have their uses. Creating a hard link is a great way to back up a file on the same disk. For example, if you delete the file in one location, it still exists untouched in the other location. Symlinks are popular because they allow a file to appear to be in a different location; you could store your website in `/var/www/live` and an under-construction holding page in `/var/www/construction`. Then you could have Apache point to a symlink `/var/www/html` that is redirected to either the live or construction directory, depending on what you need.

**TIP**

The `shred` command overwrites a file’s contents with random data, allowing for safe deletion. Because this directly affects a file’s contents, rather than just a filename, this means that all filenames hard linked to an inode are affected.

Both types of link are created using the `ln` command. By default, it creates hard links, but you can create symlinks by passing it the `-s` parameter. The syntax is `ln [-s] <something> <somewhere>`, for example:

```
matthew@seymour:~$ ln -s myfile.txt mylink
```

That creates the symlink `mylink` that points to `myfile.txt`. You don’t see it here, but the file I created is 341 bytes. This is important later. Remove the `-s` to create a hard link. You can verify that your link has been created by running `ls -l`. Your symlink should look something like this:

```
lwrwxrwxrwx 1 matthew matthew 5 Feb 19 12:39 mylink -> myfile.txt
```

Note how the file properties start with `l` (lowercase L) for link and how `ls -l` also prints where the link is going. Symlinks are always very small in size; the previous link is 5 bytes. If you created a hard link, it should look like this:

```
-rw-rw-r   2 matthew matthew   341 Feb 19 12:39 mylink
```

This time the file has normal attributes, but the second number is 2 rather than 1. That number is how many hard links point to this file, which is why it is 2 now. The file size is also the same as that of the previous filename because it is the file, as opposed to just being a pointer.

Symlinks are used extensively in Linux. Programs that have been superseded, such as `sh`, now point to their replacements (in this case `bash`), and library versioning is accomplished through symlinks. For example, applications that link against `zlib` load `/usr/lib/libz.so`. Internally, however, that is just a symlink that points to the actual `zlib` library: `/usr/lib/libz.so.1.2.1.2`. This enables multiple versions of libraries to be installed without application developers needing to worry about these specific details.
Finding Files from an Index with `locate`

When you use the `find` command, it searches recursively through each directory each time you request a file. This is slow, as you can imagine. Fortunately, Ubuntu ships with a `cron` job that creates an index of all the files on your system every night. Searching this index is extremely fast, which means that if the file you are looking for has been around since the last index, this is the preferable way of searching.

To look for a file in your index, use the command `locate` followed by the names of the files you want to find, like this:

```
matthew@seymour:-$ locate myfile.txt
```

On a relatively modern computer (1.5GHz or higher), `locate` should be able to return all the matching files in under a second. The trade-off for this speed is lack of flexibility. You can search for matching filenames, but, unlike `find`, you cannot search for sizes, owners, access permissions, or other attributes. The one thing you can change is case sensitivity; use the `-i` parameter to do a search that is not case sensitive.

Although Ubuntu rebuilds the filename index nightly, you can force a rebuild whenever you want by running the command `updatedb` with `sudo`. This usually takes a few minutes, but when it’s done the new database is immediately available.

Listing Files in the Current Directory with `ls`

The `ls` command, like `ln`, is one of those you expect to be very straightforward. It lists files, but how many options can it possibly have? In true Linux style, the answer is many, although again you need only know a few to wield great power!

The basic usage is simply `ls`, which lists the files and directories in the current location. You can filter that using normal wildcards, so all these are valid:

```
matthew@seymour:-$ ls *
matthew@seymour:-$ ls *.txt
matthew@seymour:-$ ls my*ls *.txt *.xml
```

Any directories that match these filters are recursed into one level. That is, if you run `ls my*` and you have the files `myfile1.txt` and `myfile2.txt` and a directory `mystuff`, the matching files are printed first. Then `ls` prints the contents of the `mystuff` directory.

The most popular parameters for customizing the output of `ls` are

- `a`—Includes hidden files.
- `h`—Uses human-readable sizes.
- `l`—A lowercase L, it enables long listing.
- `r`—Reverse order.
- `R`—Recursively lists directories.
- `s`—Shows sizes.
- `sort`—Sorts the listing.
All files that start with a period are hidden in Linux, so that includes the .gnome directory in your home directory, as well as .bash_history and the . and .. implicit directories that signify the current directory and the parent. By default, ls does not show these files, but if you run ls -a, they are shown. You can also use ls -A to show all the hidden files except . and ...

The -h parameter needs to be combined with the -s parameter, like this:

```
matthew@seymour:~$ ls -sh *.txt
```

That outputs the size of each matching file in a human-readable format, such as 108KB or 4.5MB.

Using the -l parameter enables much more information about your files. Instead of just providing the names of the files, you get output like this:

```
drwxrwxr-x 24 matthew matthew 4096 Dec 24 21:33 arch
-rw-r--r--  1 matthew matthew 18691 Dec 24 21:34 COPYING
-rw-r--r--  1 matthew matthew 88167 Dec 24 21:35 CREDITS
drwxrwxr-x  2 matthew matthew 4096 Dec 24 21:35 crypto
```

That shows four matches and prints a lot of information about each of them. The first row shows the arch directory; you can tell it is a directory because its file attributes starts with a d. The rwxrwxr-x following that shows the access permissions, and this has special meanings because it is a directory. Read access for a directory allows users to see the directory contents, write access allows you to create files and subdirectories, and execute access allows you to cd into the directory. If a user has execute access but not read access, the user will be able to cd into the directory but not list files.

Moving on, the next number on the line is 24, which also has a special meaning for directories: It is the number of subdirectories, including . and .. After that is matthew matthew, which is the name of the user owner and the group owner for the directory. Next is the size and modification time, and finally the directory name itself.

The next line shows the file COPYING, and most of the numbers have the same meaning, with the exception of the 1 immediately after the access permissions. For directories, this is the number of subdirectories, but for files this is the number of hard links to this file. A 1 in this column means this is the only filename pointing to this inode, so if you delete it, it is gone.

Ubuntu comes configured with a shortcut command for ls -l: ll.

The --sort parameter allows you to reorder the output from the default alphabetical sorting. You can sort by various things, although the most popular are extension (alphabetically), size (largest first), and time (newest first). To flip the sorting (making size sort by smallest first), use the -r parameter also. So, this command lists all .ogg files, sorted smallest to largest:

```
matthew@seymour:~$ ls --sort size -r *.ogg
```

Finally, the -R parameter recurses through subdirectories. For example, typing `ls /etc` lists all the files and subdirectories in `/etc`, but `ls -R /etc` lists all the files in and subdirectories in `/etc`, all the files and subdirectories in `/etc/acpi`, all the files and subdirectories in `/etc/acpi/actions`, and so on until every subdirectory has been listed.

**Reading Manual Pages with man**

Time for a much-needed mental break: The `man` command is easy to use. Most people use only the topic argument, like this: `man gcc`. However, two other commands work closely with `man` that are very useful—`whatis` and `apropos`.

The `whatis` command returns a one-line description of another command, which is the same text you get at the top of that command’s `man` page. For example:

```
matthew@seymour:~$ whatis ls
ls    (1) - list directory contents
```

The output there explains what `ls` does but also provides the `man` page section number for the command so you can query it further.

On the other hand, the `apropos` command takes a search string as its parameter and returns all `man` pages that match the search. For example, `apropos mixer` returns this list:

```
alsamixer (1) - soundcard mixer for ALSA soundcard driver
mixer (1) - command-line mixer for ALSA soundcard driver
aumix (1) - adjust audio mixer
```

So, use `apropos` to help you find commands and use `whatis` to tell you what a command does.

One neat trick is that many of the tips and tricks we learned for `less` also work when viewing `man` pages. For example, using `/` and `?` to search. This is one of the beautiful things about UNIX systems, gaining knowledge in one area often benefits you in other areas.

**Making Directories with mkdir**

Making directories is as easy as it sounds, although there is one parameter you should be aware of: `-p`. If you are in `/home/matthew` and you want to create the directory `/home/matthew/audio/sound`, you will get an error like this:

```
mkdir: cannot create directory `audio/sound': No such file or directory
```

At first glance this seems wrong; `mkdir` cannot create the directory because it does not exist. What it actually means is that it cannot create the directory `sound` because the directory `audio` does not exist. This is where the `-p` parameter comes in: If you try to make a directory within another directory that does not exist, like the previous, `-p` creates the parent directories, too. So:

```
matthew@seymour:~$ mkdir -p audio/sound
```
That first creates the audio directory and then creates the sound directory inside it.

**Moving Files with mv**

This command is one of the easiest around. There are two helpful parameters to `mv`: `-f`, which overwrites files without asking, and `-u`, which moves the source file only if it is newer than the destination file. That is it!

**Listing Processes with ps**

This is the third and last “command that should be simple, but isn’t” that is discussed here. The `ps` command lists processes and gives you an extraordinary amount of control over its operation.

The first thing to know is that `ps` is typically used with what are known as BSD-style parameters. Back in the section “Finding Files by Searching with `find`,” we discussed UNIX-style, GNU-style, and X-style parameters (`-c`, `--dosomething`, and `-dosomething`, respectively), but BSD-style parameters are different because they use single letters without a dash.

So, the default use of `ps` lists all processes that you are running that are attached to the terminal. However, you can ask it to list all your processes attached to any terminal (or indeed no terminal) by adding the `x` parameter: `ps x`. You can ask it to list all processes for all users with the `a` parameter or combine that with `x` to list all processes for all users, attached to a terminal or otherwise: `ps ax`.

However, both of these are timid compared with the almighty `u` option, which enables user-oriented output. In practice, that makes a huge difference because you get important fields like the username of the owner, how much CPU time and RAM are being used, when the process was started, and more. This outputs a lot of information, so you might want to try adding the `f` parameter, which creates a process forest by using ASCII art to connect parent commands with their children. You can combine all the options so far with this command: `ps faux` (yes, with a little imagination you spell words with the parameters!).

You can control the order in which the data is returned by using the `-sort` parameter. This takes either `a +` or `a -` (although the `+` is default) followed by the field you want to sort by: `command`, `%cpu`, `pid`, and `user` are all popular options. If you use the minus sign, the results are reversed. This next command lists all processes, ordered by CPU usage descending:

```
matthew@seymour:$ ps aux --sort=-%cpu
```

There are many other parameters for `ps`, including a huge amount of options for compatibility with other UNIXes. If you have the time to read the man page, you should give it a try.
Deleting Files and Directories with `rm`

The `rm` command has only one parameter of interest: `--preserve-root`. By now, you should know that issuing `rm -rf /` with `sudo` will destroy your Linux installation because `-r` means recursive and `-f` means force (do not prompt for confirmation before deleting). It is possible for a clumsy person to issue this command by accident—not by typing the command on purpose, but by putting a space in the wrong place. For example:

```
matthew@seymour:~$ rm -rf /home/matthew
```

That command deletes the home directory of the user `matthew`. This is not an uncommon command; after you have removed a user and backed up the user’s data, you will probably want to issue something similar. However, if you add an accidental space between the `/` and the `h` in “home”, you get this:

```
matthew@seymour:~$ rm -rf / home/matthew
```

This time the command means “delete everything recursively from `/` and then delete `home/matthew`”—quite a different result! You can stop this from happening by using the `--preserve-root` parameter, which stops you from catastrophe with this message:

```
rm: it is dangerous to operate recursively on '/'
```

```
rm: use --no-preserve-root to override this failsafe.
```

However, no one wants to keep typing `--preserv-root` each time they run `rm`, so you could add this line to the `.bashrc` file in your home directory:

```
alias rm='rm --preserve-root'
```

That alias automatically adds `--preserve-root` to all calls to `rm` in future Bash sessions. Ubuntu (and Debian, and perhaps other distributions now) have done this by default, not by adding an alias in `bashrc`, but by making `--preserve-root` the default for the command.

Printing the Last Lines of a File with `tail`

If you want to watch a log file as it is written to, or want to monitor a user’s actions as they are occurring, you need to be able to track log files as they change. In these situations you need the `tail` command, which prints the last few lines of a file and updates as new lines are added. This command tells `tail` to print the last few lines of `/var/log/httpd/access_log`, the Apache hit log:

```
matthew@seymour:~$ tail /var/log/httpd/access_log
```

To get `tail` to remain running and update as the file changes, add the `-f` parameter (follow):

```
matthew@seymour:~$ tail -f /var/log/httpd/access_log
```

You can tie the lifespan of a `tail` follow to the existence of a process by specifying the `--pid` parameter. When you do this, `tail` continues to follow the file you asked for until it sees that the process identified by PID is no longer running, at which point it stops tailing.

If you specify multiple files on the command line, `tail` follows both, printing file headers whenever the input source changes. Press Ctrl+C to terminate `tail` when in follow mode.
**Printing Resource Usage with top**

The `top` command is unusual in this list because the few parameters it takes are rarely, if ever, used. Instead, it has a number of commands you can use while it is running to customize the information it shows you. To get the most from these instructions, open two terminal windows. In the first, run the program `yes` and leave it running; in the second run `top`.

The default sort order in `top` shows the most CPU-intensive tasks first. The first command there should be the `yes` process you just launched from the other terminal, but there should be many others also. First, we want to filter out all the other users and focus on the user running `yes`. To do this, press u and enter the username you used when you ran `yes`. When you press Enter, `top` filters out processes not being run by that user.

The next step is to kill the process ID of the `yes` command, so you need to understand what each of the important fields means:

- **PID**—The process ID
- **User**—The owner of the process
- **PR**—Priority
- **NI**—Niceness
- **Virt**—Virtual image size in kilobytes
- **Res**—Resident size in kilobytes
- **Shr**—Shared memory size in kilobytes
- **S**—Status
- **%CPU**—CPU usage
- **%Mem**—Memory usage
- **Time+**—CPU time
- **Command**—The command being run

Several of them are unimportant unless you have a specific problem. The ones we are interested in are PID, User, Niceness, %CPU, %MEM, Time+, and Command. The Niceness of a process is how much time the CPU allocates to it compared to everything else on the system: 19 is the lowest, and –19 is the highest.

With the columns explained, you should be able to find the process ID of the errant `yes` command launched earlier; it is usually the first number below PID. Now type k, enter that process ID, and press Enter. You are prompted for a signal number (the manner in which you want the process killed), with 15 provided as the default. Signal 15 (also known as `SIGTERM`, for “terminate”) is a polite way of asking a process to shut down, and all processes that are not wildly out of control should respond to it. Give `top` a few seconds to update itself, and hopefully the `yes` command should be gone. If not, you need to be
more forceful: type k again, enter the PID, and press Enter. When prompted for a signal to
send, enter 9 and press Enter to send SIGKILL, or “terminate whether you like it or not.”

You can choose the fields to display by pressing f. A new screen appears that lists all possi-
ble fields, along with the letter you need to press to toggle their visibility. Selected fields
are marked with an asterisk and have their letter, for example:

* A: PID        = Process Id

If you press the a key, the screen changes to this:

a: PID        = Process Id

When you have made your selections, press Enter to return to the normal top view with
your normal column selection.

You can also press F to select the field you want to use for sorting. This works in the same
way as the field selection screen, except that you can select only one field at a time. Again,
press Enter to get back to top after you have made your selection, and it will be updated
with the new sorting.

If you press B, text bolding is enabled. By default, this bolds some of the header bar as
well as any programs that are currently running (as opposed to sleeping), but if you press
x you can also enable bolding of the sorted column. You can use y to toggle bolding of
running processes.

The last command to try is r, which allows you to renice—or adjust the nice value—of a
process. You need to enter the PID of the process, press Enter, and enter a new nice value.
Keep in mind that 19 is the lowest and –20 is the highest; anything less than 0 is consid-
ered “high” and should be used sparingly.

**Printing the Location of a Command with which**

The purpose of which is to tell you the exact command that would be executed if you
typed it. For example, which mkdir returns /bin/mkdir, telling you that running the
command mkdir runs /bin/mkdir.

**Combining Commands**

So far, we have been using commands only individually, and for the large part that is
what you will be doing in practice. However, some of the real power of these commands
lies in the capability to join them together to get exactly what you want. There are some
extra little commands that we have not looked at that are often used as glue because they
do one very simple thing that enables a more complex process to work.
All the commands we have looked at have printed their information to the screen, but this is often flexible. There are two ways to control where output should go: piping and output redirection. A pipe is a connector between one command’s output and another’s input. Instead of sending its output to your terminal, using a pipe sends that output directly to another command as input. Output redirection works in a similar way to pipes but is usually used for files. We will look at pipes first and then output redirection.

Two of the commands we have looked at so far are `ps` and `grep`: the process lister and the string matcher. We can combine the two to find out which users are playing Nethack right now:

```
matthew@seymour:~$ ps aux | grep nethack
```

That creates a list of all the processes running right now and sends that list to the `grep` command, which filters out all lines that do not contain the word `nethack`. Ubuntu allows you to pipe as many commands as you can sanely string together. For example, we could add in the `wc` command, which counts the numbers of lines, words, and characters in its input, to count precisely how many times Nethack is being run:

```
matthew@seymour:~$ ps aux | grep nethack | wc -l
```

The `-l` parameter (lowercase L) to `wc` prints only the line count.

Using pipes in this way is often preferable to using the `-exec` parameter to find, simply because many people consider `find` to be a black art and so anything that uses it less frequently is better! This is where the `xargs` command comes in: It converts output from one command into arguments for another.

For a good example, consider this mammoth `find` command from earlier:

```
matthew@seymour:~$ find / -name "*.txt" -size +10k -user matthew -not -perm +o=r -exec chmod o+r {} \;
```

That searches every directory from `/` onward for files matching `*.txt` that are greater than 10KB, are owned by user `matthew`, and do not have read permission for others. Then it executes `chmod` on each of the files. It is a complex command, and people who are not familiar with the workings of `find` might have problems understanding it. So, what we can do is break it up into two—a call to `find` and a call to `xargs`. The most conversion would look like this:

```
matthew@seymour:~$ find / -name "*.txt" -size +10k -user matthew -not -perm +o=r | xargs chmod o+r
```

That has eliminated the confusing `{}` `\;` from the end of the command, but it does the same thing, and faster, too. The speed difference between the two is because using `-exec` with `find` causes it to execute `chmod` once for each file. However, `chmod` accepts many files at a time and, because we are using the same parameter each time, we should take advantage of that. The second command, using `xargs`, is called once with all the output from `find`, and so saves many command calls. The `xargs` command automatically places the input at the end of the line, so the previous command might look something like this:

```
matthew@seymour:~$ xargs chmod o+r file1.txt file2.txt file3.txt
```
Not every command accepts multiple files, though, and if you specify the `-l` parameter, `xargs` executes its command once for each line in its input. If you want to check what it is doing, use the `-p` parameter to have `xargs` prompt you before executing each command.

For even more control, the `-i` parameter allows you to specify exactly where the matching lines should be placed in your command. This is important if you need the lines to appear before the end of the command or need it to appear more than once. Either way, using the `-i` parameter also enables the `-l` parameter so each line is sent to the command individually. This next command finds all files in `/home/matthew` that are larger than 10,000KB in size (10MB) and copies them to `/home/matthew/archive`:

```
matthew@seymour:~$ find /home/matthew -size +10000k | xargs -i cp {} ./home/matthew/archive
```

Using find with `xargs` is a unique case. All too often, people use pipes when parameters would do the job just as well. For example, these two commands are identical:

```
matthew@seymour:~$ ps aux --sort=-%cpu | grep -v 'whoami'
matthew@seymour:~$ ps -N ux --sort=-%cpu
```

The former prints all users and processes and then pipes that to `grep`, which in turn filters out all lines that contain the output from the program `whoami` (our username). So, line one prints all processes being run by other users, sorted by CPU use. Line two does not specify the `a` parameter to `ps`, which makes it list only our parameters. It then uses the `-N` parameter to flip that, which means it is everyone but us, without the need for `grep`.

The reason people use the former is often just simplicity: Many people know only a handful of parameters to each command, so they can string together two commands simply rather than write one command properly. Unless the command is to be run regularly, this is not a problem. Indeed, the first line would be better because it does not drive people to the manual to find out what `ps -N` does!

## Multiple Terminals

Many Linux veterans have enjoyed and use the `screen` command. Screen was designed to allow you to use one terminal to control several terminal sessions easily. While `screen` has been a welcome and useful tool, a better one has appeared called Byobu which is an enhanced version of Screen. The name Byobu is a Japanese term for decorative, multipanel vertically folding screens that are often used as room dividers.

Picture this scene: You connect to a server via SSH and are working at the remote shell. You need to open another shell window so you can have the two running side by side; perhaps you want the output from `top` in one window while typing in another. What do you do? Most people would open another SSH connection, but that is both wasteful and unnecessary. Like Screen, Byobu is a terminal multiplexer, which is a fancy term for a program that lets you run multiple terminals inside one terminal.
The best way to learn Byobu is to try it yourself, so open a console, type `byobu`, and then press Enter. Your display will blank momentarily and then be replaced with a new console with new information in a panel at the bottom. Now, let’s do something with that terminal. Run `top` and leave it running for the time being. Press F2. Your prompt will clear again, leaving you able to type. Run the `uptime` command.

Pop quiz: What happened to the old terminal running `top`? It is still running, of course. You can type F3 to return to it. Type F4 to go back to your `uptime` terminal. While you are viewing other terminals, the commands in the other terminals carry on running as normal so you can multitask. Here are some of the basic commands in Byobu:

- F2—Create a new window
- F3—Go to the previous window
- F4—Go to the next window
- F9—Open Byobu menu for help and configuration

To close a terminal within Byobu, simply log out of it normally using `exit` or `ctrl-d`. When you exit the last terminal session that is open in Byobu, the program closes as well and drops you to the regular terminal session you used to start Byobu.

However, there are two alternatives to quitting a Byobu session: locking and disconnecting. The first, activated with F12, locks access to your screen data until you enter your system password.

The second is the most powerful feature of Screen that also works beautifully in Byobu: you can exit it and do other things for a while and then reconnect later—and both Screen and Byobu will pick up where you left off. For example, you could be typing at your desk, detach from a session and go home, reconnect, and carry on as if nothing had changed. What’s more, all the programs you ran from Screen or Byobu carry on running even while Screen or Byobu is disconnected. It even automatically disconnects for you if someone closes your terminal window while it is in a locked state (with `Ctrl+a+x`).

To disconnect, press F6. You are returned to the prompt from which you launched Screen or Byobu and can carry on working, close the terminal you had opened, or even log out completely. When you want to reconnect, run the command `screen -r` or `byobu -r`. You can, in the meantime, just run `screen` or `byobu` and start a new session without resuming the previous one, but that is not wise if you value your sanity! You can disconnect and reconnect the same session as many times you want, which potentially means you need never lose your session again.

Although this has been a mere taste of what Byobu/Screen can do, hopefully you can see how useful it can be. Check the man pages for each to learn more.
Reference

- http://www.gnu.org/—The website of the GNU project, it contains manuals and downloads for lots of command-line software.
- http://www.linuxcommand.org/—Describes itself as “your one-stop command line shop!” It contains a wealth of useful information about the console.
- Understanding the way UNIX works at the nuts and bolts level can be both challenging and rewarding, and there are several good books that will help guide you on your way. Perhaps the best is *The Art of Unix Programming* by Eric Raymond (Addison-Wesley, ISBN: 0-13-142901-9), which focuses on the philosophy behind UNIX and manages to mix in much about the command line.
- O’Reilly’s *Unix CD Bookshelf* (ISBN: 0-596-00392-7) contains seven highly respected books in one, although it retails for more than $120 as a result! However, it is incomparable in its depth and breadth of coverage.
This page intentionally left blank
A kernel is a complex piece of software that manages the processes and process interactions that take place within an operating system. As a user, you rarely, if ever, interact directly with it. Instead, you work with the applications that the kernel manages.

The Linux kernel is Linux. It is the result of years of cooperative (and sometimes contentious) work by numerous people around the world. There is only one common kernel source tree, but each major Linux distribution massages and patches its version slightly to add features, performance, or options. Each Linux distribution, including Ubuntu, comes with its own precompiled kernel as well as the kernel source code, providing you with absolute authority over the Linux operating system. In this chapter, we will examine the kernel and learn what it does for us and for the operating system.

In this chapter, you also learn how to obtain the kernel sources, as well as how and when to patch the kernel. The chapter leads you through an expert’s tour of the kernel architecture and teaches you essential steps in kernel configuration, how to build and install modules, and how to compile drivers in Ubuntu. This chapter also teaches you important aspects of working with GRUB2, the default Ubuntu boot loader. Finally, the chapter’s troubleshooting information will help you understand what to do when something goes wrong with your Linux kernel installation or compilation process. As disconcerting as these problems can seem, this chapter shows you some easy fixes for many kernel problems.

Almost all users find that a precompiled Ubuntu kernel suits their needs (and there are several to choose from). At
some point, you might need to recompile the kernel to support a specific piece of hardware or add a new feature to the operating system, although the Ubuntu kernel team works very hard to backport or enable any feature possible (as a module) so it is highly unlikely you will ever have a need to do this. They are also approachable and will gladly discuss specific needs and features. Sometimes features are not enabled simply because no one has ever asked for or needed them. Occasionally there are things not enabled because of a conflict with another feature. The Ubuntu Kernel Team can help you discover what is going on in those cases (but don’t abuse their kindness and availability, they already work quite hard and for long hours).

Really, the main reason today for people compiling their own kernel is because they want to learn to be a kernel developer. If you have heard horror stories about the difficulties of recompiling the Linux kernel, you can relax; this chapter gives you all the information you need to understand how to painlessly work through the process if you are interested in learning a new skill. This is a complex and detail-oriented task, but it is within the grasp of most technical users, even if it is completely unnecessary.

**WARNING**

Building and using a custom kernel will make it very difficult to get support for your system. Although it is a learning experience to compile your own kernel, you will not be allowed to file bugs in Ubuntu on the custom-built kernel (if you do, they will be rejected without further explanation) and if you have a commercial support contract with Ubuntu/Canonical, this will void the contract.

**The Linux Kernel**

The Linux kernel is the management part of the operating system that many people call “Linux.” Although many think of the entire distribution as Linux, the only piece that can correctly be called Linux is the kernel. Ubuntu, like many Linux distributions, includes a kernel packaged with add-on software that interacts with the kernel so that the user can interface with the system in a meaningful manner.

The system utilities and user programs enable computers to become valuable tools to a user.

**THE FIRST LINUX KERNEL**

In 1991, Linus Torvalds released version .99 of the Linux kernel as the result of his desire for a powerful, UNIX-like operating system for his Intel 80386 personal computer. Linus wrote the initial code necessary to create what is now known as the Linux kernel and combined it with Richard Stallman’s GNU tools. Indeed, because many of the Linux basic system tools come from the GNU Project, many people refer to the operating system as GNU/Linux. Since then, Linux has benefited from thousands of contributors adding their talents and time to the Linux project. Linus still maintains the kernel, deciding on what will and will not make it into the kernel as official releases, known to many as the “vanilla” or “Linus” Linux kernel.
The Linux Source Tree

The source code for the Linux kernel is kept in a group of directories called the kernel source tree. The structure of the kernel source tree is important because the process of compiling (building) the kernel is automated; it is controlled by scripts interpreted by the make application. These scripts, known as makefiles, expect to find the pieces of the kernel code in specific places or they will not work. You will learn how to use make to compile a kernel later in this chapter.

It is not necessary for the Linux kernel source code to be installed on your system for the system to run or for you to accomplish typical tasks such as email, web browsing, or word processing. It is necessary that the kernel sources be installed, however, if you want to compile a new kernel. In the next section, we will show you how to install the kernel source files and how to set up the special symbolic link required. That link is /usr/src/linux-2.6, and it is how we will refer to the directory of the kernel source tree as we examine the contents of the kernel source tree.

The /usr/src/linux-2.6 directory contains the .config and the Makefile files among others. The .config file is the configuration of your Linux kernel as it was compiled. There is no .config file by default; you must select one from the /configs subdirectory. There, you will find configuration files for each flavor of the kernel Ubuntu provides; simply copy the one appropriate for your system to the default directory and rename it .config.

We have already discussed the contents of the /configs subdirectory, so let us examine the other directories found under /usr/src/linux-2.6. The most useful for us is the Documentation directory. In it and its subdirectories, you will find almost all the documentation concerning every part of the kernel. The file 00-INDEX (each Documentation subdirectory also contains a 00-INDEX file as well) contains a list of the files in the main directory and a brief explanation of what they are. Many files are written solely for kernel programmers and application writers, but a few are useful to the intermediate or advanced Linux user when attempting to learn about kernel and device driver issues. Some of the more interesting and useful documents are:

- devices.txt—A list of all possible Linux devices that are represented in the /dev directory, giving major and minor numbers and a short description. If you have ever gotten an error message that mentions char-major-xxx, this file is where that list is kept.

- ide.txt—If your system uses IDE hard drives, this file discusses how the kernel interacts with them and lists the various kernel commands that can be used to solve IDE-related hardware problems, manually set data transfer modes, and otherwise manually manage your IDE drives. Most of this management is automatic, but if you want to understand how the kernel interacts with IDE devices, this file explains it.

- initrd.txt—This file provides much more in-depth knowledge of initial ramdisks, giving details on the loopback file system used to create and mount them and explaining how the kernel interacts with them.

- kernel-parameters.txt—This file is a list of most of the arguments that you can pass at boot time to configure kernel or hardware settings, but it does not appear too
useful at first glance because it is just a list. However, knowing that a parameter exists and might relate to something you are looking for can assist you in tracking down more information because now you have terms to enter into an Internet search engine such as www.google.com/linux.

- **sysrq.txt**—If you have ever wondered what that key on your keyboard marked “SysRq” was used for, this file has the answer. Briefly, it is a key combination hard-wired into the kernel that can help you recover from a system lockup. Ubuntu disables this function by default for security reasons. You can re-enable it by entering the command `# echo "1" > /proc/sys/kernel/sysrq` and disable it by echoing a value of 0 instead of 1.

In the other directories found in Documentation, you will find similar text files that deal with the kernel modules for CD-ROM drivers, file system drivers, gameport and joystick drivers, video drivers (not graphics card drivers—those belong to X11R6 and not to the kernel), network drivers, and all the other drivers and systems found in the Linux operating system. Again, these documents are usually written for programmers, but they can provide useful information to the intermediate and advanced Linux user as well.

The directory named **scripts** contains many of the scripts that `make` uses. It really does not contain anything of interest to anyone who is not a programmer or a kernel developer (also known as a kernel hacker).

After a kernel is built, all the compiled files will wind up in the arch directory and its subdirectories. Although you can manually move them to their final location, we will show you later in this chapter how the `make` scripts will do it for you. In the early days of Linux, this post-compilation file relocation was all done by hand; you should be grateful for `make`.

**NOTE**

The `make` utility is a very complex program. Complete documentation on the structure of `make` files, as well as the arguments that it can accept, can be found at www.gnu.org/software/make/manual/make.html.

The remainders of the directories in `/usr/src/linux-2.6` contain the source code for the kernel and the kernel drivers. When you install the kernel sources, these files are placed there automatically. When you patch kernel sources, these files are altered automatically. When you compile the kernel, these files are accessed automatically. Although you never need to touch the source code files, they can be useful. The kernel source files are nothing more than text files with special formatting, which means that we can look at them and read the programmers’ comments. Sometimes, a programmer will write an application, but cannot (or often will not) write the documentation. The comments the programmer puts in the source code are often the only documentation that exists for the code.

Small testing programs are even “hidden” in the comments of some of the code, along with comments and references to other information. Because the source code is written in a language that can be read as easily—almost—as English, a nonprogrammer might be able
to get an idea of what the application or driver is actually doing (see Chapter 30, “C/C++ Programming Tools for Ubuntu”). This information might be of use to an intermediate to advanced Linux user when the user is confronted by kernel- and driver-related problems.

**NOTE**

The interaction and control of hardware is handled by a small piece of the kernel called a device driver. The driver tells the computer how to interact with a modem, a SCSI card, a keyboard, a mouse, and so on in response to a user prompt. Without the device driver, the kernel does not know how to interact with the associated device.

**Types of Kernels**

In the early days of Linux, kernels were a single block of code containing all the instructions for the processor, the motherboard, and the other hardware. If you changed hardware, you were required to recompile the kernel code to include what you needed and discard what you did not. Including extra, unneeded code carried a penalty because the kernel became larger and occupied more memory. On older systems that had only 4MB–8MB of memory, wasting precious memory for unnecessary code was considered unacceptable. Kernel compiling was something of a “black art” as early Linux users attempted to wring the most performance from their computers. These kernels compiled as a single block of code are called *monolithic kernels*.

As the kernel code grew larger and the number of devices that could be added to a computer increased, the requirement to recompile became onerous. A new method of building the kernel was developed to make the task of compiling easier. The part of the kernel’s source code that composed the code for the device drivers could be optionally compiled as a module that could be loaded and unloaded into the kernel as required. This is known as the *modular* approach to building the kernel. Now, all the kernel code could be compiled at once—with most of the code compiled into these modules. Only the required modules would be loaded; the kernel could be kept smaller, and adding hardware was much simpler.

The typical Ubuntu kernel has some drivers compiled as part of the kernel itself (called *inline* drivers) and others compiled as modules. Only device drivers compiled in-line are available to the kernel during the boot process; modular drivers are available only after the system has been booted.

**NOTE**

As a common example, drivers for SCSI disk drives must be available to the kernel if you intend to boot from SCSI disks. If the kernel is not compiled with those drivers in-line, the system will not boot because it will not be able to access the disks.

A way around this problem for modular kernels is to use an initial Ram disk (*initrd*) discussed later in “Creating an Initial RAM Disk Image.” The *initrd* loads a small kernel and the appropriate device driver, which then can access the device to load the actual kernel you want to run.
Some code can be only one or the other (for technical reasons unimportant to the average user), but most code can be compiled either as modular or in-line. Depending on the application, some system administrators prefer one way over the other, but with fast modern processors and abundant system memory, the performance differences are of little concern to all but the most ardent Linux hackers.

When compiling a kernel, the step in which you make the selection of modular or in-line is part of the `make config` step that we will detail later in this chapter. Unless you have a specific reason to do otherwise, we suggest that you select the modular option when given a choice. The process of managing modules is addressed in the next section because you will be managing them more frequently than you will be compiling a kernel.

### Managing Modules

When using a modular kernel, special tools are required to manage the modules. Modules must be loaded and unloaded, and it would be nice if that were done as automatically as possible. We also need to be able to pass necessary parameters to modules when we load them—things such as memory addresses and interrupts. (That information varies from module to module, so you will need to look at the documentation for your modules to determine what, if any, information needs to be passed to it.) In this section, we will cover the tools provided to manage modules and then look at a few examples of using them.

Linux provides the following module management tools for our use. All these commands (and `modprobe.conf`) have `man` pages:

- **lsmod**—This command lists the loaded modules. It is useful to pipe this through the `less` command because the listing is usually more than one page long.

- **insmod**—This command loads the specified module into the running kernel. If a module name is given without a full path, the default location for the running kernel, `/lib/modules/*/`, will be searched. Several options are offered for this command—the most useful is `-f`, which forces the module to be loaded.

- **rmmod**—This command unloads (removes) the specified module from the running kernel. More than one module at a time can be specified.

- **modprobe**—A more sophisticated version of `insmod` and `rmmod`, it uses the dependency file created by `depmod` and automatically handles loading, or with the `-r` option, removing modules. There is no force option, however. A useful option to `modprobe` is `-t`, which causes `modprobe` to cycle through a set of drivers until it finds one that matches your system. If you were unsure of what module would work for your network card, you would use this command:

  ```bash
  matthew@seymour:~$ sudo modprobe -t net
  ```

  The term `net` is used because that is the name of the directory
  (`/lib/modules/*/kernel/net`) where all the network drivers are kept. It will try each one in turn until it loads one successfully.

- **modinfo**—This will query a module's object file and provide a list of the module name, author, license, and any other information that is there. It often is not very useful.
Managing Modules

- **depmod**—This program creates a dependency file for kernel modules. Some modules need to have other modules loaded first; that is, they “depend” on the other modules. (A lot of the kernel code is like this because it eliminates redundancy in the code base.) During the boot process, one of the startup files contains the command `depmod -a` and it is run every time you boot to re-create the file `/lib/modules/*/modules.dep`. If you make changes to the file `/etc/modprobe.conf`, run `depmod -a` manually. The `depmod` command, its list of dependencies, and the `/etc/modprobe.conf` file enable kernel modules to be automatically loaded as needed.

- **/etc/modprobe.conf**—This is not a command, but a file that controls how `modprobe` and `depmod` behave; it contains kernel module variables. Although the command syntax can be quite complex, most actual needs are very simple. The most common use is to alias a module and then passes it some parameters. For example, in the following code, we alias a device name (from `devices.txt`) to a more descriptive word and then pass some information to an associated module. The `i2c-dev` device is used to read the CPU temperature and fan speed on our system. These lines for `/etc/modprobe.conf` were suggested for our use by the program’s documentation. We added them with a text editor.

```
alias char-major-89 i2c-dev
options eeprom ignore=2,0x50,2,0x51,2,0x52
```

A partial listing of `lsmod` is shown here, piped through the `less` command, allowing us to view it a page at a time:

```
matthew@seymour:~$ sudo lsmod | less
Module             Size  Used by
parport_pc        19392  1
Module             Size  Used by
parport_pc        19392  1
lp                 8236  0
parport           29640  2 parport_pc,lp
autofs4           10624  0
sunrpc           101064  1
```

The list is actually much longer, but here we see that the input module is being used by the `joydev` (joystick device) module, but the joystick module is not being used. This computer has a joystick port that was auto detected, but no joystick is connected. A scanner module is also loaded, but because the USB scanner is unplugged, the module is not being used. You would use the `lsmod` command to determine whether a module was loaded and what other modules were using it. If you examine the full list, you would see modules for all the devices attached to your computer.

To remove a module, `joydev` in this example, use:

```
matthew@seymour:~$ sudo rmmod joydev
```
or

```
matthew@seymour:~$ sudo modprobe -r joydev
```
A look at the output of `lsmod` would now show that it is no longer loaded. If we removed input as well, we could then use `modprobe` to load both input and joydev (one depends on the other, remember) with a simple

```
matthew@seymour:~$ sudo modprobe joydev
```

If Ubuntu balks at loading a module (because it had been compiled using a different kernel version from what we are currently running; for example, the NVIDIA graphics card module), we could force it to load like this:

```
matthew@seymour:~$ sudo insmod -f nvidia
```

We would ignore the complaints (error messages) in this case if the kernel generated any.

## When to Recompile

Ubuntu systems use a modified version of the plain vanilla Linux kernel (a modified version is referred to as a *patched* kernel) with additional drivers and other special features compiled into it.

Ubuntu has quite an intensive testing period for all distribution kernels and regularly distributes updated versions. The supplied Ubuntu kernel is compiled with as many modules as possible to provide as much flexibility as possible. A running kernel can be further tuned with the `sysctl` program, which enables direct access to a running kernel and permits some kernel parameters to be changed. As a result of this extensive testing, configurability, and modularity, the precompiled Ubuntu kernel does everything most users need it to do. Most users only need to recompile the kernel to:

- Accommodate an esoteric piece of new hardware.
- Conduct a system update when Ubuntu has not yet provided precompiled kernels.
- Experiment with the system capabilities.

Ubuntu supplies precompiled versions of the kernel for 32 and 64 bit processors. For each architecture, they compile a generic kernel that will work well for most uses, a server kernel that is optimized for server use, a preempt kernel designed for use in low latency servers, and an `rt` kernel for times when instant response is more important than balanced use (such as in professional audio/visual recording and editing). There is also a special kernel available for use in virtual machines called virtual. These are all available from the Ubuntu software repositories.

Also available are a series of packages called `linux-backports-modules-`, each with a specific set of kernel modules backported from newer mainline kernels into current version Ubuntu kernels. If you need an updated driver for a piece of hardware, you should look at the backported modules first.

## Kernel Versions

The Linux kernel is in a constant state of development. As new features are added, bugs are fixed, and new technology is incorporated into the code base, it becomes necessary to provide stable releases of the kernel for use in a production environment. It is also impor-
tant to have separate releases that contain the newest code for developers to test. To keep track of the kernels, version numbers are assigned to them. Programmers enjoy using sequential version numbers that have abstract meaning. Is version 8 twice as advanced as version 4 of the same application? Is version 1 of one application less developed than version 3 of another? The version numbers cannot be used for this kind of qualitative or quantitative comparison. It is entirely possible that higher version numbers can have fewer features and more bugs than older versions. The numbers exist solely to differentiate and organize sequential revisions of software.

For the latest development version of the kernel at the time of writing, for example, the kernel version number from the Linux developers is 2.6.35.3. Ubuntu 10.10 ships with a recent version of 2.6.35 with Ubuntu specific patches applied. It will receive consistent updates throughout the release’s lifecycle.

The kernel version can be broken down into four sections:

- **major version**—This is the major version number, now at 2.
- **minor version**—This is the minor version number, now at 6.
- **sublevel number**—This number indicates the current iteration of the kernel; here it is number 15.
- **extraversion level**—This is the number representing a collection of patches and additions made to the kernel by the Ubuntu engineers to make the kernel work for them (and you). Each collection is numbered, and the number is indicated here in the kernel name. From our preceding example, it is 23.

Typing `uname -r` at the command prompt displays your current kernel version:

```
matthew@seymour:~$ uname -r
2.6.35-14-generic
```

### Obtaining the Kernel Sources

The Linux kernel has always been freely available to anyone who wants it. If you just want to recompile the existing kernel, install the `linux-source` package from the Ubuntu repositories. To get the very latest “vanilla” version, open an FTP connection to `ftp.kernel.org` using your favorite FTP client and log in as anonymous. Because you are interested in the 2.6 kernel, change directories to `/pub/linux/kernel/v2.6`. The latest stable kernel as of this writing is 2.6.35.

**NOTE**

`ftp.kernel.org` receives more than its share of requests for download. It is considered a courtesy to use a mirror site to reduce the traffic that `ftp.kernel.org` bears. `www.kernel.org/mirrors/` has a list of all mirrors around the world. Find one close to your geographic location and substitute that address for `ftp.kernel.org`.
A number of different entries are on the FTP archive site for each kernel version, but because you are interested only in the full kernel, it is necessary to get the full package of source code: for example, linux-2.6.35.bz2.

The .bz2 extension is applied by the bzip2 utility, which has better compression than gzip.

After it is downloaded, move the package to a directory other than /usr/src and unpack it. The bzip2 unpack command is tar -xjvf linux-2.6.35.tar.bz2. After it is unpacked, the package will create a new directory, linux-2.6.35. Copy it to /usr/src or move it there. Then, create a symbolic link of linux-2.6 to linux-2.6.35 (otherwise, some scripts will not work). Here is how to create the symbolic link:

```
matthew@seymour:~$ sudo rm /usr/src/linux-2.6
matthew@seymour:~$ sudo ln -s /usr/src/linux-2.6.35 /usr/src/linux-2.6
```

By creating a symbolic link to /usr/src/linux-2.6, it is possible to allow multiple kernel versions to be compiled and tailored for different functions: You will just change the symbolic link to the kernel directory you want to work on.

---

**CAUTION**

The correct symbolic link is critical to the operation of make. Always have the symbolic link point to the version of the kernel sources you are working with.

---

**Patching the Kernel**

It is possible to patch a kernel to the newest Linux kernel version as opposed to downloading the entire source code. This choice can be beneficial for those who are not using a high-speed broadband connection. Whether you are patching existing sources or downloading the full source, the end results will be identical.

Patching the kernel is not a mindless task. It requires the user to retrieve all patches from the current version to the version the user wants to upgrade to. For example, if you are currently running 2.6.30 (and have those sources) and want to upgrade to 2.6.35, you must retrieve the 2.6.31 and 2.6.32 patch sets, and so on. After they are downloaded, these patches must be applied in succession to upgrade to 2.6.35. This is more tedious than downloading the entire source, but useful for those who keep up with kernel hacking and want to perform incremental upgrades to keep their Linux kernel as up-to-date as possible.

To patch up to several versions in a single operation, you can use the patch-kernel script located in the kernel source directory for the kernel version you currently use. This script applies all necessary version patches to bring your kernel up to the latest version.

The format for using the patch-kernel script looks like this:

```
patch-kernel source_dir patch_dir stopversion
```

The source directory defaults to /usr/src/linux if none is given, and the patch_dir defaults to the current working directory if one is not supplied.
For example, assume that you have a 2.6.33 kernel code tree that needs to be patched to the 2.6.35 version. The 2.6.34 and 2.6.35 patch files have been downloaded from ftp.kernel.org and are placed in the /patch directory in the source tree. You issue the following command in the /usr/src/linux-2.6 directory:

```
matthew@seymour:$ sudo scripts/patch-kernel /usr/src/linux-2.6.33
```

Each successive patch file is applied, eventually creating a 2.6.35 code tree. If any errors occur during this operation, files named xxx# or xxx.rej are created, where xxx is the version of patch that failed. You will have to resolve these failed patches manually by examining the errors and looking at the source code and the patch. An inexperienced person will not have any success with this because you need to understand C programming and kernel programming to know what is broken and how to fix it. Because this was a stock 2.6.33 code tree, the patches were all successfully applied without errors. If you are attempting to apply a nonstandard third-party patch, the patch might likely fail.

When you have successfully patched the kernel, you are ready to begin compiling this code tree as if we started with a fresh, stock 2.6.35 kernel tree.

**USING THE PATCH COMMAND**

If you have a special, nonstandard patch to apply—such as a third-party patch for a commercial product, for example—you can use the patch command rather than the special patch-kernel script that is normally used for kernel source updates. Here are some quick steps and an alternative method of creating patched code and leaving the original code alone.

1. Create a directory in your home directory and name it something meaningful, like mylinux.
2. Copy the pristine Linux source code there with
   ```
cp -ravd /usr/src/linux-2.6/* ~/mylinux
   ```
3. Copy the patch file to that same directory with
   ```
cp patch_filename ~/mylinux
   ```
4. Change to the ~/mylinux directory with
   ```
cd ~/mylinux
   ```
5. Apply the patch with
   ```
   patch -p1 < patch_filename > mypatch.log 2>&1
   ```
   (This last bit of code saves the message output to a file so that you can look at it later.)
6. If the patch applies successfully, you are done and have not endangered any of the pristine source code. In case the newly patched code does not work, you will not have to reinstall the original, pristine source code.
7. Copy your new code to /usr/src and make that special symbolic link described elsewhere in the chapter.
Compiling the Kernel

If you want to update the kernel from new source code you have downloaded, or you have applied a patch to add new functionality or hardware support, you will need to compile and install a new kernel to actually use that new functionality. Compiling the kernel involves translating the kernel's contents from human-readable code to binary form. Installing the kernel involves putting all the compiled files where they belong in /boot and /lib and making changes to the bootloader.

The process of compiling the kernel is almost completely automated by the make utility like the process of installing. By providing the necessary arguments and following the steps covered next, you can recompile and install a custom kernel for your use.

Here are the steps to compile and configure the kernel:

1. Do not delete your current kernel, so that you will have a backup that you can use to boot if there is a problem with the one you compile.
2. Apply all patches, if any, so that you have the features you desire. See the previous section for details.
3. Back up the .config file, if it exists, so that you can recover from the inevitable mistake. Use the following cp command:
   
   ```
   matthew@seymour:~$ sudo cp .config .config.bak
   ```

   **NOTE**

   If you are recompiling the Ubuntu default kernel, the /usr/src/linux-2.6/configs directory contains several versions of configuration files for different purposes. Ubuntu provides a full set of .config files in the subdirectory configs, all named for the type of system they were compiled for. If you want to use one of these default configurations as the basis for a custom kernel, simply copy the appropriate file to /usr/src/linux-2.6 and rename it .config.

4. Run the `make mrproper` directive to prepare the kernel source tree, cleaning out any old files or binaries.
5. Restore the .config file that the command `make mrproper` deleted, and edit the Makefile to change the EXTRAVERSION number.

   **NOTE**

   If you want to keep any current version of the kernel that was compiled with the same code tree, manually edit the Makefile with your favorite text editor and add some unique string to the EXTRAVERSION variable. You can use any description you prefer.
6. Modify the kernel configuration file using `make config`, `make menuconfig`, or `make xconfig`—we recommend the latter.

7. Run `make dep` to create the code dependencies used later in the compilation process.

**TIP**

If you have a multiprocessor machine, you can use both processors to speed the make process by inserting `-jx` after the `make` command, where as a rule of thumb, `x` is one more than the number of processors you have. You might try a larger number and even try this on a single processor machine (we have used `-j8` successfully on an SMP machine); it will only load up your CPU. For example,

```bash
matthew@seymour:~$ sudo make -j3 bzImage
```

All the make processes except `make dep` will work well with this method of parallel compiling.

8. Run `make clean` to prepare the sources for the actual compilation of the kernel.

9. Run `make bzImage` to create a binary image of the kernel.

**NOTE**

Several choices of directives exist, although the most common ones are the following:

- `zImage`—This directive compiles the kernel, creating an uncompressed file called `zImage`.
- `bzImage`—This directive creates a compressed kernel image necessary for some systems that require the kernel image to be under a certain size for the BIOS to be able to parse them; otherwise, the new kernel will not boot. It is the most commonly used choice. However, the Ubuntu kernel compiled with `bzImage` is still too large to fit on a floppy, so a smaller version with some modules and features removed is used for the boot floppies. Ubuntu recommends that you boot from the rescue CD-ROM.
- `bzDisk`—This directive does the same thing as `bzImage`, but it copies the new kernel image to a floppy disk for testing purposes. This is helpful for testing new kernels without writing kernel files to your hard drive. Make sure that you have a floppy disk in the drive because you will not be prompted for one.

10. Run `make modules` to compile any modules your new kernel needs.

11. Run `make modules_install` to install the modules in `/lib/modules` and create dependency files.

12. Run `make install` to automatically copy the kernel to `/boot`, create any other files it needs, and modify the bootloader to boot the new kernel by default.

13. Using your favorite text editor, verify the changes made to `/etc/lilo.conf` or `/boot/grub/grub.conf`; fix if necessary and rerun `/sbin/lilo` if needed.
14. Reboot and test the new kernel.

15. Repeat the process if necessary, choosing a Configuration Interface.

Over time, the process for configuring the Linux kernel has changed. Originally, you configured the kernel by responding to a series of prompts for each configuration parameter (this is the make config utility described shortly). Although you can still configure Linux this way, most users find this type of configuration confusing and inconvenient; moving back through the prompts to correct errors, for instance, is impossible.

The make config utility is a command-line tool. The utility presents a question regarding kernel configuration options. The user responds with a Y, N, M, or ?. (It is not case sensitive.) Choosing M configures the option to be compiled as a module. A response of ? displays context help for that specific options, if available. (If you choose ? and no help is available, you can turn to the vast Internet resources to find information.) We recommend that you avoid the make config utility, shown in Figure 36.1.

![Figure 36.1 The make config utility in all its Spartan glory.](image)

If you prefer to use a command-line interface, you can use make menuconfig to configure the Linux kernel. menuconfig provides a graphical wrapper around a text interface. Although it is not as raw as make config, menuconfig is not a fancy graphical interface either; you cannot use a mouse, but must navigate through it using keyboard commands. The same information presented in make config is presented by make menuconfig, but as you can see in Figure 36.2, it looks a little nicer. Now, at least, you can move back and forth in the selection process in case you change your mind or have made a mistake.

In make menuconfig, you use the arrow keys to move the selector up and down and the spacebar to toggle a selection. The Tab key moves the focus at the bottom of the screen to either Select, Exit, or Help.

If a graphical desktop is not available, menuconfig is the best you can do. However, both menuconfig and xconfig (see the following explanation of each) offer an improvement over editing the .config file directly. If you want to configure the kernel through a true
graphical interface—with mouse support and clickable buttons—make xconfig is the best configuration utility option. To use this utility, you must have the X Window System running. The application xconfig is really nothing but a Tcl/Tk graphics widget set providing borders, menus, dialog boxes, and the like. Its interface is used to wrap around data files that are parsed at execution time. Figure 36.3 shows the main menu of xconfig.

FIGURE 36.2 The make menuconfig utility, a small improvement over make config.

After loading this utility, you use it by clicking each of the buttons that list the configuration options. Each button you click opens another window that has the detail configuration options for that subsection. Three buttons are at the bottom of each window: Main Menu, Next, and Prev(ious). Clicking the Main Menu button closes the current window and displays the main window. Clicking Next takes you to the next configuration section.
When configuring a kernel from scratch, click the button labeled Code Maturity Level Options, and then continue to click the Next button in each subsection window to proceed through all the kernel configuration choices. When you have selected all options, the main menu is again displayed. The buttons on the lower right of the main menu are for saving and loading configurations. Their functions are self-explanatory. If you just want to have a look, go exploring! Nothing will be changed if you elect not to save it.

If you are upgrading kernels from a previous release, it is not necessary to go through the entire configuration from scratch. Instead, you can use the directive `make oldconfig`; it uses the same text interface that `make config` uses, and it is noninteractive. It will just prompt for changes for any new code.

### Using xconfig to Configure the Kernel

For simplicity's sake, during this brisk walk-through, we will assume that you are using `make xconfig`. Prior to this point, we also assume that you will have completed the first five steps in our kernel compilation checklist shown previously.

As you learned in the preceding section, you configure the kernel using `make xconfig` by making choices in several configuration subsection windows. Each subsection window contains specific kernel options. With hundreds of choices, the kernel is daunting to configure. We cannot really offer you detailed descriptions of which options to choose because your configuration will not match your own system and setup.

Table 36.1 provides a brief description of each subsection’s options so that you can get an idea of what you might encounter. We recommend that you copy your kernel’s `.config` file to `/usr/src/linux-2.6` and run `make xconfig` from there. Explore all the options. As long as you do not save the file, absolutely nothing will be changed on your system.

### TABLE 36.1 Some Kernel Subsections for Configuration

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code maturity level options</td>
<td>Enables development code to be compiled into the kernel even if it has been marked as obsolete or as testing code only. This option should be used only by kernel developers or testers because of the possible unusable state of the code during development.</td>
</tr>
<tr>
<td>General setup</td>
<td>This section contains several different options covering how the kernel talks to the BIOS, whether it should support PCI or PCMCIA, whether it should use APM or ACPI, and what kind of Linux binary formats will be supported. Contains several options for supporting kernel structures necessary to run binaries compiled for other systems directly without recompiling the program.</td>
</tr>
<tr>
<td>Loadable module support</td>
<td>Determines whether the kernel enables drivers and other nonessential code to be compiled as loadable modules that can be loaded and unloaded at runtime. This option keeps the basic kernel small so that it can run and respond more quickly; in that regard, choosing this option is generally a good idea.</td>
</tr>
</tbody>

<tr>
<td>Profiling support</td>
<td>Profiling kernel behavior to aid in debugging and development.</td>
</tr>
</tbody>
</table>
After you select all the options you want, you can save the configuration file and continue with Step 7 in the kernel compiling checklist shown earlier.

### Creating an Initial RAM Disk Image

If you require special device drivers to be loaded in order to mount the root file system (for SCSI drives, network cards, or exotic file systems, for example), you must create an initial RAM disk image named `/boot/initrd.img`. For most users, it is not necessary to create this file, but if you are not certain, it really does not hurt. To create an `initrd.img` file, use the shell script `/sbin/mkinitrd`.

The format for the command is the following, where `file_name` is the name of the image file you want created:

```
/sbin/mkinitrd file_name kernel_version
```

`mkinitrd` looks at `/etc/fstab`, `/etc/modprobe.conf`, and `/etc/raidtab` to obtain the information it needs to determine which modules should be loaded during boot. For our system, we use

```
matthew@seymour:~$ sudo mkinitrd initrd-2.6.7-1.img 2.6.7-1
```

### When Something Goes Wrong

Several things might go wrong during a kernel compile and installation, and several clues will point to the true problem. You will see error messages printed to the screen, and some error messages will be printed to the file `/var/log/messages`, which can be examined with a text editor. If you have followed our directions for patching the kernel, you will need to examine a special error log as well. Do not worry about errors because many problems are easily fixed with some research on your part. Some errors may be unfixable, however, depending on your skill level and the availability of technical information.
Errors During Compile

Although it is rare that the kernel will not compile, there is always a chance that something has slipped though the regression testing. Let’s take a look at an example of a problem that might crop up during the compile.

It is possible that the kernel compile will crash and not complete successfully, especially if you attempt to use experimental patches, add untested features, or build newer and perhaps unstable modules on an older system.

At this juncture, you have two options:

- Fix the errors and recompile.
- Remove the offending module or option and wait for the errors to be fixed by the kernel team.

Most users will be unable to fix some errors because of the complexity of the kernel code, although you should not rule out this option. It is possible that someone else discovered the same error during testing of the kernel and developed a patch for the problem: check the Linux kernel mailing list archive. If the problem is not mentioned there, a search on Google might turn up something.

The second option, removing the code, is the easiest and is what most people do in cases in which the offending code is not required. In the case of the NTFS module failing, it is almost expected because NTFS support is still considered experimental and subject to errors. This is primarily because the code for the file system is reverse-engineered instead of implemented via documented standards. Read-only support has gotten better in recent kernels; write support is still experimental.

Finally, should you want to take on the task of trying to fix the problem yourself, this is a great opportunity to get involved with the Linux kernel and make a contribution that could help many others.

If you are knowledgeable about coding and kernel matters, you might want to look in the MAINTAINERS file in the `/usr/src/linux-2.6/` directory of the kernel source and find the maintainer of the code. The recommended course of action is to contact the maintainer to see if the maintainer is aware of the problems you are having. If nothing has been documented for the specific error, submitting the error to the kernel mailing list is an option. The guidelines for doing this are in the README file in the base directory of the kernel source under the section, “If Something Goes Wrong.”

Runtime Errors, Boot Loader Problems, and Kernel Oops

Runtime errors occur as the kernel is loading. Error messages are displayed on the screen or written to the `/var/log/messages` file. Bootloader problems display messages to the screen; no log file is produced. Kernel oops are errors in a running kernel, and error messages are written to the `/var/log/messages` file.

Excellent documentation on the Internet exists for troubleshooting just about every type of error that GRUB2 or the kernel could give during boot. The best way to find this docu-
mentation is to go to your favorite search engine and type in the keywords of the error you received. You will need to adjust the keywords you use as you focus your search.

If you have GRUB problems, the GRUB manual is online at www.gnu.org/software/grub/manual/ and further information is available at https://help.ubuntu.com/community/Grub2.

**TIP**

For best results, go to www.google.com/linux to find all things Linux on the Internet. Google has specifically created a Linux area of its database, which should allow faster access to information on Linux than any other search engine.

As with any new thing, it's worthwhile finding out a bit about its history. Ubuntu is no different, and in this appendix you'll learn a little more about where Linux (and Ubuntu) came from.

What Is Linux?

Linux is the core, or kernel, of a free operating system first developed and released to the world by Linus Benedict Torvalds in 1991. Torvalds, then a graduate student at the University of Helsinki, Finland, is now a Fellow at the Linux Foundation (www.linuxfoundation.org/). He is an engineer and previously worked for the CPU design and fabrication company Transmeta, Inc. before leaving in 2003 to work for Open Source Development Labs (ODSL), a consortium created by many high-tech companies to support Linux development and which has enabled him to focus on the Linux kernel full time. Fortunately for all Linux users, Torvalds chose to distribute Linux under a free software license named the GNU General Public License (GPL).

NOTE

The free online resource Wikipedia has a great biography of Linus Torvalds that examines his life and notable achievements. You can find it at http://en.wikipedia.org/wiki/Linux_Torvalds.

The GNU GPL is the brainchild of Richard M. Stallman, the founder of the Free Software Foundation. Stallman, the
famous author of the Emacs editing environment and GCC compiler system, crafted the GPL to ensure that software that used the GPL for licensing would always be free and available in source-code form. The GPL is the guiding document for Linux and its ownership, distribution, and copyright. Torvalds holds the rights to the Linux trademark, but thanks to a combination of his generosity, the Internet, thousands of programmers around the world, GNU software, and the GNU GPL, Linux will remain forever free and unencumbered by licensing or royalty issues.

### DISTRIBUTION VERSION AND KERNEL NUMBERING SCHEMA

There is a numbering system for Linux kernels, kernel development, and Ubuntu’s kernel versions. Note that these numbers bear no relation to the version number of your Ubuntu Linux distribution. Ubuntu distribution version numbers are assigned by the Ubuntu developers, whereas most of the Linux kernel version numbers are assigned by Linus Torvalds and his legion of kernel developers.

To see the date your Linux kernel was compiled, use the `uname` command with its `-v` command-line option. To see the version of your Linux kernel, use the `-r` option. The numbers, such as 2.6.32-24-generic, represent the major version (2), minor version (6), and patch level (32). The final number (24-generic) is the developer patch level and is assigned by the Ubuntu developers.

Even minor numbers are considered “stable” and generally fit for use in production environments. You will find only stable versions of the Linux kernel included with this book. You can choose to download and install a beta (test) version of the kernel, but this is not recommended for a system destined for everyday use. When used, beta kernels are installed by developers to test support of new hardware or operating system features.

Linux, pronounced “lih-nucks,” is free software. Combining the Linux kernel with GNU software tools—drivers, utilities, user interfaces, and other software such as the X.Org Foundation’s X Window System—creates a Linux distribution. There are many different Linux distributions from different vendors, but many derive from or closely mimic the Debian Linux distribution, on which Ubuntu is founded.

### NOTE

To see just how many distributions are based on Debian Linux, go to www.linux.org/, click Distributions, and search for “Debian-based.” At the time of writing, 38 distributions owe their existence to Debian.

### Why Use Linux?

Millions of clever computer users have been putting Linux to work for more nearly 20 years. Over the past year, many individuals, small office/home office (SOHO) users, businesses and corporations, colleges, nonprofits, and government agencies (local, state, and
Why Use Linux?

Federal) in a number of countries have incorporated Linux with great success. And, today, Linux is being incorporated into many information service/information technology (IS/IT) environments as part of improvements in efficiency, security, and cost savings. Using Linux is a good idea for a number of reasons, including the following:

- Linux provides an excellent return on investment (ROI)—There is little or no cost on a per-seat basis. Unlike commercial operating systems, Linux has no royalty or licensing fees, and a single Linux distribution on CD-ROM or network shared folder can form the basis of an enterprise wide software distribution, replete with applications and productivity software. Custom corporate CD-ROMs can be easily crafted or network shares can be created to provide specific installs on enterprise-wide hardware. This feature alone can save hundreds of thousands, if not millions, of dollars in IS/IT costs—all without the threat of a software audit from the commercial software monopoly or the need for licensing accounting and controls of base operating system installations.

- Linux can be put to work on the desktop—Linux, in conjunction with its supporting graphical networking protocol and interface (the X Window System), has worked well as a consumer UNIX-like desktop operating system since the mid-1990s. The fact that UNIX is ready for the consumer desktop is now confirmed with the introduction, adoption, and rapid maturation of Apple Computer BSD UNIX—based on Mac OS X—supported, according to Apple, by more than 3,000 Mac OS X-specific programs that are known as native applications. This book's disc contains more than 800 software packages, including Internet connection utilities, games, a full office suite, many fonts, and hundreds of graphics applications.

- Linux can be put to work as a server platform—Linux is fast, secure, stable, scalable, and robust. The latest versions of the Linux kernel easily support multiple-processor computers, large amounts of system memory (up to 64GB RAM), individual file sizes in excess of hundreds of gigabytes, a choice of modern journaling file systems, hundreds of process monitoring and control utilities, and the (theoretical) capability to simultaneously support more than four billion users. IBM, Oracle, and other major database vendors all have versions of their enterprise software available for Linux.

- Linux has a low entry and deployment cost barrier—Maintenance costs can also be reduced because Linux works well on a variety of PCs, including legacy hardware, such as some Intel-based 486 and early Pentium CPUs. Although the best program performance will be realized with newer hardware, because clients can be recompiled and optimized for Pentium-class CPUs, base installs can even be performed on lower-end computers or embedded devices with only 8MB of RAM. This feature provides for a much wider user base; extends the life of older working hardware; and can help save money for home, small business, and corporate users.

- Linux appeals to a wide audience in the hardware and software industry—Versions of Linux exist for nearly every CPU. Embedded-systems developers now turn to Linux when crafting custom solutions using ARM, MIPS, and other low-power processors. Linux is the first full operating system available for Intel's Itanium CPU,
as well as the AMD64 group of CPUs; ports have also been available for HP/Compaq’s Alpha and Sun Microsystems SPARC CPUs for some time. PowerPC users regularly use the PPC port of Linux on IBM and Apple hardware.

- Linux provides a royalty-free development platform for cross-platform development—Because of the open-source development model and availability of free, high-quality development tools, Linux provides a low-cost entry point to budding developers and tech industry start-ups.

- Big-player support in the computer hardware industry from such titans as IBM now lends credibility to Linux as a viable platform—IBM has enabled Linux on the company’s entire line of computers, from low-end laptops through “Big Iron” mainframes. New corporate customers are lining up and using Linux as part of enterprise-level computing solutions. It has been used on some of the world’s fastest computers, including IBM’s Blue Gene/L. HP also certifies Linux across a large portion of its hardware offering.

Look forward to even more support as usage spreads worldwide throughout all levels of business in search of lower costs, better performance, and stable and secure implementations.

What Is Ubuntu?

Ubuntu is an operating system based on the Linux kernel; created, improved, refined, and distributed by the Ubuntu Community at www.ubuntu.com/. Ubuntu, sponsored by Canonical Software, is an open-source project supported by a worldwide community of software developers.

Ubuntu is one of the newer Linux distributions currently available today, having released its first version in October 2004. It quickly gained a reputation for ease of installation and use, combined with the slightly wacky code names given to each release. However, Ubuntu itself is based on Debian, which is a much older distribution steeped in respect from the wider Linux community. Ubuntu describes Debian as being the rock on which it is founded, and this is a good way to describe the relationship between the two. It is also worth noting that Debian garnered a reputation for infrequent releases. The move from Debian 3.0 to 3.1 took almost three years, during which time many other Linux distros had moved far ahead of Debian.

Sponsored by Canonical Software and with the formidable resources of Mark Shuttleworth, Ubuntu got off to a great start with version 4.10, the Warty Warthog. From the start, Ubuntu specified clear goals: to provide a distribution that was easy to install and use, that did not overly confuse the user, and that came on a single CD (something increasingly rare these days when a distro can occupy four or five CDs). Releasing every six months, Ubuntu made rapid progress into the Linux community and is now one of the most popular Linux distros across the world.
**UBUNTU VERSIONS**

As mentioned earlier, Ubuntu has chosen some peculiar code names for their releases since the first launch in October 2004. Doing away with the typical version numbering found elsewhere, Ubuntu decided to take the month and year of release and reverse them. Hence, the first release in October 2004 became 4.10, followed quickly by 5.04 (April 2005), 5.10, 6.06LTS, and so on up to the current 10.10.

The version covered in this book was released in October 2010, and thus bears the version number 10.10. What’s even more special about some releases is that they also carries the LTS (Long Term Support) label, meaning that Canonical will support LTS versions for three years on the desktop and a total of five years for the server version after its release. The most recent LTS version was 10.04.

The code names during development are even better: 4.10 was christened the Warty Warthog in recognition that it was a first release, warts and all. The second release, 5.04, was dubbed the Hoary Hedgehog. Things got slightly better with 5.10, code-named the Breezy Badger. 6.06 was announced as the Dapper Drake and was the first Ubuntu distribution to carry the LTS badge. Beyond Dapper, there was the Edgy Eft (6.10) followed by the Feisty Fawn (7.04), and more, up to what was known during development as the maverick meercat (10.10), which is what this book covers.

---

**Ubuntu for Business**

Linux has matured over the years, and features considered essential for use in enterprise-level environments, such as CPU architecture support, file systems, and memory handling, have been added and improved. The addition of virtual memory (the capability to swap portions of RAM to disk) was one of the first necessary ingredients, along with a copyright-free implementation of the TCP/IP stack (mainly due to BSD UNIX being tied up in legal entanglements at the time). Other features quickly followed, such as support for a variety of network protocols.

Ubuntu includes a Linux kernel that can use multiple processors, which allows you to use Ubuntu in more advanced computing environments with greater demands on CPU power. This kernel will support at least 16 CPUs; in reality, however, small business servers typically use only dual-CPU workstations or servers. However, Ubuntu can run Linux on more powerful hardware.

Ubuntu will automatically support your multiple-CPU Intel-based motherboard, and you will be able to take advantage of the benefits of symmetric multiprocessors (SMPs) for software development and other operations. The Linux kernels included with Ubuntu can use system RAM sizes up to 64GB, allow individual file sizes in excess of 2GB, and host the demands of—理论—billions of users.

Businesses that depend on high-availability, large-scale systems can also be served by Ubuntu, along with the specialist commercial support on offer from hundreds of support partners across the world.
However, Ubuntu can be used in many of these environments by customers with widely disparate computing needs. Some of the applications for Ubuntu include desktop support; small file, print, or mail servers; intranet web servers; and security firewalls deployed at strategic points inside and outside company LANs.

Commercial customers will also benefit from Debian’s alliances with several top-tier system builders, including Hewlett-Packard.

Debian itself is also available for multiple architectures, and until recently was developed in tandem on 11 different architectures, from x86 to the older Motorola 680x0 chips (as found in the Commodore Amiga), along with several other architectures.

Small business owners can earn great rewards by stepping off the software licensing and upgrade treadmill and adopting a Linux-based solution. Using Ubuntu not only avoids the need for licensing accounting and the threat of software audits, but also provides viable alternatives to many types of commercial productivity software.

Using Ubuntu in a small business setting makes a lot of sense for other reasons, too, such as not having to invest in cutting-edge hardware to set up a productive shop. Ubuntu easily supports older, or legacy, hardware, and savings are compounded over time by avoiding unnecessary hardware upgrades. Additional savings will be realized because software and upgrades are free. New versions of applications can be downloaded and installed at little or no cost, and office suite software is free.

Ubuntu is easy to install on a network and plays well with others, meaning it works well in a mixed-computing situation with other operating systems such as Windows, Mac OS X, and, of course, UNIX. A simple Ubuntu server can be put to work as an initial partial solution or made to mimic file, mail, or print servers of other operating systems. Clerical staff should quickly adapt to using familiar Internet and productivity tools, while your business gets the additional benefits of stability, security, and a virus-free computing platform.

By carefully allocating monies spent on server hardware, a productive and efficient multiuser system can be built for much less than the cost of comparable commercial software. Combine these benefits with support for laptops, PDAs, and remote access, and you will find that Ubuntu supports the creation and use of an inexpensive yet efficient work environment.

**Ubuntu in Your Home**

Ubuntu installs a special set of preselected software packages onto your hard drive; these are suitable for small office/home office (SOHO) users. This option provides a wealth of productivity tools for document management, printing, communication, and personal productivity.

The standard installation requires nearly 2GB of hard drive space but should easily fit onto smaller hard drives in older Pentium-class PCs. The install also contains administrative tools, additional authoring and publishing clients, a variety of editors, a GNOME-based X11 desktop, support for sound, graphics editing programs, and graphical and text-based Internet tools.
64-Bit Ubuntu

Advances in computing saw the introduction of 64-bit x86-compatible CPUs from AMD in the spring of 2003. Intel’s EM64T extensions for x86, which largely mirror the advances made by AMD, have further increased the availability of commodity x86-64 hardware.

Ubuntu fully supports AMD64 processors, and you are encouraged to use the 64-bit version of Ubuntu to get the maximum from these advanced processors.

As far as the Intel Itanium architecture goes, unfortunately Ubuntu does not currently support ia64. However, you may want to investigate Debian, which is available for the ia64 platform and several others.

Getting the Most from Ubuntu and Linux Documentation

Nearly all commercial Linux distributions include shrink-wrapped manuals and documentation covering installation and configuration. You will not find official documentation included on the DVD provided with this book. However, you can read or get copies of assorted manuals or topic discussions online at www.ubuntu.com/. There you will find the links to various Ubuntu documentation projects.

Documentation for Ubuntu (and many Linux software packages) is distributed and available in a variety of formats. Some guides are available in Portable Document Format (PDF) and can be read using Adobe’s Acrobat Reader for Linux or the evince client. Guides are also available as bundled HTML files for reading with a web browser such as links, KDE’s Konqueror, GNOME’s Epiphany, or Firefox. Along with these guides, Ubuntu provides various tips, frequently asked questions (FAQs), and HOWTO documents.

You will find traditional Linux software package documentation, such as manual pages, under the /usr/share/man directory, with documentation for each installed software package under /usr/share/doc.

Linux manual pages are compressed text files containing succinct information about how to use a program. Each manual page generally provides a short summary of a command’s use, a synopsis of command-line options, an explanation of the command’s purpose, potential caveats or bugs, the name of the author, and a list of related configuration files and programs.

For example, you can learn how to read manual pages by using the man command to display its own manual page, as follows:

    matthew@seymour:~$ man man

After you press Enter, a page of text appears on the screen or in your window on the desktop. You can then scroll through the information using your keyboard’s cursor keys, read, and then press the Q key to quit reading.

Many of the software packages also include separate documents known as HOWTOs that contain information regarding specific subjects or software.
If the HOWTO documents are simple text files in compressed form (with filenames ending in .gz), you can easily read the document by using the zless command, which is a text pager that enables you to scroll back and forth through documents. (Use the less command to read plain-text files.) You can start the command by using less, followed by the complete directory specification and name of the file, or pathname, like this:

```
matthew@seymour:-$ less /usr/share/doc/httpd-2.0.50/README
```

To read a compressed version of this file, use the zless command in the same way:

```
matthew@seymour:-$ zless /usr/share/doc/attr-2.4.1/CHANGES.gz
```

After you press Enter, you can scroll through the document using your cursor keys. Press the Q key to quit.

If the HOWTO document is in HTML format, you can simply read the information using a web browser, such as Firefox. Or if you are reading from a console, you can use the links or lynx text-only web browsers, like this:

```
matthew@seymour:-$ links /usr/share/doc/stunnel-4.0.5/stunnel.html
```

The links browser offers drop-down menus, accessed by clicking at the top of the screen. You can also press the Q key to quit.

If the documentation is in PostScript format (with filenames ending in .ps), you can use the gv client to read or view the document like this:

```
matthew@seymour:-$ gv /usr/share/doc/iproute-2.4.7/ip-crefs.ps
```

Finally, if you want to read a document in Portable Document Format (with a filename ending in .pdf), use the evince client, as follows:

```
matthew@seymour:-$ evince /usr/share/doc/xfig/xfig-howto.pdf
```

**NOTE**

This book was developed and written using the standard Ubuntu CD. You can use the disc included with this book for your install or download your own copy, available as ISO9660 images (with filenames ending in .iso), and burn it onto a 700MB CD-R or a DVD. You can also order prepressed CDs directly from Ubuntu at http://shipit.ubuntu.com.

Along with the full distribution, you will get access to the complete source code to the Linux kernel and source for all software in the distribution—more than 55 million lines of C and nearly 5 million lines of C++ code. Browse to www.ubuntu.com/download/ to get started.

---

**Ubuntu Developers and Documentation**

If you are interested in helping with Ubuntu, you can assist in the effort by testing beta releases (known as preview releases, and usually named after the animal chosen for the release name), writing documentation, and contributing software for the core or contributed software repositories. You should have some experience in installing Linux
distributions, a desire to help with translation of documentation into different languages, or be able to use various software project management systems, such as CVS.

Mailing lists are also available as an outlet or forum for discussions about Ubuntu. The lists are categorized. For example, general users of Ubuntu discuss issues on the ubuntu-users mailing list. Beta testers and developers via the ubuntu-devel, and documentation contributors via the ubuntu-doc mailing list. You can subscribe to mailing lists by selecting the ones you are interested in at http://lists.ubuntu.com/mailman/listinfo/. Be warned; some of the mailing lists have in excess of 200 to 300 emails per day!

**Reference**

- [www-1.ibm.com/linux/](http://www-1.ibm.com/linux/)—Information from IBM regarding its efforts and offerings of Linux hardware, software, and services.
- [www.tldp.org/](http://www.tldp.org/)—The definitive starting point for the latest updates to generic Linux FAQs, guides, and HOWTO documents.
- [www.justlinux.com/](http://www.justlinux.com/)—One site to which new Linux users can browse to learn more about Linux.
- [www.ubuntuforums.org/](http://www.ubuntuforums.org/)—A popular site that allows users to communicate and support each other with questions and problems.
Ubuntu enjoys a wealth of Internet support in the form of websites with technical information, specific program documentation, targeted whitepapers, bug fixes, user experiences, third-party commercial technical support, and even free versions of specialized, fine-tuned clone distributions. This appendix lists many of the supporting websites, FTP repositories, Usenet newsgroups, and electronic mailing lists that you can use to get more information and help with your copy of Ubuntu.

IF YOU NEED HELP 24/7

Whether you are an individual, small business, corporate, or enterprise-level Ubuntu user, don’t forget that you can always turn to the source, Canonical, or third-party companies who supply Ubuntu support for commercial technical support on a 24/7 onsite basis, by phone, by electronic mail, or even on a per-incident basis. Canonical Software offers a spectrum of support options for its software products. You can read more about support options from the Ubuntu website: www.ubuntu.com/support.

The appendix is divided into the following sections:

- Websites with Linux information arranged by category
- Usenet newsgroups pertaining to Linux
- Mailing lists providing Linux user and developer discussions
- Internet Relay Chat groups for Linux information
This appendix also lists websites that might be of general interest when using Ubuntu or specific components such as Xorg. Every effort has been made to ensure the accuracy of the URLs, but keep in mind that the Internet is always in flux!

**KEEP UP-TO-DATE**

Keeping informed about bug fixes, security updates, and other errata is critical to the success and health of an Ubuntu system. To keep abreast of the most important developments when using Ubuntu, be sure to register with the Ubuntu Announcements mailing list. From there, you will learn which updates have been issued and what has been fixed as a result. Go to https://lists.ubuntu.com/mailman/listinfo/ubuntu-security-announce to register for this mailing list. You should also keep an eye out for Update Manager notifications in order to keep up with bug fixes, new software packages, and security updates.

---

**Websites and Search Engines**

Literally thousands of websites exist with information about Linux and Ubuntu. The key to getting the answers you need right away involves using the best search engines and techniques. Knowing how to search can mean the difference between frustration and success when troubleshooting problems. This section provides some Internet search tips and lists Ubuntu- and Linux-related sites sorted by various topics. The lists are not comprehensive, but have been checked and were available at the time of this writing.

**Web Search Tips**

Troubleshooting problems with Linux by searching the Web can be an efficient and productive way to get answers to vexing problems. One of the most basic rules for conducting productive searches is to use specific search terms to find specific answers. For example, if you simply search for “Ubuntu Linux,” you will end up with too many links and too much information. If you search for “Ubuntu sound,” however, you are more likely to find the information you need. If you’ve received an error message, use it; otherwise, use the Linux kernel diagnostic message as your search criterion.

Other effective techniques include the following:

- Using symbols in the search string, such as the plus sign (+) to force matches of web pages containing both strings (if such features are supported by the search engine used by web search site)
- Searching within returned results
- Sorting results (usually by date to get the latest information)
- Searching for related information
- Stemming searches; for example, specifying returns for not only “link” but also “linking” and “linked”
Invest some time and experiment with your favorite search engine’s features—the result will be more productive searches. In addition to sharpening your search skills, also take the time to choose the best search engine for your needs.

**Google Is Your Friend**

Some of the fastest and most comprehensive search engines on the Web are powered by Linux, so it makes sense to use the best available resources. Out of the myriad number of websites with search engines, http://google.com stands out from the crowd, with millions of users per month. The site uses advanced hardware and software to bring speed and efficiency to your searches. If you are looking for specific Linux answers, take advantage of Google’s Linux page at http://google.com/linux.

Why is Google (named after a math number) so powerful? You can get a quick overview from the Google folks at www.google.com/corporate/tech. Part of its success is because of great algorithms, good programming, and simple interface design; but most users really seem to appreciate Google’s uncanny capability to provide links to what you are looking for in the first page of a search return. Google’s early success was also assured because the site ran its search engine on clusters of thousands of PCs running a version of Red Hat Linux! It is also rumored that an Ubuntu-based distribution is in use on desktops at Google, with the informal moniker of Goobuntu.

Google has the largest database size of any search engine on the Web, with many billions of web pages searched and indexed. The database size is important because empty search results are useless to online users, and the capability to return hits on esoteric subjects can make the difference between success and failure or satisfaction and frustration.

To get a better idea of what Google can offer you, browse to www.google.com/options/. You will find links to many services and tools covering specialized searches, databases, information links, translators, and other helpful browsing tools.

**Ubuntu Package Listings**

You can quickly and easily view a list of the installed packages on your Ubuntu system, along with a short description of each package, by using the Ubuntu Software Center or Synaptic. Each also shows you descriptions of each package so you can decide whether you want it installed. For more information see Chapter 32, “Managing Software.”

**Certification**

Linux certification courses are part of the rapidly growing information technology training industry. Hundreds of different vendors now offer courses about and testing of Linux skill sets. However, because Linux is open-source software, there are no formal rules or mandates concerning what knowledge or level of expertise is required for certification. If you are interested in certification and want to pursue a career or obtain employment with a company using Linux, you really should seek training. You can find a good list of companies that can provide training at www.ubuntu.com/support/training/, along with other resources.
Commercial Support

Commercial support for Ubuntu is an essential ingredient to the success of Linux in the corporate and business community. Although hundreds, if not thousands, of consultants well versed in Linux and UNIX are available on call for a fee, here is a short list of the best-known Linux support providers:

- [www.ubuntu.com/support/services](http://www.ubuntu.com/support/services)—Go straight to the source for a range of support options. You can get help on Ubuntu direct from Canonical software, or from a local support provider.

- [www.hp.com/linux](http://www.hp.com/linux)—HP offer a comprehensive package of Linux services and hardware that cover almost everything that you would want to do, including consultancy, business solutions, and hardware specification and implementation.

- [www.ibm.com/linux/](http://www.ibm.com/linux/)—Linux services offered by IBM include e-business solutions, open-source consulting, database migration, clustering, servers, and support.

In addition to service-oriented support companies, nearly every commercial distributor of Linux has some form of easily purchased commercial support. There are various ways in which to take advantage of support services (such as remote management, onsite consulting, device driver development, and so on), but needs will vary according to customer circumstances and installations.

THE BENEFITS OF JOINING A LINUX USER GROUP

Join a local Linux Users Group (LUG)! Joining and participating in a local LUG has many benefits. You will be able to get help, trade information, and learn many new and wonderful things about Linux. Most LUGs do not have membership dues, and many often sponsor regular lectures and discussions from leading Linux, GNU, and open-source experts. For one great place to start, browse to [www.tux.org/luglist.html](http://www.tux.org/luglist.html). For Ubuntu specific groups, check out Ubuntu Local Community, or LoCo Teams at [http://loco.ubuntu.com/](http://loco.ubuntu.com/).

Documentation

Nearly all Linux distributions include thousands of pages of documentation in the form of manual pages, HOWTO documents (in various formats, such as text and HTML), mini-HOWTO documents, or software package documentation (usually found under the `/usr/share/doc/` directory). However, the definitive site for reading the latest versions of these documents is the Linux Documentation Project, found at [www.tldp.org](http://www.tldp.org).
Linux Guides

If you are looking for more extensive and detailed information concerning a Linux subject, try reading one of the many Linux guides. These guides, available for a number of subjects, dwell on technical topics in more detail and at a more leisurely pace than a HOWTO. You can find copies of:

- “Advanced Bash-Scripting Guide,” by Mendel Cooper; a guide to shell scripting using bash
- “LDP Author Guide,” by Mark F. Komarinski; how to write LDP documentation
- “Linux Administration Made Easy,” by Steve Frampton
- “Linux Consultants Guide,” by Joshua Drake; a worldwide listing of commercial Linux consultants
- “Linux from Scratch,” by Gerard Beekmans; creating a Linux distribution from software
- “Linux Kernel Module Programming Guide,” by Peter J Salzman, Michael Burian, and Ori Pomerantz; a good guide to building 2.4 and 2.6 series modules
- “Securing and Optimizing Linux,” by Gerhard Mourani
- Linux certification

Ubuntu

The best place to start for Ubuntu-specific information are Ubuntu-focused websites. Where better to start than the main website for the distribution and the official web forums? While these are not the only official Ubuntu resources, they are the most likely to be immediately useful. Others are easily found under the Support tab on the Ubuntu.com website.

- www.ubuntu.com—Home page for Ubuntu, Canonical’s community-based free Linux distribution. Ubuntu is the main release of this Linux distribution and includes thousands of software packages that form the core of an up-to-date, cutting-edge Linux-based desktop. You can also find links to the other *buntus, such as Kubuntu, Xubuntu, and edubuntu.
- www.ubuntuforums.org—A good place to go if you need specific Ubuntu support.

Mini-CD Linux Distributions

Mini-CD Linux distributions are used for many purposes. Some distributions are used to boot to a read-only firewall configuration; some are used to provide as complete a rescue environment as possible; whereas others are used to either install or help jumpstart an
install of a full distribution. Mini-CDs are available in a variety of sizes, such as 3CD-Rs (or CD-RW) with sizes ranging from 185MB to 210MB. You can also download an .iso image and create a Linux bootable business card, typically fitting on a 40MB or 50MB credit-card-size CD-R. (Consider using a mini–CD-RW, especially if you want to upgrade your distribution often.) Here are some links to these distributions:

- www.lnx-bbc.com—Home page for the Linux BBC, a 40MB image hosting a rather complete live Linux session with X, a web browser, and a host of networking tools.
- www.smoothwall.org—The 69MB SmoothWall distribution is used to install a web-administered firewall, router, or gateway with SSH, HTTP, and other services.

Various Intel-Based Linux Distributions

Choosing a Linux distribution (distro) for an Intel-based PC is generally a matter of personal preference or need. Many Linux users prefer Red Hat's distro because of its excellent support, commercial support options, and widespread use around the world. However, many different Linux distributions are available for download. One of the best places to start looking for a new distro or new version of your favorite distro is www.distrowatch.com:

- www.debian.org—The Debian Linux distribution, consisting only of software distributed under the GNU GPL license. Ubuntu, itself, is based upon Debian.
- www.slackware.com—Home page for download of the newest version of one of the oldest Linux distributions, Slackware.
- www.opensuse.org—Home page for SUSE Linux.
- www.redhat.com/—One of the most used distributions in the corporate and server world.

PowerPC-Based Linux Distributions

PowerPC processors were created by an alliance between Apple, IBM, and Motorola. They have been used extensively in video game consoles, embedded applications, and were the processors used in Apple's Macintosh computers from 1994 to 2006.

- http://penguinppc.org/—Home page for the PowerPC GNU/Linux distribution
- www.yellowdoglinux.com—Home page for Terra Soft Solutions's Yellow Dog Linux for the PowerPC, which is based on Fedora

Linux on Laptops and PDAs

One of the definitive sites for getting information about running Linux on your laptop is Kenneth Harker's Linux Laptop site. Although not as actively updated as in the past, this site (www.linux-laptop.net) still contains the world's largest collection of Linux and laptop information, with links to user experiences and details concerning specific laptop models.
Another site to check is Werner Heuser’s Tuxmobil-Mobile UNIX website at www.tuxmobil.org. You will find links to information such as IrDA, Linux PDAs, and cell phones. Linux Zaurus PDA users can browse to www.openzaurus.org to download a complete open-source replacement operating system for the Zaurus 5000 and 5500 models.

The X Window System

Although much technical information is available on the Internet regarding the X Window System, finding answers to specific questions when troubleshooting can prove problematic. If you are having a problem using X, first try to determine whether the problem is software or hardware related. When searching or asking for help (such as on Usenet’s comp.os.linux.x newsgroup, which you can access through Google’s Groups link; see the next section for other helpful Linux newsgroups), try to be as specific as possible. Some critical factors or information needed to adequately assess a problem include the Linux distribution in use; the kernel version used; the version of X used; the brand, name, and model of your video card; the names, brands, and models of your monitor and other related hardware.

Definitive technical information regarding X is available from www.X.org.

Usenet Newsgroups

Linux-related Usenet newsgroups are another good source of information if you’re having trouble using Linux. If your ISP does not offer a comprehensive selection of Linux newsgroups, you can browse to http://groups.google.com/.

The primary Linux and Linux-related newsgroups are as follows:

- alt.os.linux.dial-up—Using PPP for dial-up
- alt.os.linux.mandriva—All about Mandriva Linux
- alt.os.linux.slackware—Using Slackware Linux
- alt.os.linux.ubuntu—Using Ubuntu Linux
- comp.os.linux.advocacy—Heated discussions about Linux and other related issues
- comp.os.linux.alpha—Using Linux on the Alpha CPU
- comp.os.linux.announce—General Linux announcements
- comp.os.linux.answers—Releases of new Linux FAQs and other information
- comp.os.linux.development.apps—Using Linux development tools
- comp.os.linux.development.system—Building the Linux kernel
- comp.os.linux.embedded—Linux embedded device development
- comp.os.linux.hardware—Configuring Linux for various hardware devices
- comp.os.linux.m68k—Linux on Motorola’s 68K-family CPUs
Mailing Lists

Mailing lists are interactive or digest-form electronic discussions about nearly any topic. To use a mailing list, you must generally send an email request to be subscribed to the list, and then verify the subscription with a return message from the master list mailer. After subscribing to an interactive form of list, each message sent to the list will appear in your email inbox. However, many lists provide a digest form of subscription in which a single- or half-day’s traffic is condensed in a single message. The digest form is generally preferred unless you have set up electronic mail filtering.

The main Ubuntu mailing lists are detailed here, but there are quite a few Linux-related lists. You can search for nearly all online mailing lists by using a typical mailing list search web page, such as the one at www.lsoft.com/lists/list_q.html.

GNOME AND KDE MAILING LISTS

GNOME users and developers should know that more than two dozen mailing lists are available through http://mail.gnome.org/. KDE users will also benefit by perusing the KDE-related mailing lists at www.kde.org/mailinglists.html.
**Ubuntu Project Mailing Lists**

The Ubuntu Project is always expanding, as many new users continue to find Ubuntu for the first time. You will find many other knowledgeable users with answers to your questions by participating in one of Ubuntu’s mailing lists. The lists are focused on using, testing, and developing and participating in Ubuntu’s development:

- [http://lists.ubuntu.com/mailman/listinfo/ubuntu-devel](http://lists.ubuntu.com/mailman/listinfo/ubuntu-devel)—Queries and reports from developers and testers of Ubuntu test releases

**Internet Relay Chat**

*Internet Relay Chat (IRC)* is a popular form and forum of communication for many Linux developers and users because it allows an interactive, real-time exchange of information and ideas. To use IRC, you must have an IRC client and the address of a network and server hosting the desired chat channel for your discussions.

You can use the [irc.freenode.net](http://irc.freenode.net) IRC server, or one listed at [www.freenode.net/](http://www.freenode.net/) to chat with other Ubuntu users. Some current channels are as follows:

- #Ubuntu—General chat about Ubuntu
- #edubuntu—General chat about EdUbuntu
- #xubuntu—General chat about Xubuntu
- #kubuntu—General chat about Kubuntu

For more channels to look at, head over to [https://help.ubuntu.com/community/InternetRelayChat](https://help.ubuntu.com/community/InternetRelayChat) for an exhaustive list of “official” channels.

However, Google can help you find other channels to explore. Enter the distro name and IRC into the search options to retrieve information on any IRC channels relevant to your requirements. To get help with getting started with IRC, browse to [www.irchelp.org/](http://www.irchelp.org/). Some of the channels of interest might be

- #linux—General discussions about Linux.
- #linuxhelp—A help chat discussion for new users.
- Most IRC networks provide one or more Linux channels, although some providers require signup and registration before you can access any chat channel.

Your purchase of *Ubuntu Unleashed 2011 Edition: Covering 10.10 and 11.04* includes access to a free online edition for 45 days through the Safari Books Online subscription service. Nearly every Sams book is available online through Safari Books Online, along with more than 5,000 other technical books and videos from publishers such as Addison-Wesley Professional, Cisco Press, Exam Cram, IBM Press, O’Reilly, Prentice Hall, and Que.

**SAFARI BOOKS ONLINE** allows you to search for a specific answer, cut and paste code, download chapters, and stay current with emerging technologies.

**Activate your FREE Online Edition at**

[www.informit.com/safarifree](http://www.informit.com/safarifree)

**STEP 1:** Enter the coupon code: QKLYZAA.

**STEP 2:** New Safari users, complete the brief registration form. Safari subscribers, just log in.

If you have difficulty registering on Safari or accessing the online edition, please e-mail customer-service@safaribooksonline.com
