Web applications are hot. Sure, GUI applications might use exotic Swing widgets, but how many GUI apps do you know that are used by millions of users world-wide? As a web app developer, you can free yourself from the grip of deployment problems all standalone apps have, and deliver your app to anyone with a browser. But to build a truly powerful web app, you need Java. You need servlets. You need JSPs. Because plain old static HTML pages are so, well, 1999. Today’s users expect sites that are dynamic, interactive, and custom-tailored. Within these pages you’ll learn to move from web site to web app.
Chapter 1. Why use Servlets & JSPs?

official Sun exam objectives

OBJECTIVES

Servlets & JSP overview

1.1 For each of the HTTP Methods (such as GET, POST, HEAD, and so on):

* Describe benefits of the HTTP Method
* Describe functionality of the HTTP Method
* List triggers that might cause a Client (usually a Web browser) to use the method

Also part of Objective 1.1, but not covered in this chapter:

* Identify the HttpServlet method that corresponds to the HTTP Method

Coverage Notes:

The objectives in this section are covered completely in another chapter, so think of this chapter as a first look foundation for what comes later. In other words, don’t worry about finishing this chapter knowing (and remembering) anything specific from these objectives; just use it for background. If you already know these topics, you can just skim this chapter and jump to chapter 2.

You won’t have any mock exam questions on these topics until you get to the more specific chapter where those topics are covered.
Everybody wants a web site

You have a killer idea for a web site. To destroy the competition, you need a flexible, scalable architecture. You need servlets and JSPs.

Before we start building, let's take a look at the World Wide Web from about 40k feet. What we care most about in this chapter are how web clients and web servers talk to one another.

These next several pages are probably all review for you, especially if you're already a web application developer, but it'll give us a chance to expose some of the terminology we use throughout the book.

The web consists of gazillions of clients (using browsers like Mozilla or Safari) and servers (using web server apps like Apache) connected through wires and wireless networks. Our goal is to build a web application that clients around the globe can access. And to become obscenely rich.

You are here → 3
What does your web server do?

A web server takes a client request and gives something back to the client.

A web browser lets a user request a resource. The web server gets the request, finds the resource, and returns something to the user. Sometimes that resource is an HTML page. Sometimes it's a picture. Or a sound file. Or even a PDF document. Doesn’t matter—the client asks for the thing (resource) and the server sends it back.

Unless the thing isn’t there. Or at least it’s not where the server is expecting it to be. You’re of course quite familiar with the “404 Not Found” error—the response you get when the server can’t find what it thinks you asked for.

When we say “server”, we mean either the physical machine (hardware) or the web server application (software). Throughout the book, if the difference between server hardware and software matters, we’ll explicitly say which one (hardware or software) we’re talking about.

The client’s request contains the name and address (the URL) of the thing the client is looking for.

The server usually has lots of “content” that it can send to clients. That content can be web pages, JPEGs, and other resources.

The server's response contains the actual document that the client requested (or an error code if the request could not be processed).
What does a web client do?

A web client lets the user request something on the server, and shows the user the result of the request.

When we talk about clients, though, we usually mean both (or either) the human user and the browser application.

The browser is the piece of software (like Netscape or Mozilla) that knows how to communicate with the server. The browser’s other big job is interpreting the HTML code and rendering the web page for the user.

So from now on, when we use the term client, we usually won’t care whether we’re talking about the human user or the browser app. In other words, the client is the browser app doing what the user asked it to do.
Chapter 1. Why use Servlets & JSPs?

**HTML and HTTP**

**Clients and servers know HTML and HTTP**

**HTML**

When a server answers a request, the server usually sends some type of content to the browser so that the browser can display it. Servers often send the browser a set of instructions written in HTML, the HyperText Markup Language. The HTML tells the browser how to present the content to the user.

All web browsers know what to do with HTML, although sometimes an older browser might not understand parts of a page that was written using newer versions of HTML.

**HTTP**

Most of the conversations held on the web between clients and servers are held using the HTTP protocol, which allows for simple request and response conversations. The client sends an HTTP request, and the server answers with an HTTP response. Bottom line: if you’re a web server, you speak HTTP.

When a web server sends an HTML page to the client, it sends it using HTTP. (You’ll see the details on how all this works in the next few pages.) (FYI: HTTP stands for HyperText Transport Protocol.)

---

**Chapter 1**
Two-minute HTML guide

When you develop a web page, you use HTML to describe what the page should look like and how it should behave. HTML has dozens of tags and hundreds of tag attributes. The goal of HTML is to take a text document and add tags that tell the browser how to format the text. Below are the tags we use in the next several chapters. If you need a more complete understanding of HTML, we recommend the book *HTML & XHTML: The Definitive Guide*.

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;!--</td>
<td>where you put your comments</td>
</tr>
<tr>
<td>&lt;a&gt;</td>
<td>anchor - usually for putting in a hyperlink</td>
</tr>
<tr>
<td>&lt;align&gt;</td>
<td>align the contents left, right, centered, or justified</td>
</tr>
<tr>
<td>&lt;body&gt;</td>
<td>define the boundaries of the document’s body</td>
</tr>
<tr>
<td>&lt;br&gt;</td>
<td>a line break</td>
</tr>
<tr>
<td>&lt;center&gt;</td>
<td>center the contents</td>
</tr>
<tr>
<td>&lt;form&gt;</td>
<td>define a form (which usually provides input fields)</td>
</tr>
<tr>
<td>&lt;hl&gt;</td>
<td>the first level heading</td>
</tr>
<tr>
<td>&lt;head&gt;</td>
<td>define the boundaries of the document’s header</td>
</tr>
<tr>
<td>&lt;html&gt;</td>
<td>define the boundaries of the HTML document</td>
</tr>
<tr>
<td>&lt;input type&gt;</td>
<td>defines an input widget to a form</td>
</tr>
<tr>
<td>&lt;p&gt;</td>
<td>a new paragraph</td>
</tr>
<tr>
<td>&lt;title&gt;</td>
<td>the HTML document’s title</td>
</tr>
</tbody>
</table>

(Technically, the `center` and `align` tags have been deprecated in HTML 4.0, but we’re using them in some of our examples because it’s simpler to read than the alternative, and you’re not here to learn HTML anyway.)
What you write...
(the HTML)

Imagine you’re creating a login page. The simple HTML.
might look something like this:

```html
<html>
<!-- Some sample HTML -->
<head>
  <title>A Login Page</title>
</head>
<body>
  <h1 align="center">Skyler’s Login Page</h1>
  <p align="right">
    <img src="SKYLER2.jpg" width="130" height="150"/>
  </p>
  <form action="date2">
    Name: <input type="text" name="param1"/>
    Password: <input type="text" name="param2"/>
    <br/>
    <br/>
    <center>
      <input type="SUBMIT"/>
    </center>
  </form>
</body>
</html>
```

_HTML pops up all over the exam. But you’re not being tested on your HTML knowledge. You’ll see HTML in the context of a large chunk of questions, though, so you need at least some idea of what’s happening when you see simple HTML._
What the browser creates...

The browser reads through the HTML code, creates the web page, and renders it to the user's display.

Chapter 1. Why use Servlets & JSPs?

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: O'Reilly Prepared for Stephen Goss, Safari ID: stephengoss@gmx.net

Redistribution or other use that violates the fair use privilege under U.S. copyright laws (see 17 USC107) or that otherwise violates the Safari Terms of Service is strictly prohibited.
HTTP protocol

What is the HTTP protocol?

HTTP runs on top of TCP/IP. If you’re not familiar with those networking protocols, here’s the crash course: TCP is responsible for making sure that a file sent from one network node to another ends up as a complete file at the destination, even though the file is split into chunks when it’s sent. IP is the underlying protocol that moves/routes the chunks (packets) from one host to another on their way to the destination. HTTP, then, is another network protocol that has Web-specific features, but it depends on TCP/IP to get the complete request and response from one place to another. The structure of an HTTP conversation is a simple Request/Response sequence; a browser requests, and a server responds.

![Diagram of HTTP request and response]

You don’t have to memorize the HTTP spec.

The HTTP protocol is an IETF standard, RFC 2616. If you care. (Fortunately, the exam doesn’t expect you to.) Apache is an example of a Web server that processes HTTP requests. Mozilla is an example of a Web browser that provides the user with the means to make HTTP requests and to view the documents returned by the server.
HTML is part of the HTTP response

An HTTP response can contain HTML. HTTP adds header information to the top of whatever content is in the response (in other words, the thing coming back from the server). An HTML browser uses that header info to help process the HTML page. Think of the HTML content as data pasted inside an HTTP response.
**HTTP methods**

**If that’s the response, what’s in the request?**

The first thing you’ll find is an HTTP method name. These aren’t Java methods, but the idea is similar. The method name tells the server the kind of request that’s being made, and how the rest of the message will be formatted. The HTTP protocol has several methods, but the ones you’ll use most often are **GET** and **POST**.

**GET**

User clicks a link to a new page.

Browser sends an HTTP GET to the server, asking the server to GET the page.

User

Browser

Server

**POST**

User types in a form and hits the Submit button.

Browser sends an HTTP POST to the server, giving the server what the user typed into the form.

User

Browser

Server
GET is a simple request, 
POST can send user data

GET is the simplest HTTP method, and its 
main job in life is to ask the server to get a 
resource and send it back. That resource might 
be an HTML page, a JPEG, a PDF, etc. Doesn’t 
matter. The point of GET is to get something 
back from the server.

POST is a more powerful request. It’s like a 
GET plus plus. With POST, you can request 
something and at the same time send form data 
to the server (later in this chapter we’ll see what 
the server might do with that data).

Q: So what about the other HTTP methods 
besides GET and POST?

A: Those are the two big ones that everybody 
uses. But there are a few rarely used methods (and 
Servlets can handle them) including HEAD, TRACE, 
PUT, DELETE, OPTIONS, and CONNECT.

You really don’t need to know much about these 
others for the exam, although you might see 
them appear in a question. The Life and Death 
of a Servlet chapter covers the rest of the HTTP 
method details you’ll need.
HTTP GET

It’s true... you can send a little data with HTTP GET

But you might not want to. Reasons you might use POST instead of GET include:

1. The total amount of characters in a GET is really limited (depending on the server). If the user types, say, a long passage into a “search” input box, the GET might not work.

2. The data you send with the GET is appended to the URL up in the browser bar, so whatever you send is exposed. Better not put a password or some other sensitive data as part of a GET!

3. Because of number two above, the user can’t bookmark a form submission if you use POST instead of GET. Depending on your app, you may or may not want users to be able to bookmark the resulting request from a form submission.

The original URL before the extra parameters.

The "?" separates the path and the parameters (the extra data). The amount of data you can send along with the GET is limited, and it’s exposed up here in the browser bar, and everyone to see. Together, the entire String is the URL that is sent with the request.

And if you need help with the exam, check out javaranch which also includes 100% unbiased recommendations to buy whatever books the authors wrote.
Anatomy of an HTTP GET request

The path to the resource, and any parameters added to the URL are all included on the “request line”.

```
GET /select/selectBeerTaste.jsp?color=dark&taste=malty HTTP/1.1
Host: www.wickedlysmart.com
User-Agent: Mozilla/5.0 (Macintosh; U; PPC Mac OS X Mach–O; en-US; rv:1.4) Gecko/20030624 Netscape/7.1
Accept: text/xml,application/xml,application/xhtml+xml,text/html;q=0.9,text/plain;q=0.8,video/x-mng,image/png,image/jpeg,image/gif;q=0.2,/*;q=0.1
Accept-Language: en-us,en,q=0.5
Accept-Encoding: gzip,deflate
Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7
Keep-Alive: 300
Connection: keep-alive
```

Hey server... GET me the page on this host that's at /select/selectBeerTaste.html and, oh yeah, here are the parameters for you: color = dark & taste = malty. And hurry it up.

Sure, I'll go GET that page and thanks for the parameters. And just FYI, "hurry it up" is not part of the HTTP protocol.
HTTP POST

Anatomy of an HTTP POST request

HTTP POST requests are designed to be used by the browser to make complex requests on the server. For instance, if a user has just completed a long form, the application might want all of the form’s data to be added to a database. The data to be sent back to the server is known as the “message body” or “payload” and can be quite large.

The Request line.

POST /advisor/selectBeerTaste.do HTTP/1.1

Host: www.wickedlysmart.com

User-Agent: Mozilla/5.0 (Macintosh; U; PPC Mac OS X Mach-O; en-US; rv:1.4) Gecko/
20030624 Netscape/7.1

Accept: text/xml,application/xml,application/xhtml+xml,text/html;q=0.9,text/
plain;q=0.8,video/x-mng,image/png,image/gif;q=0.2,*/*;q=0.1

Accept-Language: en-us,en;q=0.5

Accept-Encoding: gzip,deflate

Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7

Keep-Alive: 300

Connection: keep-alive

The message body, sometimes called the “payload.”

color=dark&taste=malty

This time, the parameters are down here in the body, so they aren’t limited the way they are if you use a GET and have to put them in the Request line.

Hey server... please POST this to the resource at /advisor/
selectBeerTaste.do. Don’t forget to look inside the body for the important data I’m sending.

Sure, I’ll find that resource (It’s actually a little application) and when I do, I’ll give it the data in the request body you sent.
Anatomy of an HTTP response, and what the heck is a “MIME type”?

Now that we’ve seen the requests from the browser to the server, let’s look at what the server sends back in response. An HTTP response has both a header and a body. The header info tells the browser about the protocol being used, whether the request was successful, and what kind of content is included in the body. The body contains the contents (for example, HTML) for the browser to display.

The HTTP status code for the response. The protocol version that the web server is using. A text version of the status code.

The content-type response header’s value is known as a MIME type. The MIME type tells the browser what kind of data the browser is about to receive so that the browser will know how to render it. Notice that the MIME type value relates to the values listed in the HTTP request’s “Accept” header (Go look at the Accept header from the previous page’s POST request.)

The body holds the HTML, or other content to be rendered.

Here’s my response to your request. Its type is text/html, but in your request you said that was OK. So unless you were lying to me...
All the pieces. On one page.

The user types a URL.

The HTTP GET is sent to the server.

The server finds the page.

And generates an HTTP response.

The HTTP response is sent to the browser.

Client looks forward to a successful beer transaction.

The browser creates an HTTP GET request.

GET /test/Beer1.html HTTP/1.1
Host: www.wickedlysmart.com
User-Agent: Mozilla/5.0 (Macintosh...)

Beer1.html

<html>
<body>
<form>
    <select>
        <option value="Select">Select a beer type or buy beer</option>
        <option value="1">1</option>
        <option value="2">2</option>
        <option value="3">3</option>
    </select>
</form>
</body>
</html>
GET or POST?
For each description, circle either POST or GET depending on which HTTP method you'd choose for implementing that functionality. If you think it could be either, circle both. But be prepared to defend your answers...

- POST  GET  A user is returning a login name and password.
- POST  GET  A user is requesting a new page via a hyperlink.
- POST  GET  A chat room user is sending a written response.
- POST  GET  A user hits the 'next' button to see the next page.
- POST  GET  A user hits the 'log out' button on a secure banking site.
- POST  GET  A user hits the 'back' button on the browser.
- POST  GET  A user sends a name and address form to the server.
- POST  GET  A user makes a radio button selection.
URL. Whatever you do, don’t pronounce it “Earl.”

When you get to the U’s in the acronym dictionary there’s a traffic jam... URL, URL, URN, where does it end? For now, we’re going to focus on the URLs, or Uniform Resource Locators, that you know and love. Every resource on the web has its own unique address, in the URL format.

**anatomy of a URL**

**URL.** Whatever you do, don’t pronounce it “Earl.”

When you get to the U’s in the acronym dictionary there’s a traffic jam... URL, URL, URN, where does it end? For now, we’re going to focus on the URLs, or Uniform Resource Locators, that you know and love. Every resource on the web has its own unique address, in the URL format.

**Protocol:** Tells the server which communications protocol (in this case HTTP) will be used.

**Server:** The unique name of the physical server you're looking for. This name maps to a unique IP address. IP addresses are numeric and take the form “xxx.yyy.zzz.aaa.” You can specify an IP address here instead of a server name, but a server name is a lot easier to remember.

**Port:** This part of the URL is optional. A single server supports many ports. A server application is identified by a port. If you don’t specify a port in your URL, then port 80 is the default, and as luck would have it, that’s the default port for web servers.

**Path:** The path to the location, on the server, of the resource being requested. Because most of the early servers on the web ran Unix, Unix syntax is still used to describe the directory hierarchies on the web server.

**Resource:** The name of the content being requested. This could be an HTML page, a servlet, an image, PDF, music, video, or anything else the server feels like serving. If this optional part of the URL is left out, most web servers will look for index.html by default.

**Optional Query String:** Remember, if this was a GET request, the extra info (parameters) would be appended to the end of this URL, starting with a question mark “?” and with each parameter (name/value pair) separated by an ampersand “&.”
A TCP port is just a number

A 16-bit number that identifies a specific software program on the server hardware.

Your Internet web (HTTP) server software runs on port 80. That’s a standard. If you’ve got a Telnet server, it’s running on port 23. FTP? 21. POP3 mail server? 110. SMTP? 25. The Time server sits at 37. Think of ports as unique identifiers. A port represents a logical connection to a particular piece of software running on the server hardware. That’s it. You can’t spin your hardware box around and find a TCP port. For one thing, you have 65,536 of them on a server (0 to 65,535). For another, they do not represent a place to plug in physical devices. They’re just numbers representing a server application.

Without port numbers, the server would have no way of knowing which application a client wanted to connect to. And since each application might have its own unique protocol, think of the trouble you’d have without these identifiers. What if your web browser, for example, landed at the POP3 mail server instead of the HTTP server? The mail server won’t know how to parse an HTTP request! And even if it did, the POP3 server doesn’t know anything about serving back an HTML page.

If you’re writing services (server programs) to run on a company network, you should check with the sysadmins to find out which ports are already taken. Your sysadmins might tell you, for example, that you can’t use any port number below 1025, say, 3000.
web site directory

**Directory structure for a simple Apache web site**

We’ll talk more about Apache and Tomcat later, but for now let’s assume that our simple web site is using Apache (the extremely popular, open source web server you’re probably already using). What would the directory structure look like for a web site called www.wickedlysmart.com, hosting two applications, one giving skiing advice, and the other beer-related advice? Imagine that the Apache application is running on port 80.

The .html pages are each marked with a letter (A, B, C, D) for the exercise on the opposite page.

*index.html* is the default page that will be returned to a user who keys “www.wickedlysmart.com” into his browser.

The root folder for the beerAdvice application.

The two applications on this server.

The folders for the beerAdvice app’s two actions.

An HTML page that gives the user some advice.
Mapping URLs to content

Look at the directory structure on the opposite page, then write in a URL that would get you to each of the four .html pages marked with the A, B, C, and D. We did the first one (A) for you, because that’s the kind of people we are. For the exercise, assume Apache is running on port 80. (The answers are at the bottom of the next page.)

A

will cause the server to return to you the index.html page at location

B

will cause the server to return to you the index.html page at location

C

will cause the server to return to you the index.html page at location

D

will cause the server to return to you the selectBeer.html page at location

you are here
Web servers love serving static web pages

A static page just sits there in a directory. The server finds it and hands it back to the client as-is. Every client sees the same thing.

But what if I want, say, the current time to show up on my page? What if I want a page that has something dynamic? Can’t I have something like a variable inside my HTML?

```html
<html>
<body>
  The current time is [insertTimeOnServer].
</body>
</html>
```
But sometimes you need more than just the web server

1. I'm a web server application. I SERVE things. I don't do computation on the things I serve. But I know a real nice program on the same machine that CAN help you out.

2. I can handle that date thing for you.

3. But how does that help? My clients are all web clients. The browser knows only about the web server... so it won't be able to call that other application.

That's not a problem. I'll take care of getting the request to the right helper app, then I'll take that app's response and send it back to the client. In fact, the client never needs to know that someone else did some of the work.
Two things the web server alone won’t do

If you need just-in-time pages (dynamically-created pages that don’t exist before the request), and the ability to write/save data on the server (which means writing to a file or database), you can’t rely on the web server alone.

1 Dynamic content

The web server application serves only static pages, but a separate “helper” application that the web server can communicate with can build non-static, just-in-time pages. A dynamic page could be anything from a catalog to a weblog or even just a page that randomly chooses pictures to display.

When instead of this:

```html
<html>
<body>
The current time is always 4:20 PM on the server
</body>
</html>
```

You want this:

```html
<html>
<body>
The current time is [insertTimeOnServer] on the server
</body>
</html>
```

2 Saving data on the server

When the user submits data in a form, the web server sees the form data and thinks, “So? Like I care?”. To process that form data, either to save it to a file or database or even just to use it to generate the response page, you need another app. When the web server sees a request for a helper app, the web server assumes that parameters are meant for that app. So the web server hands over the parameters, and gives the app a way to generate a response to the client.
The non-Java term for a web server helper app is "CGI" program

Most CGI programs are written as Perl scripts, but many other languages can work including C, Python, and PHP. (CGI stands for Common Gateway Interface, and we don’t care why it’s called that.)

Using CGI, here’s how it might work for a dynamic web page that has the current server date.

1. User clicks a link that has a URL to a CGI program instead of a static page.
2. Web server application ‘sees’ that the request is for a helper program, so the web server launches and runs the program. The web server app sends along any parameters from a GET or POST.
3. The helper app constructs the brand new page (that has the current date inserted) and sends the HTML back to the server. As far as the web server is concerned, the HTML from the helper app is a static page.
4. The helper application is shut down, and the client gets back an HTML page that has the current date as part of its now-static content.
two sides. CGI and Servlets

Servlets and CGI both play the role of a helper app in the web server

CGI is better than Servlets. We write CGI scripts in Perl at our shop, because everybody knows Perl.

I guess that’s fine if you use Java, since you know it. But it’s certainly not worth it for us to switch to Java. There’s no advantage.

You challenge me? On what grounds?

This is no different from Java... what do you call the JVM? Is not every instance of the JVM a heavy-weight process?

I see you have forgotten much. Web servers now are able to keep a single Perl program running between client requests. So the additional overhead argument is worthless.

What are you talking about? Any CORBA-compliant thing can be a J2EE client.

Stop—I’m late for my Pilates class. But this is not over. We’ll have to finish it later.

Listen in as our two black-belts discuss the pros and cons of CGI and Servlets.

I doubt everybody knows Perl. I like Perl, but we’re all Java programmers in our shop so we prefer Java.

With much respect, master, there are many advantages to using Java over Perl for the things you want to do with CGI.

Performance, for one thing. With Perl, the server has to launch a heavy-weight process for each and every request for that resource!

Ah, yes, but you see Servlets stay loaded and client requests for a Servlet resource are handled as separate threads of a single running Servlet. There’s no overhead of starting the JVM, loading the class, and all that...

I have not forgotten, master. But it is not all web servers that can do that. You are talking about a special case which does not apply to all Perl CGI programs. But Servlets will always be more efficient in that way. And let’s not forget that a Servlet can be a J2EE client, while a Perl CGI program cannot.

I do not mean a client to a J2EE program. I mean a client that is J2EE. A Servlet running in a J2EE web container can participate in security and transactions right along with enterprise beans and there are—

to be continued...
Chapter 1. Why use Servlets & JSPs?

```
HTTP/1.1 200 OK
Set-Cookie: ...

<html>
  <body>
    <h1 align="center">Beer Login Page</h1>
    <form>
      Select a beer type or buy beer...
    </form>
  </body>
</html>
```

Client looks forward to a successful beer transaction.

Request Response
Fill in the boxes with a description of what happens during that step in the process. This is a duplicate of page 18, so when you're finished, flip back to that page to compare your answers.

```
GET /Beer1/Beer1.html HTTP/1.1
Host: www.wickedysmart.com
User-Agent: Mozilla/5.0 (Macintosh...
```
quickie look at servlets

Servlets Demystified (write, deploy, run)

Just so those new to servlets can stop holding their breath, here's a quick guide to writing, deploying, and running a servlet. This might create more questions than it answers—don't panic, you don't have to do this right now. It's just a quick demonstration for those who can't wait. The next chapter includes a more thorough tutorial.

1. Build this directory tree (somewhere not under tomcat).

2. Write a servlet named Ch1Servlet.java and put it in the src directory (to keep this example simple, we aren't putting the servlet in a package, but after this, all other servlet examples in the book will be in packages).

```java
import javax.servlet.*;
import java.servlet.http.*;
import java.io.*;

public class Ch1Servlet extends HttpServlet {
    public void doGet(HttpServletRequest request,
     HttpServletResponse response)
     throws IOException {
        PrintWriter out = response.getWriter();
        java.util.Date today = new java.util.Date();
        out.println("<html>" +
        "<body>" +
        "<h1 align=center>HF\'s Chapter1 Servlet</h1>" +
        "<br>" + today + "</body>" + "</html>);
    }
}
```

3. Create a deployment descriptor (DD) named web.xml, put it in the etc directory

```xml
<web-app xmlns="http://java.sun.com/xml/ns/j2ee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
    web-app_2_4.xsd"
    version="2.4">
    <servlet><servlet-name>Chapter1 Servlet</servlet-name>
    <servlet-class>Ch1Servlet</servlet-class>
    </servlet>

    <servlet-mapping>
    <servlet-name>Chapter1 Servlet</servlet-name>
    <url-pattern>/Serv1</url-pattern>
    </servlet-mapping>
</web-app>
```

Highlights:
- One DD per web application.
- A DD can declare many servlets.
- A <servlet-name> ties the <servlet> element to the <servlet-mapping> element.
- A <servlet-class> is the Java class.
- A <url-pattern> is the name the client uses for the request.

HTML imbedded in a Java program. Looks lovely, doesn't it?

SQL imbedded in a Java program. Looks lovely, doesn't it?
Chapter 1. Why use Servlets & JSPs?

4. Build this directory tree under the existing tomcat directory...

5. From the project directory, compile the servlet...

   javac -classpath /your path/tomcat/common/lib/servlet-api.jar -d classes src/Ch1Servlet.java

   (This is all one command.)

   (the Ch1Servlet.class file will end up in project1/classes)

6. Copy the Ch1Servlet.class file to WEB-INF/classes, and copy the web.xml file to WEB-INF.

7. From the tomcat directory, start Tomcat...

   \bin/startup.sh

8. Launch your browser and type in:

   http://localhost:8080/ch1/Serv1

   it should display:

   HF's Chapter1 Servlet

   Tue April 10 16:20:01 MST 2004

9. For now, every time you update either a servlet class or the deployment descriptor, shutdown Tomcat:

   \bin/shutdown.sh

A JSP page looks just like an HTML page, except you can put Java and Java-related things inside the page. So it really is like inserting a variable into your HTML.

```html
<html>
<body>
<h1>Skylar's Login Page</h1>
<br/>
<%= new java.util.Date() %>
</body>
</html>
```
Chapter 1. Why use Servlets & JSPs?

Java meets HTML = JSP

JSP is what happened when somebody introduced Java to HTML

Putting Java into HTML is a solution for two issues:

1. Not all HTML page designers know Java

App developers know Java. Web page designers know HTML. With JSP, Java developers can do Java and HTML developers can do web pages.

2. Formatting HTML into a String literal is REALLY ugly

Putting even marginally complex HTML into the argument to a println() is a compiler error waiting to happen. You might have to do a ton of work to get the HTML formatted properly in a way that still works in the client’s browser, yet satisfies Java rules for what’s allowed in a String literal. You can’t have carriage returns, for example, yet most of the HTML you’ll pull from a web page editor will have real carriage returns in the source. Quotes can be a problem too—a lot of HTML tags use quotes around attribute values, for example. And you know what happens when the compiler sees a double quote... it thinks, “This must be the end of the String literal.” Sure, you can go back and replace each of your double quotes with escape codes... but it all gets insanely error prone.

Q: Wait... there’s still something wrong here! Benefit number one says “Not all page designers know Java...” but the HTML page designer still has to write Java inside the JSP page! JSP lets the Java programmer off the hook for writing HTML, but it doesn’t really help the HTML designer. It might be easier to write HTML in a JSP rather than in a println(), but the HTML developer still has to know Java.

A: Looks that way, doesn’t it? But with the new JSP spec, and by following best practices, the page designer should be putting very little (or no) real Java into a JSP. They do have to learn something... but it’s more like putting in labels that call real Java methods rather than embedding the actual Java code into the page itself. They have to learn JSP syntax, but not the Java language.

34 chapter 1
Chapter 1. Why use Servlets & JSPs?

**Bullet Points**

- HTTP stands for HyperText Transfer Protocol, and is the network protocol used on the Web. It runs on top of TCP/IP.
- HTTP uses a request/response model—the client makes an HTTP request, and the web server gives back an HTTP response that the browser then figures out how to handle (depending on the content type of the response).
- If the response from the server is an HTML page, the HTML is added to the HTTP response.
- An HTTP request includes the request URL (the resource the client is trying to access), the HTTP method (GET, POST, etc.), and (optionally) form parameter data (also called the "query string").
- An HTTP response includes a status code, the content-type (also known as MIME type), and the actual content of the response (HTML, image, etc.)
- A GET request appends form data to the end of the URL.
- A POST request includes form data in the body of the request.
- A MIME type tells the browser what kind of data the browser is about to receive so that the browser will know what to do with it (render the HTML, display the graphic, play the music, etc.)
- URL stands for Uniform Resource Locator. Every resource on the web has its own unique address in this format. It starts with a protocol, followed by the server name, an optional port number, and usually a specific path and resource name. It can also include an optional query string, if the URL is for a GET request.
- Web servers are good at serving static HTML pages, but if you need dynamically-generated data in the page (the current time, for example), you need some kind of helper app that can work with the server. The non-Java term for these helper apps (most often written in Perl) is CGI (which stands for Common Gateway Interface).
- Putting HTML inside a println() statement is ugly and error-prone, but JSPs solve that problem by letting you put Java into an HTML page rather than putting HTML into Java code.
2 high-level overview

Web App Architecture

Behold the power of my Container... a thousand simultaneous hits will not bring me to my knees.

Uh-oh, another victim of J2EE fever.

Servlets need help. When a request comes in, somebody has to instantiate the servlet or at least make a new thread to handle the request. Somebody has to call the servlet’s doPost() or doGet() method. And, oh yes, those methods have crucial arguments—the HTTP request and HTTP response objects. Somebody has to get the request and the response to the servlet. Somebody has to manage the life, death, and resources of the servlet. That somebody is the web Container. In this chapter, we’ll look at how your web application runs in the Container, and we’ll take a first look at the structure of a web app using the Model View Controller (MVC) design pattern.
official Sun exam objectives

Objectives

High-level Web App Architecture

1.1 For each of the HTTP Methods (such as GET, POST, HEAD, and so on), describe the purpose of the method and the technical characteristics of the HTTP Method protocol, list triggers that might cause a client (usually a Web browser) to use the Method, and identify the HttpServletRequest method that corresponds to the HTTP Method.

1.4 Describe the purpose and event sequence of the servlet life cycle: (1) servlet class loading, (2) servlet instantiation, (3) call the init method, (4) call the service method, and (5) call the destroy method.

2.1 Construct the file and directory structure of a Web Application that may contain (a) static content, (b) JSP pages, (c) servlet classes, (d) the deployment descriptor, (e) tag libraries, (f) JAR files, and (g) Java class files; and describe how to protect resource files from HTTP access.

2.2 Describe the purpose and semantics for each of the following deployment descriptor elements: servlet instance, servlet name, servlet class, servlet initialization parameters, and URL to named servlet mapping.

Coverage Notes:

All of the objectives in this section are covered completely in other chapters, so think of this chapter as a first-look foundation for what comes later. In other words, don’t worry about finishing this chapter knowing (and remembering) anything specific from these objectives.

You won’t have any mock exam questions on these topics until you get to the more specific chapter where those topics are covered. Enjoy this nice, simple, background material while you can! BUT... you do need to know this stuff before moving on. If you already have some servlet experience, you can probably just skim the pages, look at the pictures, do the exercises, and move on to chapter 3.
What is a Container?

Servlets don't have a main() method. They're under the control of another Java application called a Container.

Tomcat is an example of a Container. When your web server application (like Apache) gets a request for a servlet (as opposed to, say, a plain old static HTML page), the server hands the request not to the servlet itself, but to the Container in which the servlet is deployed. It's the Container that gives the servlet the HTTP request and response, and it's the Container that calls the servlet's methods (like doPost() or doGet()).
life without servlets

What if you had Java, but no servlets or Containers?

What if you had to write a Java program to handle dynamic requests that come to a web server application (like Apache) but without a Container like Tomcat? In other words, imagine there’s no such thing as servlets, and all you have are the core J2SE libraries! (Of course, you can assume you have the capability of configuring the web server application so that it can invoke your Java application.) It’s OK if you don’t yet know much about what the Container does. Just imagine you need serverside support for a web application, and all you have is plain old Java.

List some of the functions you would have to implement in a J2SE application if no Container existed:

* Create a socket connection with the server, and create a listener for the socket.

...
What does the Container give you?

We know that it’s the Container that manages and runs the servlet, but why? Is it worth the extra overhead?

**Communications support** The container provides an easy way for your servlets to talk to your web server. You don’t have to build a ServerSocket, listen on a port, create streams, etc. The Container knows the protocol between the web server and itself, so that your servlet doesn’t have to worry about an API between, say, the Apache web server and your own web application code. All you have to worry about is your own business logic that goes in your Servlet (like accepting an order from your online store).

**Lifecycle Management** The Container controls the life and death of your servlets. It takes care of loading the classes, instantiating and initializing the servlets, invoking the servlet methods, and making servlet instances eligible for garbage collection. With the Container in control, you don’t have to worry as much about resource management.

**Multithreading Support** The Container automatically creates a new Java thread for every servlet request it receives. When the servlet’s done running the HTTP service method for that client’s request, the thread completes (i.e. dies). This doesn’t mean you’re off the hook for thread safety—you can still run into synchronization issues. But having the server create and manage threads for multiple requests still saves you a lot of work.

**Declarative Security** With a Container, you get to use an XML deployment descriptor to configure (and modify) security without having to hard-code it into your servlet (or any other) class code. Think about that! You can manage and change your security without touching and recompiling your Java source files.

**JSP Support** You already know how cool JSPs are. Well, who do you think takes care of translating that JSP code into real Java? Of course. The Container.

Thanks to the Container, you get to concentrate more on your own business logic instead of worrying about writing code for threading, security, and networking.

You get to focus all your energy on making a fabulous online bubble wrap store, and leave the underlying services like security and JSP processing up to the container.

Now all I have to worry about is how to sell my scratch-n-sniff bubble wrap, instead of having to write all that code for the things the Container’s gonna do for me...

you are here
the Container

How the Container handles a request

We’ll save some of the juicier bits for later in the book, but here’s a quick look:

1. **Client**
   - User clicks a link that has a URL to a servlet instead of a static page.

2. **Web browser**
   - The container “sees” that the request is for a servlet, so the container creates two objects:
     1) HttpServletRequest
     2) HttpServletResponse

3. **Web browser**
   - The container finds the correct servlet based on the URL in the request, creates or allocates a thread for that request, and passes the request and response objects to the servlet thread.
The container calls the servlet’s service() method. Depending on the type of request, the service() method calls either the doGet() or doPost() method.

For this example, we’ll assume the request was an HTTP GET.

The doGet() method generates the dynamic page and stuffs the page into the response object. Remember, the container still has a reference to the response object.

The thread completes, the container converts the response object into an HTTP response, sends it back to the client, then deletes the request and response objects.
**Q:** I remember seeing `doGet()` and `doPost()`, but on the previous page, you show a `service()` method! Where did the `service()` method come from?

**A:** Your servlet inherited it from `HttpServlet`, which inherited it from `GenericServlet` which inherited it from... ahhh, we’ll do class hierarchies to death in the Being A Servlet chapter, so you just need a little more patience.

**Q:** You wimped out on explaining how the container found the correct servlet... like, how does a URL relate to a servlet? Does the user have to type in the exact path and class file name of the servlet?

**A:** No. Good question, though. But it points to a Really Big Topic (servlet mapping and URL patterns), so we’ll take only a quick look on the next few pages, but go into much more detail later in the book (in the Deployment chapter).
You’re wondering how the Container found the Servlet...

Somehow, the URL that comes in as part of the request from the client is mapped to a specific servlet on the server. This mapping of URLs to servlets might be handled in a number of different ways, and it’s one of the most fundamental issues you’ll face as a web app developer. The user request must map to a particular servlet, and it’s up to you to understand and (usually) configure that mapping. What do you think?

**FLEX YOUR MIND**

**How should the Container map servlets to URLs?**

The user does something in the browser (clicks a link, hits the “Submit” button, enters a URL, etc.) and that something is supposed to send the request to a specific servlet (or other web app resource like a JSP) you built. How might that happen?

For each of the following approaches, think about the pros and cons.

1. **Hardcode the mapping into your HTML page.** In other words, the client is using the exact path and file (class) name of the servlet.

   **PROS:**

   **CONS:**

2. **Use your Container vendor’s tool to do the mapping:**

   **PROS:**

   **CONS:**

3. **Use some sort of properties table to store the mappings:**

   **PROS:**

   **CONS:**

   **you are here »** 45
A servlet can have THREE names

A servlet has a **file path name**, obviously, like `classes/registration/SignUpServlet.class` (a path to an actual class file). The original developer of the servlet class chose the **class name** (and the package name that defines part of the directory structure), and the location on the server defines the full path name. But anyone who deploys the servlet can also give it a special **deployment name**. A deployment name is simply a **secret internal** name that doesn’t have to be the same as the class or file name. It can be the same as the servlet **class name** (registration.SignUpServlet) or the relative path to the class **file** (classes/registration/SignUpServlet.class), but it can also be something completely different (like EnrollServlet).

Finally, the servlet has a **public URL name**—the name the client knows about. In other words, the name coded into the HTML so that when the user clicks a link that’s supposed to go to that servlet, this public URL name is sent to the server in the HTTP request.

---

**Client-known URL name**

The client sees a URL for the servlet (in the HTML), but doesn’t really know how that servlet name maps to real directories and files back on the server. The public URL name is a fake name, made up for clients.

**Deployer-known secret internal name**

The deployer can create a name that’s known only to the deployer and others in the real operational environment. This name, too, is a fake name, made up just for the deployment of the servlet. It doesn’t have to match the public URL used by the client. OR the real file and path name of the servlet class.

**Actual file name**

The developer’s servlet class has a fully-qualified name that includes both the class name and the package name. The servlet class file has a real path and file name, depending on where the package directory structure lives on the server.
most aber about it. So you've hard-coded the real path and file name into all the JSPs and other HTML pages that use that servlet. Great. Now what happens when you need to reorganize your application, and possibly move things into different directory structures? Do you really want to force everyone who uses that servlet to know (and forever follow) that same directory structure?

By mapping the name instead of coding in the real file and path name, you have the flexibility to move things around without having the maintenance nightmare of tracking down and changing client code that refers to the old location of the servlet files.

And what about security? Do you really want the client to know exactly how things are structured on your server? Do you want them to, say, attempt to navigate directly to the servlet without going through the right pages or forms? Because if the end-user can see the real path, she can type it into her browser and try to access it directly.

Mapping servlet names improves your app's flexibility and security.
Using the Deployment Descriptor to map URLs to servlets

When you deploy your servlet into your web container, you’ll create a fairly simple XML document called the Deployment Descriptor (DD) to tell the Container how to run your servlets and JSPs. Although you’ll use the DD for more than just mapping names, you’ll use two XML elements to map URLs to servlets—one to map the client-known public URL name to your own internal name, and the other to map your own internal name to a fully-qualified class name.

The two DD elements for URL mapping:

1. `<servlet>`
   maps internal name to fully-qualified class name

2. `<servlet-mapping>`
   maps internal name to public URL name

This web app has two servlets:

- `<servlet>`
  `<servlet-name>`Internal name 1</servlet-name>
  `<servlet-class>`foo.Servlet1</servlet-class>
  `<servlet>`
  `<servlet-name>`Internal name 2</servlet-name>
  `<servlet-class>`foo.Servlet2</servlet-class>

- `<servlet-mapping>`
  `<servlet-name>`Internal name 1</servlet-name>
  `<url-pattern>`/Public1/</url-pattern>
  `<servlet-mapping>`
  `<servlet-name>`Internal name 2</servlet-name>
  `<url-pattern>`/Public2/</url-pattern>

The `<servlet-mapping>` element is used to tie a `<servlet>` element to a specific `<servlet-mapping>` element. The end-user NEVER sees this name; it’s used only in other parts of the DD.

Think of the `<servlet-mapping>` element as what the Container uses at runtime when a request comes in, to ask, “Which servlet should I invoke for this requested URL?”

There is a LOT more that goes into this opening `<web-app>` tag, but we don’t want to show it right now (there’s an example at the end of this chapter).

FKDSWHU
7HENYOUDEPLOYYOURSERVLETINTOYOURWEB#ONTAINER
YOULLCREATEAFAIRLYSIMPLE8-
DOCUMENTCALLEDTHE$EPLOYMENT$ESCRIPTOR$$
TOTELLTHE#ONTAINERHOWTORUNYOUR
SERVLETSAND...
But wait! There’s more you can do with the DD

Besides mapping URLs to actual servlets, you can use the DD to customize other aspects of your web application including security roles, error pages, tag libraries, initial configuration information, and if it’s a full JEE server, you can even declare that you’ll be accessing specific enterprise java beans.

Don’t worry about the details yet. The crucial point for now is that the DD gives you a way to declaratively modify your application without changing source code!

Think about this... it means that even those who aren’t Java programmers can customize your Java web application without having to drag you back from your tropical vacation.

**there are some Dumb Questions**

**Q:** I’m confused. Looking at the DD, you still don’t have anything that indicates the actual path name of the servlet! It just says the class name. This still doesn’t answer the question of how the Container uses that class name to find a specific servlet class file. Is there yet ANOTHER mapping somewhere that says that such and such a class name maps to such and such a file in such and such a location?

**A:** You noticed. You’re right that we put only the class name (fully-qualified to include the package name) into the `<servlet-class>` element. That’s because the Container has a specific place it will look for all servlets for which you’ve specified a mapping in the DD.

In fact, the Container uses a sophisticated set of rules for finding a match between the URL that comes in from the client request and an actual Java class sitting somewhere on the server. But we’ll get into that in a later chapter (on Deployment). Right now, the key point to remember is that you can do this mapping.

**DD Benefits**

- Minimizes touching source code that has already been tested.
- Lets you fine tune your app’s capabilities, even if you don’t have the source code.
- Lets you adapt your application to different resources (like databases), without having to recompile and test any code.
- Makes it easier for you to maintain dynamic security info like access control lists and security roles.
- Lets non-programmers modify and deploy your web applications while you can focus on the more interesting things. Like how appropriate your wardrobe isn’t for a trip to Hawaii.
Bob’s matchmaking site

Story: Bob Builds a Matchmaking Site

Dating is tough today. Who has the time when there’s always another disk to defrag? Bob, who wants a piece of the dot com action (what’s left of it, anyway), believes that creating a geek-specific dating site is his ticket out of the Dilbertian job he has now.

The problem is, Bob’s been a software manager for so long that he’s, um, a little out of touch with contemporary software engineering practices. But he knows some buzzwords and some Java and he’s read a little about servlets, so he makes a quick design and starts to code...
He starts to build a bunch of servlets... one for each page

He considered having just a single servlet, with a bunch of if/then tests, but decided that separate servlets would be more OO—each servlet should have one responsibility like the query page, the sign-up page, the search results page, etc.

Each servlet will have all the business logic it needs to modify or read the database, and prints the HTML to the response stream back to the client.

```java
// import statements
public class DatingServlet extends HttpServlet {
    public void doGet(HttpServletRequest request,
                     HttpServletResponse response)
        throws IOException {
        // business logic goes here, depending
        // on what this servlet is supposed to do
        // (write to the database, do the query, etc.)
        PrintWriter out = response.getWriter();
        // compose the dynamic HTML page
        out.println("something really ugly goes here");
    }
}
```

The servlet does whatever it needs to do to process the request (like insert or search the database) and returns the HTML page in the HTTP response. All of the business logic AND the client HTML page response is inside the servlet code.
Bob adds JSPs

But then it gets ugly, so he adds JSPs

Those pesky println() statements for the output response get really ugly, really quickly. So he reads up on JSPs and decides to have each servlet do whatever business logic it needs to do (query the database, insert or update a new record, etc.) then forward the request to a JSP to do the HTML for the response. This also separates the business logic from the presentation... and since he’s been reading up on design, he knows that separation of concerns is a Good Thing.

// import statements

public class DatingServlet extends HttpServlet {
  public void doGet(HttpServletRequest request, HttpServletResponse response)
  throws IOException {

    // business logic goes here, depending
    // on what this servlet is supposed to do
    // (write to the database, do the query, etc.)
    // forward the request to a specific JSP page
    // instead of trying to print the HTML
    // to the output stream

  }
}

Client fills out the DQL query form and clicks the “Do it” button. This sends an HTTP POST request for the DoDQLQuery. The web server invokes the servlet, the servlet runs the query on the database, then the request is forwarded to the appropriate JSP. The JSP builds the response HTML and sends it back.
But then his friend says, “You ARE using MVC, right?”

Kim wants to know if the dating service can be accessed from a Swing GUI application. Bob says, “No, I hadn’t thought of that.” So Kim says, “Well, it’s not a problem because I’m sure you used MVC, so we can just whip up a Swing GUI client that can access the business logic classes.”

And Bob says, “Gulp.”

And Kim says, “Don’t tell me... you did not use MVC?”

And Bob says, “Well, I did separate out the presentation from the business logic...”

Kim says, “That’s a start... but let me guess... your business logic is all inside servlets?”

Bob realizes, suddenly, why he went into management.

But he’s determined to do this right, so he asks Kim to give him a quick crash overview of MVC.

**With MVC the business logic is not only separate from the presentation... it doesn’t even know that there **IS** a presentation.**

The essence of MVC is that you separate the business logic from the presentation, but put something between them so that the business logic can stand on its own as a reusable Java class, and doesn’t have to know anything about the view.

Bob was partly there, by separating out the business logic from the presentation, but his business logic still has an intimate connection to the view. In other words, he mixed the business logic into a servlet, and that means he can’t reuse his business logic for some other kind of view (like a Swing GUI or even a wireless app). His business logic is stuck in a servlet when it should be in a standalone Java class he can reuse!
MVC design pattern

The Model-View-Controller (MVC) Design Pattern fixes this

If Bob had understood the MVC design pattern, he would have known that the business logic shouldn’t be stuffed inside a servlet. He would have realized that with the business logic embedded in a servlet, he’d be screwed if he ever needed a different way to access the business logic. Like from a Swing GUI app. We’ll talk a lot more about MVC (and other patterns) later in the book, but you need a quick understanding now because the tutorial app we build at the end of this chapter uses MVC.

If you’re already familiar with it, then you know that MVC is not specific to servlets and JSPs—the clean separation of business logic and presentation is just as valid in any other kind of application. But with web apps, it’s really important, because you should never assume that your business logic will be accessed only from the web! We’re sure you’ve worked in this business long enough to know the only guarantee in software development: the spec always changes.

MVC in the Servlet & JSP world

**Controller**
- Takes user input from the request and figures out what it means to the model.
- Tells the model to update itself, and makes the new model state available for the view (the JSP).

**Model**
- Holds the real business logic and the state. In other words, it knows the rules for getting and updating the state.
- A Shopping Cart’s contents (and the rules for what to do with it) would be part of the Model in MVC.
- It’s the only part of the system that talks to the database (although it probably uses another object for the actual DB communication, but we’ll save that pattern for later...)

**View**
- Responsible for the presentation. It gets the state of the model from the Controller (although not directly; the Controller puts the model data in a place where the View can find it). It’s also the part that gets the user input that goes back to the Controller.
Applying the MVC pattern to the matchmaking web app

So, Bob knows what he has to do. Separate out the business logic from the servlets, and create a regular Java class for each one... to represent the Model.

Then the original servlet will be the Controller, the new business logic class will be the Model, and the JSP will be the View.
yeah, but is this a good design?

But then his friend Kim takes a look

Kim comes in and says that while it is an MVC design, it’s a dumb one. Sure, the business logic has been pulled out into a Model, and the servlets act as the Controllers working between the Models and Views so that the Models can be brain-dead about the Views. That’s all good. But look at all those little servlets.

What do they even do? Now that the business logic is safely tucked away in the Model, the servlet Controller isn’t doing much except some generic application stuff for this app, and, oh yeah, it does update the Model and then it kicks the View into gear.

But the worst part is that all that generic application logic is duplicated in every single frickin’ servlet! If one thing needs to change, it has to change everywhere. A maintenance train wreck waiting to happen.

“Yeah, I felt a little weird about the duplicate code,” says Bob, “but what else can I do? Surely you don’t mean for me to put everything in a single servlet again? How could that be good?”
Chapter 2. Web App Architecture

**Is there an answer?**

Should Bob go back to just one servlet Controller, to avoid duplicate code? Would that be bad OO, because the servlets really are doing different things? Does Keanu Reeves really know Kung Fu?

---

**FLEX YOUR MIND**

Leave this for you to ponder, we will.

What do you think? Do you know the answer? IS there an answer? Would you agree with Bob, and leave the servlets as they are, or would you put the code into just one servlet Controller? And if you do use just one Controller for everything, how will the Controller know which Model and View to call?

The answer to this question won't come until the very end of the book, so think about this for a few moments, then put it in a mental background thread...

---

 chapter 2 reflection

Sharpen your pencil

Using MVC in a servlet & JSP world, each of these three components (JSP, Java class, Servlet) plays one of the three MVC roles. Circle the "M", the "V", or the "C" depending on which MVC part that component plays. Circle only one letter per component.

Using MVC in a servlet & JSP world, each of these three components (JSP, Java class, Servlet) plays one of the three MVC roles. Circle the "M", the "V", or the "C" depending on which MVC part that component plays. Circle only one letter per component.

- The Container gives your web app communications support, lifecycle management, multithreading support, declarative security, and support for JSPs, so that you can concentrate of your own business logic.

- The Container creates a request and response object that servlets (and other parts of the web app) can use to get information about the request and send information to the client.

- A typical servlet is a class that extends HttpServlet and overrides one or more service methods that correspond to HTTP methods invoked by the browser (doGet(), doPost(), etc.).

- The deployer can map a servlet class to a URL that the client can use to request that servlet. The name may have nothing to do with the actual class file name.

What do the letters MVC represent in the MVC design pattern?

M stands for ________________________

V stands for ________________________

C stands for ________________________

58  chapter 2
### Who's responsible?

Fill in the table below, indicating whether the web server, the web container, or a servlet is most responsible for the task listed. In a few cases more than one answer may be true for a given task. For extra credit, add a brief comment describing the process.

<table>
<thead>
<tr>
<th>Task</th>
<th>Web server</th>
<th>Container</th>
<th>Servlet</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creates the request &amp; response objects</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Calls the service() method</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Starts a new thread to handle requests</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Converts a response object to an HTTP response</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Knows HTTP</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Adds HTML to the response object</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Has a reference to the response objects</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Finds URLs in the DD</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Deletes the request and response objects</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Coordinates making dynamic content</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Manages lifecycles</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Has a name that matches the &lt;servlet-class&gt; element in the DD</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Servlet**

```java
public class extends HttpServlet {
    public void doGet(

        String d1 = Integer.toString(int {Math.random()}*6+1);  
        String d2 = Integer.toString(int {Math.random()}*6+1);  
        out.println("<html> <body> +  
            "<h1 align=center>HF's Chap 2 Dice Roller</h1> +  
            "<p> d1 + " and " + d2 + " were rolled" +  
            "</body> </html>");
    }
}
```

**DD**

```xml<br/>
<web-app ...>
    <servlet>
        <servlet-name>C2dice</servlet-name>
    </servlet>
</web-app>
```

**Code Magnets**

A working servlet and its DD are scrambled up on the fridge. Can you add the code snippets on the right to the incomplete listings on the left to make a working servlet and DD whose URL ends with /Dice? There might be some extra magnets on the right that you won't use at all!
Code Magnets, continued...

```java
import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;

public void service(C2Dice request, PrintWriter response)

Ch2Dice

PrintWriter out = response.getWriter();
HttpServletRequest request;
HttpServletResponse response;

C2dice

PrintWriter out = response.getWriter();

</url-pattern>
</url-class>
</url-name>

high-level architecture

Servlet

import java.servlet.
import java.servlet.http.
import java.io.

public class Ch2Dice extends HttpServlet

public void doGet(
HttpServletRequest request,
HttpServletResponse response)

throws IOException {

PrintWriter out = response.getWriter();

String d1 = Integer.toString((int)(Math.random()*6)+1); 
String d2 = Integer.toString((int)(Math.random()*6)+1); 
out.println("<html> <body> " +
"<h1 align=center>HF’a Chap 2 Dice Roller</h1>" +
"<p>" + d1 + " and " + d2 + " were rolled" +
"</body> </html>");
}

DD

<web-app ...>

<servlet>

<servlet-name> Ch2Dice </servlet-name>

/servlet</servlet>

</web-app>
two objects, two heaps

A “working” Deployment Descriptor (DD)

Don’t worry about what any of this really means (you’ll see and be tested on this in other chapters). Here, we just wanted to show you a web.xml DD that actually works. The other examples in this chapter were missing a lot of the pieces that go into the opening <web-app> tag. (You can see why we don’t usually include it in our examples.)

The way we usually show it in the book

```xml
<web-app>
  <servlet>
    <servlet-name>Ch3_Beer</servlet-name>
    <servlet-class>com.example.web.BeerSelect</servlet-class>
  </servlet>

  <servlet-mapping>
    <servlet-name>Ch3_Beer</servlet-name>
    <url-pattern>/SelectBeer.do</url-pattern>
  </servlet-mapping>
</web-app>
```

The way it REALLY works

```xml
<web-app xmlns="http://java.sun.com/xml/ns/j2ee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd"
  version="2.4">

  <servlet>
    <servlet-name>Ch3_Beer</servlet-name>
    <servlet-class>com.example.web.BeerSelect</servlet-class>
  </servlet>

  <servlet-mapping>
    <servlet-name>Ch3_Beer</servlet-name>
    <url-pattern>/SelectBeer.do</url-pattern>
  </servlet-mapping>
</web-app>
```
How J2EE fits into all this

The Java 2 Enterprise Edition is kind of a super-s spec—it incorporates other specifications, including the Servlets 2.4 spec and the JSP 2.0 spec. That’s for the web Container. But the J2EE 1.4 spec also includes the Enterprise JavaBean 2.1 specification, for the EJB Container. In other words, the web Container is for web components (Servlets and JSPs), and the EJB Container is for business components.

A fully-compliant J2EE application server must have both a web Container and an EJB Container (plus other things including a JNDI and JMS implementation). Tomcat is just a web Container! It is still compliant with the portions of the J2EE spec that address the web Container.

Tomcat is a web Container, not a full J2EE application server, because Tomcat does not have an EJB Container.

A J2EE application server includes both a web Container AND an EJB Container.

Tomcat is a web Container, but NOT a full J2EE application server.

A J2EE 1.4 server includes the Servlet spec 2.4, JSP spec 2.0, and EJB spec 2.1.

Q: So Tomcat is a standalone web Container... does that mean there are standalone EJB Containers?

A: In the old days, say, the year 2000, you could find complete J2EE application servers, standalone web Containers, and standalone EJB Containers. But today, virtually all EJB Containers are part of full J2EE servers, although there are still a few standalone web Containers, including Tomcat and Resin. Standalone web Containers are usually configured to work with an HTTP web server (like Apache), although the Tomcat Container does have the ability to act as a basic HTTP server. But for HTTP server capability, Tomcat is not nearly as robust as Apache, so the most common non-EJB web apps usually use Apache and Tomcat configured together—with Apache as the HTTP web Server, and Tomcat as the web Container.

Some of the most common J2EE servers are BEA’s WebLogic, the open source JBoss AS, and IBM’s WebSphere.
3 hands-on MVC

Mini MVC Tutorial

Create and deploy an MVC web app. It's time to get your hands dirty writing an HTML form, a servlet controller, a model (plain old Java class), an XML deployment descriptor, and a JSP view. Time to build it, deploy it, and test it. But first, you need to set up your development environment—a project directory structure that's separate from your actual deployed app. Next, you need to set up your deployment environment following the servlet and JSP specs and Tomcat requirements. Then you're ready to start writing, compiling, deploying, and running. True, this is a very small app we're building. But there's almost NO app that's too small to use MVC. Because today's small app is tomorrow's dot com success...
**Objectives**

### Web Application Deployment

2.1 Construct the file and directory structure of a web application that may contain (a) static content, (b) JSP pages, (c) servlet classes, (d) the deployment descriptor, (e) tag libraries, (f) JAR files, and (g) Java class files. Describe how to protect resource files from HTTP access.

2.2 Describe the purpose and semantics for each of the following deployment descriptor elements: error-page, init-param, mime-mapping, servlet, servlet-class, servlet-mapping, servlet-name, and welcome-file.

2.3 Construct the correct structure for each of the following deployment descriptor elements: error-page, init-param, mime-mapping, servlet, servlet-class, servlet-name, and welcome-file.

### Coverage Notes:

All of the objectives in this section are covered completely in the Deployment chapter; this is just a first look. This chapter is the only complete start-to-finish tutorial in the book, so if you skip it, you might have trouble later testing some of the other examples in later chapters (where we don’t go through every detail again). As with the previous two chapters, you don’t need to focus on memorizing the content in this chapter just get in there and do it.
Let’s build a real (small) web application

We looked at the role of a container, we talked a bit about deployment descriptors, and we took a first look at the Model 2 MVC architecture. But you can’t just sit here and read all day—now it’s time to actually do something.

The four steps we’ll follow:

1. **Review the user’s views** (what the browser will display), and the high level **architecture**.

2. Create the **development environment** that we will use for this project (which you can use for any other example in the book).

3. Create the **deployment environment** that we will use for this project (which you can use for any other example in the book).

4. Perform **iterative development and testing** on the various components of our web application. (OK, this is more of a strategy than a step.)

   Note: We recommend iterative development and testing, although we won’t always show all the steps in this book.
user views

The User’s View of the web application—
a Beer Advisor

Our web application is a Beer Advisor. Users will be able to surf to our app, answer a question, and get back stunningly useful beer advice.

Q: Why are we writing a web application that gives beer advice?

A: After an exhaustive marketing research effort, we concluded that 90% of our readers appreciate beer. The other 10% can simply substitute the word “coffee” for “beer.”
Here's the architecture...

Even though this is a tiny application, we'll build it using a simple MVC architecture. That way, when it becomes THE hottest site on the web, we'll be ready to extend the application.

1 - The client makes a request for the form.html page.
2 - The Container retrieves the form.html page.
3 - The Container returns the page to the browser, where the user answers the questions on the form and...

Just a POJO (Plain Old Java Object).

4 - The browser sends the request data to the container.
5 - The Container finds the correct servlet based on the URL, and passes the request to the servlet.
6 - The servlet calls the BeerExpert for help.
7 - The expert class returns an answer, which the servlet adds to the request object.
8 - The servlet forwards the request to the JSP.
9 - The JSP gets the answer from the request object.
10 - The JSP generates a page for the Container.
11 - The container returns the page to the happy user.
Creating your development environment

There are lots of ways you could organize your development directory structure, but here’s what we recommend for small- and medium-sized projects. When it’s time to deploy the web app, we’ll copy a portion of this into wherever our particular Container wants the pieces to go. (In this tutorial, we’re using Tomcat 5.)

We’re of course using a standard package structure so that we get all the normal benefits of packages:
- project organization
- namespace management
- portability and reusability

Notice that we’re separating the controller components from the model components.
Creating the deployment environment

Deploying a web app involves both Container-specific rules and requirements of the Servlets and JSP specifications. (If you’re not deploying to Tomcat, you’ll have to figure out exactly where your web app should be relative to your Container.) In our example, everything below the “Beerv1” directory is the same regardless of your Container!

---

**Tomcat-specific**

This directory name also represents the “context root” which Tomcat uses when resolving URLs. We’ll explore this concept in great detail in the deployment chapter.

Everything below this dotted line is the webapp, and will be the same regardless of your Container vendor.

**Part of the Servlets specification**

This package structure is exactly what we used in the development environment. Unless you’re deploying your classes in a JAR (we’ll talk about that later in the book), then you MUST put the package directory structure immediately under WEB-INF/classes.

**Application-specific**

This web.xml file MUST be in WEB-INF

---

This is the Tomcat home directory; it might be named something else like: jakarta-tomcat-5.0.19.
Our roadmap for building the app

When we started this chapter we outlined a four-step process for developing our web app. So far we've:
1. reviewed the user views for our web app
2. looked at the architecture
3. setup the development and deployment environments for creating and deploying the app

Now it's time for step 4, creating the app.

We borrow from several popular development methodologies (a little from extreme programming, iterative development), and mangle them for our own evil purposes...

The five steps we'll follow (in step 4):

- **Build and test the HTML form that the user will first request.**
- **Build and test version 1 of the controller servlet with the HTML form.** This version is invoked via the HTML form and prints the parameter it receives.
- **Build a test class** for the expert / model class, then build and test the expert / model class itself.
- **Upgrade the servlet to version 2.** This version adds the capability of calling the model class to get beer advice.
- **Build the JSP, upgrade the servlet to version 3** (which adds the capability of dispatching to the JSP), and test the whole app.
The HTML for the initial form page

The HTML is simple—it puts up the heading text, the drop-down list from which the user selects a beer color, and the submit button.

```html
<html><body>
<h1 align="center">Beer Selection Page</h1>
<form method="POST" action="SelectBeer.do">
Select beer characteristics:
Color:
<select name="color" size="1">
<option>light</option>
<option>amber</option>
<option>brown</option>
<option>dark</option>
</select>
<br><br>
<center>
<input type="SUBMIT" name="select">
</center>
</form></body></html>
```

**Q:** Why is the form submitting to “SelectBeer.do” when there is NO servlet with that name? In the directory structures we looked at earlier, I didn’t see anything that had the name “SelectBeer.do”. And what’s with the “.do” extension anyway?

**A:** SelectBeer.do is a logical name, not an actual file name. It’s simply the name we want the client to use. In fact the client will NEVER have direct access to the servlet class file, so you won’t, for example, create an HTML page with a link or action that includes a path to a servlet class file.

The trick is, we’ll use the XML Deployment Descriptor (web.xml) to map from what the client requests (“SelectBeer.do”) to an actual servlet class file the Container will use when a request comes in for “SelectBeer.do”. For now, think of the “.do” extension as simply part of the logical name (and not a real file type). Later in the book, you’ll learn about other ways in which you can use extensions (real or made-up/logical) in your servlet mappings.
deploying and testing

Deploying and testing the opening page

To test it, you need to deploy it into the Container (Tomcat) directory structure, start Tomcat, and bring up the page in a browser.

Create the HTML in your development environment
Create this HTML file, call it form.html, and save it in your development environment under the /beer-v1/web/ directory.

Copy the file into the deployment environment
Place a copy of the form.html file into tomcat/webapps/Beer-v1/. (Remember, your tomcat home directory might have a different name).

Start Tomcat
Throughout this book we’re using Tomcat as both the web server and the web Container. In the real world, you probably use a more robust Web Server (like Apache) configured with a Web Container (like Tomcat). But Tomcat makes a perfectly decent Web Server for everything we need to do in this book.
To start Tomcat, cd into the tomcat home directory and run bin/startup.sh.

Test the page
Open the HTML page in your browser and type:

http://localhost:8080/Beer-v1/form.html

You should see something like the screen shot here.
Creating the Deployment Descriptor (DD)

The main job of this DD is to define the mapping between the logical name the client uses for the request ("SelectBeer.do") and the actual servlet class file (com.example.web.BeerSelect).

1. Create the DD in your development environment

Create this XML document, name it web.xml, and save it in your deployment environment under the /beerv1/etc/ directory.

```xml
<web-app xmlns="http://java.sun.com/xml/ns/j2ee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd"
  version="2.4">
  <servlet>
    <servlet-name>Ch3 Beer</servlet-name>
    <servlet-class>com.example.web.BeerSelect</servlet-class>
  </servlet>
  <servlet-mapping>
    <servlet-name>Ch3 Beer</servlet-name>
    <url-pattern>/SelectBeer.do</url-pattern>
  </servlet-mapping>
</web-app>
```

Don't forget to start with a slash.

2. Copy the file into the deployment environment

Place a copy of the web.xml file into tomcat/webapps/Beerv1/WEB-INF/. You MUST place it there or the Container won't find it and nothing will work, and you'll become depressed.
Mapping the logical name to a servlet class file

1. The user fills out the form and hits submit. The browser generates the request URL:
   `/Beer-v1/SelectBeer.do`

   ![](Image)

   The host server root.
   The web app context root.
   The logical resource name.

   POST `/Beer-v1/SelectBeer.do`
   HTTP/1.1
   Host: www.example.com
   Gateway-protocol: 1.1
   Content-Type: application/x-www-form-urlencoded
   Content-Length: 227

   Servlet mapping parameters:
   `<servlet-mapping>`
   `<url-pattern>`
   `<servlet-name>`
   `<servlet-class>`
   `<url-pattern>`

2. The Container searches the DD and finds a `servlet-mapping` with a `url-pattern` that matches `/SelectBeer.do`, where the slash (/) represents the context root of the web app, and `SelectBeer.do` is the logical name of a resource.

3. The Container sees that the `servlet-name` for this `url-pattern` is `Ch3 Beer`. But that isn't the name of an actual servlet class file. "Ch3 Beer" is the name of a servlet, not a servlet class!

   To the Container, a servlet is something named in the DD under a `servlet-name` tag. The name of the servlet is simply the name used in the DD so that other parts of the DD can map to it.

   ```xml
   <servlet>
     <servlet-name>Ch3 Beer</servlet-name>
     <servlet-class>com.example.web.BeerSelect</servlet-class>
   </servlet>
   <servlet-mapping>
     <url-pattern>/SelectBeer.do</url-pattern>
     <servlet-name>Ch3 Beer</servlet-name>
   </servlet-mapping>
   ```
Chapter 3. Mini MVC Tutorial

hands-on MVC

1. The Container looks inside the <servlet> tags for something with the <servlet-name> "Ch3 Beer".

2. The Container uses the <servlet-class> in the <servlet> tag to know which servlet class is responsible for handling this request. If the servlet has not been initialized, the class is loaded and the servlet is initialized.

3. The Container starts a new thread to handle the request, and passes the request to the thread (to the servlet's service() method).

4. The Container sends the response (through the Web Server, of course) back to the client.

---

Chapter 3. Mini MVC Tutorial
Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: O'Reilly
Prepared for Stephen Goss, Safari ID: stephengoss@gmx.net
Print Publication Date: 8/1/2004
User number: 747221 Copyright 2007, Safari Books Online, LLC.
This PDF is exclusively for your use in accordance with the Safari Terms of Service. No part of it may be reproduced or transmitted in any form by any means without the prior written permission for reprints and excerpts from the publisher. Redistribution or other use that violates the fair use privilege under U.S. copyright laws (see 17 USC107) or that otherwise violates the Safari Terms of Service is strictly prohibited.
The first version of the controller servlet

Our plan is to build the servlet in stages, testing the various communication links as we go. In the end, remember, the servlet will accept a parameter from the request, invoke a method on the model, save information in a place the JSP can find, and forward the request to the JSP. But for this first version, our goal is just to make sure that the HTML page can properly invoke the servlet, and that the servlet is receiving the HTML parameter correctly.

Servlet code

```java
package com.example.web;
import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;

public class BeerSelect extends HttpServlet {

    public void doPost(HttpServletRequest request, HttpServletResponse response) throws IOException, ServletException {
        response.setContentType("text/html");
        PrintWriter out = response.getWriter();
        out.println("Beer Selection Advice<br>
        String c = request.getParameter("color");
        out.println("<br>Got beer color " + c);
    }
}
```

Key APIs

- `javax.servlet.Servlet`
- `javax.servlet.http.HttpServlet`
- `javax.servlet.http.HttpServletRequest`
- `javax.servlet.http.HttpServletResponse`
Compiling, deploying, and testing the controller servlet

Ok, we’ve built, deployed, and tested our HTML, and we’ve built and deployed our DD (well, we put the web.xml into the deployment environment, but technically the DD won’t be deployed until we restart Tomcat). Now it’s time to compile the first version of the servlet, deploy it, and test it via the HTML form. Now we’ll restart Tomcat to make sure that it “sees” the web.xml and servlet class.

Compiling the servlet

Compile the servlet with the -d flag to put the class in the development environment:

```
% cd MyProjects/beerV1
% javac -classpath /Users/bert/Applications2/tomcat/common/lib/
    servlet-api.jar:classes:... -d classes src/com/example/web/BeerSelect.java
```

Deploying the servlet

To deploy the servlet, make a copy of the .class file and move it to the /Beer-v1/WEB-INF/classes/com/example/web directory in the deployment structure.

Testing the servlet

1. Restart tomcat!

2. Launch your browser and go to:
   `http://localhost:8080/Beer-v1/form.html`

3. Select a beer color and hit “Submit”

4. If your servlet is working, you should see the servlet’s response in your browser as something like:
   Beer Selection Advice
   Got beer color brown
Building and testing the model class

In MVC, the model tends to be the “back-end” of the application. It’s often the legacy system that’s now being exposed to the web. In most cases it’s just plain old Java code, without knowledge of the fact that it might be called by servlets. The model shouldn’t be tied down to being used by only a single web app, so it should be in its own utility packages.

The specs for the model

- Its package should be com.example.model
- Its directory structure should be /WEB-INF/classes/com/model
- It exposes one method, getBrands(), that takes a preferred beer color (as a String), and returns an ArrayList of recommended beer brands (also as Strings).

Build the test class for the model

Create the test class for the model (yes, before you build the model itself). You’re on your own here; we don’t have one in this tutorial. Remember, the model will still be in the development environment when you first test it—it’s just like any other Java class, and you can test it without Tomcat.

Build and test the model

Models can be extremely complicated. They often involve connections to legacy databases, and calls to complex business logic. Here’s our sophisticated, rule-based expert system for the beer advice:

```java
public class BeerExpert {
    public List<Beer> getBrands(String color) {
        List<Beer> brands = new ArrayList<>();
        if (color.equals("amber")) {
            brands.add("Jack Amber");
            brands.add("Red Moose");
        } else {
            brands.add("Jail Pale Ale");
            brands.add("Gout Stout");
        }
        return brands;
    }
}
```

Notice how we’ve captured complex, expert knowledge of the beer paradigm using advanced conditional expressions.

Don’t forget to change this to use YOUR specific path to the tomcat home.

```bash
$ cd BeerV1
$ java -classpath /Users/bert/Applications2/tomcat/common/lib/
  servlet-api.jar:classes: -d classes src/com/example/model/BeerExpert.java
```

Chapter 3. Mini MVC Tutorial
Enhancing the servlet to call the model, so that we can get REAL advice...

In this version two servlet we’ll enhance the `doPost()` method to call the model for advice (version three will make the advice come from a JSP). The code changes are trivial, but the important part is understanding the redeployment of the enhanced web app. You can try to write the code, recompile, and deploy on your own, or you can turn the page and follow along...

**Sharpen your pencil**

**Enhance the servlet, version two**

Forget about servlets for a minute, let’s just think Java. What are the steps we have to take to accomplish the following?

1. Enhance the `doPost()` method to call the model.
2. Compile the servlet.
3. Deploy and test the updated web app.

```java
public class BeerSelect extends HttpServlet {
    // Your code here
}
```
calling the model from the servlet controller

**Servlet version two code**

Remember, the model is just plain old Java, so we call it like we’d call any other Java method—instanitate the model class and call its method!

```java
package com.example.web;

import com.example.model.*;
import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;
import java.util.*;

public class BeerSelect extends HttpServlet {

    public void doPost(HttpServletRequest request,
                        HttpServletResponse response)  
                        throws IOException, ServletException {

                response.setContentType("text/html");
                PrintWriter out = response.getWriter();
                out.println("<h1>Beer Selection Advice</h1>");
                String color = request.getParameter("color");

                BeerExpert be = new BeerExpert();
                List result = be.getBrands(color);
                Iterator it = result.iterator();
                while(it.hasNext()) {
                    out.println("<br>try: " + it.next());
                }

            }
}
```

In the final (third) version, the advice will be printed from a JSP instead of the servlet.

---

Chapter 3. Mini MVC Tutorial

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: O'Reilly

Key steps for servlet version two

We have two main things to do: **recompile the servlet** and **deploy the model class**.

**Compiling the servlet**

We’ll use the same compiler command that we used when we built the first version of the servlet.

```
% cd beerV1
% javac -classpath /Users/bert/Applications2/tomcat/common/lib/
  servlet-api.jar:classes: -d classes src/com/example/web/BeerSelect.java
```

**Deploying and testing the web app**

Now, in addition to the servlet, we also have to deploy the model. The key steps are:

1. Move a copy of the servlet .class file to:
   `../Beer-v1/WEB-INF/classes/com/example/web/`<br>
   This replaces the version one servlet class file!

2. Move a copy of the model’s .class file to:
   `../Beer-v1/WEB-INF/classes/com/example/model/`

3. **Shutdown and restart tomcat**

4. **Test the app** via form.html, the final browser output should be something like:

   Beer Selection Advice
   try: Jack Amber
   try: Red Moose
the MVC app

Review the partially completed, MVC beer advice web application

What's working so far...

1 - The browser sends the request data to the Container.
2 - The Container finds the correct servlet based on the URL, and passes the request to the servlet.
3 - The servlet calls the BeerExpert for help.
4 - The servlet outputs the response (which prints the advice).
5 - The Container returns the page to the happy user.

What we WANT...

1 - The browser sends the request data to the Container.
2 - The Container finds the correct servlet based on the URL, and passes the request to the servlet.
3 - The servlet calls the BeerExpert for help.
4 - The expert class returns an answer, which the servlet adds to the request object.
5 - The servlet forwards the request to the JSP.
6 - The JSP gets the answer from the request object.
7 - The JSP generates a page for the Container.
8 - The Container returns the page to the happy user.
Create the JSP “view” that gives the advice

Don’t get your hopes up. You’re going to have to wait for a few chapters before we really start talking about JSPs. This JSP isn’t actually a particularly good one, either (because of its scriptlet code, which we’ll talk about later in the book). For now it should be pretty easy to read, and if you want to experiment a little, go for it. Although we could test this JSP now from the browser, we’ll wait until after we modify the servlet (version three) to see if it works.

Here’s the JSP...

```html
<%@ page import="java.util.*" %>

<html>
<body>
<h1 align="center">Beer Recommendations JSP</h1>
<p>
<% List styles = (List)request.getAttribute("styles");
    Iterator it = styles.iterator();
    while (it.hasNext()) {
      out.print("<br>try: " + it.next());
    }
%>
</body>
</html>
```

Deploying the JSP

We don’t compile the JSP (the Container does that at first request). But we do have to:

1 - Name it “result.jsp”.

2 - Save it in the development environment, in: /web/.

3 - Move a copy of it to the deployment environment in /Beer-v1/.
In this step we’re going to modify the servlet to “call” the JSP to produce the output (view). The Container provides a mechanism called “request dispatching” that allows one Container-managed component to call another, and that’s what we’ll use—the servlet will get the info from the model, save it in the request object, then dispatch the request to the JSP.

The important changes we must make to the servlet:

1. Add the model component’s answer to the request object, so that the JSP can access it. (Step 4)
2. Ask the Container to forward the request to “result.jsp”. (Step 5)
Code for servlet version three

Here’s how we modified the servlet to add the model component’s answer to the request object (so the JSP can retrieve it), and how we asked the Container to dispatch to the JSP.

```java
package com.example.web;
import com.example.model.*;
import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;
import java.util.*;

public class BeerSelect extends HttpServlet {
    public void doPost(HttpServletRequest request,
            HttpServletResponse response)
            throws IOException, ServletException {
            // response.setContentType("text/html");
            // remove the old test output
            // PrintWriter out = response.getWriter();
            // out.println("Beer Selection Advice<br>");
            String c = request.getParameter("color");
            // out.println("<br>Got beer color " + c);
            BeerExpert be = new BeerExpert();
            List result = be.getBrands(c);

            request.setAttribute("styles", result);
            RequestDispatcher view =
                request.getRequestDispatcher("result.jsp");
            view.forward(request, response);
    }
}
```

Now that the JSP is going to produce the output, we should remove the test output from the servlet. We commented it out so that you could still see it here.

Add an attribute to the request object for the JSP to use. Notice the JSP is looking for “styles.”

Instantiate a request dispatcher for the JSP.

Use the request dispatcher to ask the Container to crank up the JSP, sending it the request and response.

hands-on MVC

You are here →
compile, deploy, and test

Compile, deploy, and test the final app!

In this chapter we’ve built an entire (albeit tiny) MVC application using HTML, servlets and JSPs. You can add this to your resume.

Compiling the servlet

We’ll use the same compiler command that we used earlier:

```
% cd beerV1
% javac -classpath /Users/bert/Applications2/tomcat/common/lib/
    servlet-api.jar:classes:. -d classes src/com/example/web/BeerSelect.java
```

Deploying and testing the web app

Now it’s time to redeploy the servlet.

1 - Move a copy of the servlet’s .class file to ./Beer-v1 WEB-INF/classes/com/example/web/ (again, this will replace the previous version two class file).

3 - Shutdown and restart tomcat

```
% cd tomcat
% bin/shutdown.sh
% bin/startup.sh
```

4 - Test the app via form.html

```
http://localhost:8080/Beer-v1/form.html
```

Here’s what you should see!

Beer Recommendations JSP

| try: Jack's Pale Ale |
| try: Goat Stout |

90 chapter 3
There is still so much to learn.

The party’s over. You had three whole chapters to cruise along, write a little code, review the whole HTTP request/response thing.

But there’s still 200 mock exam questions waiting for you in this book, and they start with the next chapter. Unless you’re already familiar with servlet development and deployment, you really shouldn’t turn the page until after you actually do the tutorial in this chapter.

Not that we’re trying to pressure you or guilt-trip you or anything...
4 request AND response

Being a Servlet

He used a GET request to update the database. The punishment will be most severe... no "Yoga with Suzy" classes for 90 days.

Servlets live to service clients. A servlet’s job is to take a client’s request and send back a response. The request might be simple: “get me the Welcome page.” Or it might be complex: “Complete my shopping cart check-out.” The request carries crucial data, and your servlet code has to know how to find it and how to use it. The response carries the info the browser needs to render a page (or download bytes), and your servlet code has to know how to send it. Or not... your servlet can decide to pass the request to something else (another page, servlet, or JSP) instead.
The Servlet Technology Model

1.1 For each of the HTTP Methods (such as GET, POST, HEAD, and so on), describe the purpose of the method and the technical characteristics of the HTTP Method protocol, list triggers that might cause a client (usually a Web browser) to use the Method, and identify the HttpServlet method that corresponds to the HTTP Method.

1.2 Using the HttpservletRequest interface, write code to retrieve HTML form parameters from the request, retrieve HTTP request header information, or retrieve cookies from the request.

1.3 Using the HttpServletResponse interface, write code to set an HTTP response header, set the content type of the response, acquire a text stream for the response, acquire a binary stream for the response, redirect an HTTP request to another URL, or add cookies to the response.*

1.4 Describe the purpose and event sequence of the servlet lifecycle: (1) servlet class loading, (2) servlet instantiation, (3) call the init() method, (4) call the service() method, and (5) call the destroy() method.

Coverage Notes:

All of the objectives in this section are covered completely in this chapter, with the exception of the cookies part of objective 1.3. A lot of the content in this chapter was touched on in chapter two, but in chapter two we said, "Don't worry about memorizing it." In this chapter, you DO have to slow down, really study, and memorize the content. No other chapter will cover these objectives in detail, so this is it.

Do the exercises in the chapter, review the material, then take your first mock exam at the end of the chapter. If you don't get at least 80% correct, go back through the chapter to figure out what you missed, BEFORE you move on to chapter five. Some of the mock exam questions that belong with these objectives have been moved into chapters 5 and 6, because the questions requires additional knowledge of some of the topics we don't cover until those chapters. That means there are fewer mock exam questions in this chapter, and more in later chapters, to avoid testing you on topics you haven't covered.

Important note: while the first three chapters covered background information, from this page forward in the book, virtually everything you're going to see is directly related to or explicitly part of the exam.

* We won't say much about the objectives related to cookies until the Sessions chapter.

94 chapter 4
Servlets are controlled by the Container

In chapter two we looked at the Container’s overall role in a servlet’s life—it creates the request and response objects, creates or allocates a new thread for the servlet, and calls the servlet’s service() method, passing the request and response references as arguments. Here’s a quick review...

1. User clicks a link that has a URL to a servlet.

2. The Container “sees” that the request is for a servlet, so the container creates two objects:
   1) HttpServletResponse
   2) HttpServletRequest

3. The Container finds the correct servlet based on the URL in the request, creates or allocates a thread for that request, and calls the servlet’s service() method, passing the request and response objects as arguments.
Servlets and the Container

The story continues...

1. The service() method figures out which servlet method to call based on the HTTP Method (GET, POST, etc.) sent by the client.
   - The client sent an HTTP GET request, so the service() method calls the servlet's doGet() method, passing the request and response objects as arguments.

2. The servlet uses the response object to write out the response to the client. The response goes back through the Container.

3. The service() method completes, so the thread either dies or returns to a Container-managed thread pool. The request and response object references fall out of scope, so these objects are toast (ready for garbage collection).
   - The client gets the response.
But there’s more to a servlet’s life

We stepped into the middle of the servlet’s life, but that still leaves questions: when was the servlet class loaded? When did the servlet’s constructor run? How long does the servlet object live? When should your servlet initialize resources? When should it clean up its resources?

The servlet lifecycle is simple; there’s only one main state—initialized. If the servlet isn’t initialized, then it’s either being initialized (running its constructor or init() method), being destroyed (running its destroy() method), or it simply does not exist.

[Diagram showing the servlet lifecycle: init(), service(), destroy() and relationship to Web Container and Servlet Class.

Your servlet class no-arg constructor runs (you should NOT write a constructor; just use the compiler-supplied default).

Called only ONCE in the servlet’s life, and must complete before Container can call service().

Container calls to give the servlet a chance to clean up before the servlet is killed (i.e., made ready for garbage collection). Like init(), it’s called only once.

Chapter 4. Being a Servlet
GenericServlet is an abstract class that implements most of the basic servlet methods you'll need, including those from the Servlet interface. You will probably NEVER extend this class yourself. Most of your servlet's "servlet behavior" comes from this class.

NOTE: do NOT try to memorize all of these now! Just get a feel for how the API works.

The Servlet interface says that all servlets have these five methods (the three in bold are lifecycle methods).

The Servlet API

Servlet

- service(ServletRequest, ServletResponse)
- init(ServletConfig)
- destroy()
- getServletConfig()
- getServletInfo()

GenericServlet

- service(ServletRequest, ServletResponse)
- init()
- destroy()
- getServletConfig()
- getServletInfo()
- getInitParameter(String)
- getInitParameterNames()
- getServletContext()
- log(String)
- log(String, Throwable)

HttpServlet

- service(HttpServletRequest, HttpServletResponse)
- doGet(HttpServletRequest, HttpServletResponse)
- doPost(HttpServletRequest, HttpServletResponse)
- doHead(HttpServletRequest, HttpServletResponse)
- doOptions(HttpServletRequest, HttpServletResponse)
- doPut(HttpServletRequest, HttpServletResponse)
- doTrace(HttpServletRequest, HttpServletResponse)
- doDelete(HttpServletRequest, HttpServletResponse)
- getLastModified(HttpServletRequest)

MyServlet

- doPost(HttpServletRequest, HttpServletResponse)
- doGetMethod()
Chapter 4. Being a Servlet

The Three Big Lifecycle Moments

1. When it's called
   The Container calls init() on the servlet instance after the servlet instance is created but before the servlet can service any client requests.

2. What it's for
   Gives you a chance to initialize your servlet before handling any client requests.

3. Do you override it?
   Possibly.
   If you have initialization code (like getting a database connection or registering yourself with other objects), then you'll override the init() method in your servlet class.

2. When it's called
   When the first client request comes in, the Container starts a new thread or allocates a thread from the pool, and causes the servlet's service() method to be invoked.

2. What it's for
   This method looks at the request, determines the HTTP method (GET, POST, etc.) and invokes the matching doGet(), doPost(), etc. on the servlet.

2. Do you override it?
   No. Very unlikely.
   You should NOT override the service() method. Your job is to override the doGet() and/or doPost() methods and let the service() implementation from HttpServlet worry about calling the right one.

3. When it's called
   The service() method invokes doGet() or doPost() based on the HTTP method (GET, POST, etc.) from the request.

3. (We're including only doGet() and doPost() here, because those two are probably the only ones you'll ever use.)

3. What it's for
   This is where your code begins! This is the method that's responsible for whatever the heck your web app is supposed to be doing.
   You can call other methods on other objects, of course, but it all starts from here.

3. Do you override it?
   ALWAYS at least ONE of them! (doGet() or doPost())
   Whichever one(s) you override tells the Container what you support. If you don't override doPost(), for example, then you're telling the Container that this servlet does not support HTTP POST requests.
The service() method is always called in its own stack...

Thread A
The Container calls init() on the servlet instance after the servlet instance is created but before the servlet can service any client requests.
If you have initialization code (like getting a database connection or registering yourself with other objects), then you’ll override the init() method in your servlet class. Otherwise, the init() method from GenericServlet runs.

Thread B
When the first client request comes in, the Container starts (or finds) a thread and causes the servlet’s service() method to be invoked.
You normally will NOT override the service() method, so the one from HttpServlet will run. The service() method figures out which HTTP method (GET, POST, etc.) is in the request, and invokes the matching doGet() or doPost() method. The doGet() and doPost() inside HttpServlet don’t do anything, so you have to override one or both. This thread dies (or is put back in a Container-managed pool) when service() completes.

Thread C
When the second (and all other) client requests come in, the Container again creates or finds a another thread and causes the servlet’s service() method to be invoked.
So, the service() -> doGet() method sequence happens each time there’s a client request. At any given time, you’ll have at least as many runnable threads as there are client requests, limited by the resources or policies/configuration of the Container. (You might, for example, have a Container that lets you specify the maximum number of simultaneous threads, and when the number of client requests exceeds that, some clients will just have to wait.)
Each request runs in a separate thread!

You might hear people say things like, “Each instance of the servlet...” but that’s just wrong. There aren’t multiple instances of any servlet class, except in one special case (called SingleThreadModel, which is inherently evil), but we’re not talking about that special case yet.

The Container runs multiple threads to process multiple requests to a single servlet.

And every client request generates a new pair of request and response objects.
**In the beginning: loading and initializing**

The servlet starts life when the Container finds the servlet class file. This virtually always happens when the Container starts up (for example, when you run Tomcat). When the Container starts, it looks for deployed web apps and then starts searching for servlet class files. (In the Deployment chapter, we’ll go into more details of how, why, and where the Container looks for servlets.)

Finding the class is the first step.

Loading the class is the second step, and it happens either on Container startup or first client use. Your Container might give you a choice about class loading, or it might load the class whenever it wants. Regardless of whether your Container gets the servlet ready early or does it just-in-time when the first client needs it, a servlet’s `init` method will not run until the servlet is fully initialized.

*Your servlet is always loaded and initialized BEFORE it can service its first client request.*

**FLEX YOUR MIND**

Why is there an init() method? In other words, why isn’t the constructor enough for initializing a servlet?

What kind of code would you put in the init() method?

Hint: the init() method takes an object reference argument. What do you think the argument to the init() method might be, and how (or why) would you use it?
A servlet moves from does not exist to initialized (which really means ready to service client requests), beginning with a constructor. But the constructor makes only an object, not a servlet. To be a servlet, the object needs to be granted servletness.

When an object becomes a servlet, it gets all the unique privileges that come with being a servlet, like the ability to use its ServletContext reference to get information from the Container.

Why do we care about initialization details?

Because somewhere between the constructor and the init() method, the servlet is in a Schrödinger's* servlet state. You might have servlet initialization code, like getting web app configuration info, or looking up a reference to another part of the application, that will fail if you run it too early in the servlet's life. It's pretty simple though, if you remember to put nothing in the servlet's constructor!

There’s nothing that can’t wait until init().

* If your quantum mechanics is a little rusty— you might want to do a Google search on “Schrödinger's Cat.” (Warning: pet lovers, just don’t go there.) When we refer to a Schrödinger state, we mean something that is neither fully dead or fully alive, but in some really weird place in between.
Chapter 4. Being a Servlet

What does ‘being a servlet’ buy you?

What happens when a servlet goes from this:

- object

...to this?

- official, card-carrying servlet

### ServletConfig and ServletContext

#### A ServletConfig object

- One ServletConfig object per servlet.
- Use it to pass deployment-time information to the servlet (a database or enterprise bean lookup name, for example) that you don’t want to hard-code into the servlet (servlet init parameters).
- Use it to access the ServletContext.
- Parameters are configured in the Deployment Descriptor.

#### A ServletContext

- One ServletContext per web app. (They should have named it AppContext.)
- Use it to access web app parameters (also configured in the Deployment Descriptor).
- Use it as a kind of application bulletin-board, where you can put up messages (called attributes) that other parts of the application can access (way more on this in the next chapter).
- Use it to get server info, including the name and version of the Container, and the version of the API that’s supported.
But a Servlet’s REAL job is to handle requests. That’s when a servlet’s life has meaning.

In the next chapter we’ll look at ServletConfig and ServletContext, but for now, we’re digging into details of the request and response. Because the ServletConfig and ServletContext exist only to support your servlet’s One True Job: to handle client requests! So before we look at how your context and config objects can help you do your job, we have to back up a little and look at the fundamentals of the request and response.

You already know that you’re handed a request and response as arguments to the doGet() or doPost() method, but what powers do those request and response objects give you? What can you do with them and why do you care?
Request and Response: the key to everything, and the arguments to service()*

The HttpServletRequest methods are about HTTP things like cookies, headers, and sessions. HttpServletRequest interface adds the methods that relate to the HTTP protocol... what your servlet uses to communicate with the client/browser.

The HttpServletResponse methods are about HTTP things like errors, cookies, and headers. HttpServletResponse interface adds methods you care about when you're using HTTP—things like errors, cookies, and headers.

*S The request and response objects are also arguments to the other HttpServletRequest methods that you write—doGet(), doPost(), etc.
Q: Who implements the interfaces for HttpServletRequest and HttpServletResponse? Are those classes in the API?

A: The Container, and No. The classes aren’t in the API because they’re left to the vendor to implement. The good news is, you don’t have to worry about it. Just trust that when the service() method is called in your servlet, it’ll be handed references to two perfectly good objects that implement HttpServletRequest and HttpServletResponse. You should never care about the actual implementation class name or type. All you care about is that you’ll get something that has all the functionality from HttpServletRequest and HttpServletResponse.

In other words, all you need to know are the methods you can call on the objects the Container gives you as part of the request! The actual class in which they’re implemented doesn’t matter to you—you’re referring to the request and response objects only by the interface type.

Q: Am I reading this UML correctly? Are those interfaces extending interfaces?

A: Yes. Remember, interfaces can have their own inheritance tree. When one interface extends another interface (which is all they can do—interfaces can’t implement interfaces), it means that whoever implements an interface must implement all the methods defined in both the interface and its superinterfaces. This means, for example, that whoever implements HttpServletRequest must provide implementation methods for the methods declared in the HttpServletRequest interface and the methods in the ServletRequest interface.

Q: I’m still confused about why there’s a GenericServlet and ServletRequest and ServletResponse. If nobody’s doing anything except HTTP servlets… then what’s the point?

A: We didn’t say nobody. Somebody, somewhere, one could imagine, is using the servlet technology model without the HTTP protocol. Just nobody we’ve met personally or read about. Ever.

Still, the flexibility was designed into the servlet model for those who might want to use servlets with, say, SMTP or perhaps a proprietary custom protocol. The only support built into the API, though, is for HTTP, and that’s what virtually everyone is using.
HTTP Methods

The HTTP request Method determines whether `doGet()` or `doPost()` runs

The client’s request, remember, always includes a specific HTTP Method. If the HTTP Method is a GET, the service() method calls `doGet()`. If the HTTP request Method is a POST, the service() method calls `doPost()`. You probably won’t care about any HTTP Methods except GET and POST

You keep showing `doGet()` and `doPost()` like they’re the only ones, but I KNOW there are eight methods in HTTP 1.1.

Yes, there are other HTTP 1.1 Methods besides GET and POST. There’s also HEAD, TRACE, OPTIONS, PUT, DELETE, and CONNECT.

All but one of the eight has a matching `doXXX()` method in the `HttpServlet` class, so besides `doGet()` and `doPost()`, you’ve got `doOptions()`, `doHead()`, `doTrace()`, `doPut()`, and `doDelete()`. There’s no mechanism in the `HttpServlet` API for handling `doConnect()`, so it’s not part of `HttpServlet`.

But while the other HTTP Methods might matter to, say, a web server developer, a servlet developer rarely uses anything but GET and POST.

For most (or probably all) servlet development, you’ll use either `doGet()` (for simple requests) or `doPost()` (to accept and process form data), and you won’t have to think about the others.
Actually, one or more of the other HTTP Methods might make a (brief) appearance on the exam...

If you’re preparing for the exam, you should be able to recognize all of them from a list, and have at least the briefest idea of what they’re used for. But don’t spend much time here!

In the real servlet world, you care about GET and POST.
In the exam world, you care just a tiny bit about the other HTTP Methods as well.

GET      Asks to get the thing (resource / file) at the requested URL.
POST     Asks the server to accept the body info attached to the request, and give it to the thing at the requested URL. It’s like a fat GET... a GET with extra info sent with the request.
HEAD     Asks for only the header part of whatever a GET would return. So it’s just like GET, but with no body in the response. Gives you info about the requested URL without actually getting back the real thing.
TRACE    Asks for a loopback of the request message, so that the client can see what’s being received on the other end, for testing or troubleshooting.
PUT      Says to put the enclosed info (the body) at the requested URL.
DELETE   Says to delete the thing (resource / file) at the requested URL.
OPTIONS  Asks for a list of the HTTP methods to which the thing at the requested URL can respond.
CONNECT  Says to connect for the purposes of tunneling.
GET and POST

**The difference between GET and POST**

*POST has a body.* That’s the key. Both GET and POST can send parameters, but with GET, the parameter data is limited to what you can stuff into the Request line.

**GET** /advisor/selectBeerTaste.do?color=dark&taste=malty HTTP/1.1
Host: www.wickedlysmart.com
User-Agent: Mozilla/5.0 (Macintosh; U; PPC Mac OS X Mach–O; en-US; rv:1.4) Gecko/20030624 Netscape/7.1
Accept: text/xml,application/xml,application/xhtml+xml,text/html; q=0.9,text/plain; q=0.8,video/x-mng,image/png,image/jpeg,image/gif; q=0.2,**/*; q=0.1
Accept-Language: en-us,en;q=0.5
Accept-Encoding: gzip,deflate
Accept-Charset: ISO-8859-1,utf-8;q=0.7,**/*; q=0.7
Keep-Alive: 300
Connection: keep-alive

**POST** /advisor/selectBeerTaste.do HTTP/1.1
Host: www.wickedlysmart.com
User-Agent: Mozilla/5.0 (Macintosh; U; PPC Mac OS X Mach–O; en-US; rv:1.4) Gecko/20030624 Netscape/7.1
Accept: text/xml,application/xml,application/xhtml+xml,text/html; q=0.9,text/plain; q=0.8,video/x-mng,image/png,image/jpeg,image/gif; q=0.2,**/*; q=0.1
Accept-Language: en-us,en;q=0.5
Accept-Encoding: gzip,deflate
Accept-Charset: ISO-8859-1,utf-8;q=0.7,**/*; q=0.7
Keep-Alive: 300
Connection: keep-alive

The message body, sometimes called the “payload”, contains the parameters that were not put in the Request line.
No, it’s not just about the size

We talked about other issues with GET in chapter one, remember? When you use GET, the parameter data shows up in the browser’s input bar, right after actual URL (and separated with a ‘?’). Imagine a scenario in which you would not want the parameters to be visible.

So, security might be another issue.

Still another issue is whether you need or want end-users to be able to bookmark the request page. GET requests can be bookmarked; POST requests cannot. That might be really important if you have, say, a page that lets users specify search criteria. The users might want to come back a week later and try the same search again now that there’s new data on the server.

But besides size, security, and bookmarking, there’s another crucial difference between GET and POST—the way they’re supposed to be used. GET is meant to be used for getting things. Period. Simple retrieval. Sure, you might use the parameters to help figure out what to send back, but the point is—you’re not making any changes on the server! POST is meant to be used for sending data to be processed. This could be as simple as query parameters used to figure out what to send back, just as with a GET, but when you think of POST, think: update. Think: use the data from the POST body to change something on the server.

And that brings up another issue... whether the request is idempotent. If it’s not, you could get into the kind of trouble a little blue pill can’t fix. If you’re not familiar with the way the term “idempotent” is used in the web world, keep reading...
The story of the non-idempotent request

Diane has a need. She’s trying desperately to purchase Head First Knitting from the Wickedly Smart online book shop which, unbeknownst to Diane, is still in beta. Diane’s low on money—she has just enough in her debit account to cover one book. She considered buying directly from Amazon or the O’Reilly.com site, but decided she wanted an autographed copy, available only from the Wickedly Smart site. A choice she would later come to regret...

1. Diane hits the CHECKOUT button. (She submitted her bank account info earlier.)
2. Servlet electronically debits Diane’s bank account.
3. Servlet updates the database (takes the book out of inventory, creates a new shipping order, etc.).
4. Maybe I didn’t click it right; I better hit the CHECKOUT button again.
Our story continues...

5 The Container sends the request to the Checkout servlet for processing.

6 The servlet does not have a problem with Diane buying the same book she bought before.

I guess she really likes this knitting book a lot... she's buying it twice. Cool.

Servlet electronically debits Diane's bank account for the second time.

7 Diane's bank accepts the debit, but charges her a hefty overdraft fee.

We'll let her buy this book, but we'll charge her an extra $25.00 for being overdrawn. Bad, bad Diane!

Eventually Diane navigates to the Check Order Status page and sees that she has TWO orders for the knitting book...

This is not right... I meant to buy only ONE book. What stupid web app developer made THIS? It should have recognized a duplicate transaction...

Hello bank? This wickedly stupid web programmer made a mistake...

you are here > 113
HTTP methods

Sharpen your pencil

Which of the HTTP methods do you think are (or should be) idempotent? (Based on your previous understanding of the word and/or the Diane double-purchase story you just read.) Answers are at the bottom of this page.

- GET
- POST
- PUT
- HEAD

(We left off CONNECT deliberately, since it’s not part of HttpServletResponse.)

FLEX YOUR MIND

What went wrong with Diane’s transaction?

(And it’s not just ONE thing… there are probably several problems the developer must fix.)

What are some of the ways in which a developer could reduce the risk of this?

(Hint: they might not all be programmatic solutions.)
request and response

Being idempotent is GOOD. It means you can do the same thing over and over again, with no unwanted side effects!

Idempotency is nothing to be ashamed of.

Idempotent

Servlet sends back a response with a generated HTML page.

NOT Idempotent

Servlet uses the POST data to update the database.

Servlet sends back a response with a generated HTML page.
idempotent requests

POST is not idempotent

An HTTP GET is just for getting things, and it’s not supposed to change anything on the server. So a GET is, by definition (and according to the HTTP spec) idempotent. It can be executed more than once without any bad side effects.

POST is not idempotent—the data submitted in the body of a POST might be destined for a transaction that can’t be reversed. So you have to be careful with your doPost() functionality!
**What determines whether the browser sends a GET or POST request?**

**GET**

A simple hyperlink always means a GET.

```
<A HREF="http://www.wickedlysmart.com/index.html/">click here</A>
```

**POST**

If you explicitly say `method="POST"`, then, surprisingly, it's a POST.

```
<form method="POST" action="SelectBeer.do">
  <select name="color" size="1">
    <option>light</option>
    <option>amber</option>
    <option>brown</option>
    <option>dark</option>
  </select>
  <input type="submit"/>
</form>
```

When the user clicks the "SUBMIT" button, the parameters are sent in the body of the POST request. In this example, there's just one parameter, named "color", and the value is the option's beer color the user selected (light, amber, brown, or dark).

**What happens if you do NOT say method="POST" in your <form>?**

This time, there's no method="POST" here.

```
<form action="SelectBeer.do">
  Select beer characteristics:
  <select name="color" size="1">
    <option>light</option>
    <option>amber</option>
    <option>brown</option>
    <option>dark</option>
  </select>
  <input type="submit"/>
</form>
```

Now what happens to the parameters when the user clicks "SUBMIT", if the form doesn't have a method="POST"?
**POST is NOT the default!**

If you don’t put `method=”POST”` into your form, the default is an HTTP GET request. That means the browser sends the parameters in the request header, but that’s the least of your problems. Because if the request comes in as a GET, that means you’ll run into big trouble at runtime if you have only a `doPost()` and not a `doGet()` in your servlet!

**If you do this:**

```html
<form action=”SelectBeer.do”>
```

**And then this:**

```java
public class BeerSelect extends HttpServlet {
    public void doPost(HttpServletRequest request, HttpServletResponse response) {
        // code here
    }
    public void doGet(HttpServletRequest request, HttpServletResponse response) {
        // code here
    }
}
```

**You’ll get this:**

```
FAILURE! If your HTML form uses GET instead of POST, then you MUST have doGet() in your servlet class. The default method for forms is GET.
```

**Q:** What if I want to support both `GET` and `POST` from a single servlet?

**A:** Developers who want to support both methods usually put logic in `doPost()`, then delegate to `doGet()` if this request doesn’t need to do post things:

```java
public void doPost(...) throws IOException, ServletException {
    doGet(request, response);
}
```
Sending and using a single parameter

HTML form

```html
<form method="POST" action="SelectBeer.do">
  <select name="color" size="1">
    <option>light</option>
    <option>amber</option>
    <option>dark</option>
  </select>
  <input type="SUBMIT"/>
</form>
```

HTTP POST request

```
POST /advisor/SelectBeer.do HTTP/1.1
Host: www.wickedlysmart.com
User-Agent: Mozilla/5.0 (Macintosh; U; PPC Mac OS X Mach-O; en-US; rv:1.4) Gecko/20030624
Netscape/7.1
Accept: text/html,application/xhtml+xml,text/html;q=0.9,text/plain;q=0.8,video/x-mng,image/png,image/jpeg,image/gif;q=0.2/*;q=0.1
Accept-Language: en-us,en,q=0.5
Accept-Encoding: gzip,deflate
Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7
Keep-Alive: 300
Connection: keep-alive

```

Servlet class

```java
public void doPost(HttpServletRequest request, HttpServletResponse response) throws IOException, ServletException {
    String colorParam = request.getParameter("color");
    // more enlightening code here...
}
```

Remember, the browser generates this request, so you don’t have to worry about creating it, but here’s what it looks like coming over to the server... (In this example, the String colorParam has a value of “dark”)

This matches the name in the form.

you are here → 119
form parameters

Sending and using TWO parameters

HTML form

```html
<form method="POST" action="SelectBeerTaste.do">
  Select beer characteristics>
  <COLOR>
    <select name="color" size="1">
      <option>light</option>
      <option>amber</option>
      <option>brown</option>
      <option>dark</option>
    </select>
  </COLOR>
  <BODY>
    <select name="body" size="1">
      <option>light</option>
      <option>medium</option>
      <option>heavy</option>
    </select>
  </BODY>
  <center>
    <input type="SUBMIT">
  </center>
</form>
```

HTTP POST request

POST /advisor/SelectBeerTaste.do HTTP/1.1
Host: www.wickedlysmart.com
User-Agent: Mozilla/5.0 (Macintosh; U; PPC Mac OS X Mach-O; en-US; rv:1.4) Gecko/20030624
Netscape/7.1
Accept: text/xml,application/xml,application/xhtml+xml,text/html;q=0.9,text/plain;q=0.8,video/x-msvideo;q=0.5,image/png,image/jpeg,image/gif;q=0.2/*;q=0.1
Accept-Language: en-us,en;q=0.5
Accept-Encoding: gzip, deflate
Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7
Keep-Alive: 300
Connection: keep-alive

color=dark&body=heavy

Now the POST request has both parameters, separated by an ampersand.

Servlet class

```java
public void doPost(HttpServletRequest request, HttpServletResponse response)
  throws IOException, ServletException
{
  String colorParam = request.getParameter("color");
  String bodyParam = request.getParameter("body");
  System.out.println("color=");
  // more code here
}
```

Chapter 4. Being a Servlet

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: O'Reilly  
Prepared for Stephen Goss, Safari ID: stephengoss@gmx.net

Print Publication Date: 8/1/2004

Redistribution or other use that violates the fair use privilege under U.S. copyright laws (see 17 USC107) or that otherwise violates the Safari Terms of Service is strictly prohibited.
You can have multiple values for a single parameter! That means you'll need getParameterValues() that returns an array, instead of getParameter() that returns a String.

Some form input types, like a set of checkboxes, can have more than one value. That means a single parameter ("sizes", for example) will have multiple values, depending on how many boxes the user checked off. A form where a user can select multiple beer sizes (to say that he's interested in ALL of those sizes) might look like this:

```html
<form method="POST"
action="selectbeer.do">
Select beer characteristics<p>
Can Sizes: <p>
<input type="checkbox" name="sizes" value="12oz"> 12 oz. <br/>
<input type="checkbox" name="sizes" value="16oz"> 16 oz. <br/>
<input type="checkbox" name="sizes" value="22oz"> 22 oz. <br/>
</center>
<input type="SUBMIT">
</form>
```

In your code, you'll use the getParameterValues() method that returns an array:

```java
String one = request.getParameterValues("sizes") [0];
String [] sizes = request.getParameterValues("sizes");
```

If you want to see everything in the array, just for fun or testing, you can use:

```java
String [] sizes = request.getParameterValues("sizes");
for(int m=0, n < sizes.length ; n++) {
    out.println("<br>sizes: " + sizes[n]);
}
```

(assume that "out" is a PrintWriter you got from the response)
Besides parameters, what else can I get from a Request object?

The ServletRequest and HttpServletRequest interfaces have a ton of methods you can call, but you don’t need to memorize them all. On your own, you really should look at the full API for javax.servlet. ServletRequest and javax.servlet.http.HttpServletRequest, but here we’ll look at only the methods you’re most likely to use in your work (and which might also show up on the exam).

In the real world, you’ll be lucky (or unlucky, depending on your perspective), to use more than 15% of the request API. Don’t worry if you aren’t clear about how or why you’d use each of these; we’ll see more details on some of them (especially cookies) later in the book.

String client = request.getHeader("User-Agent");

Cookie[] cookies = request.getCookies();

HttpSession session = request.getSession();

String theMethod = request.getMethod();

InputStream input = request.getInputStream();
Q: Why would I ever want to get an InputStream from the request?

A: With a GET request, there’s nothing but the request header info. In other words, there’s no body to care about. BUT... with an HTTP POST, there’s body info. Most of the time, all you care about from the body is sucking out the parameter values (for example, "color=dark") using request.getParameter(), but those values might be large. If you want to get at the raw bytes of everything that comes in with the request, you can do it with the getInputStream() method. With the input stream you could, for example, strip out all the header info and process the raw bytes of the payload (the body) of the request, immediately writing it to a file on the server, perhaps.

Q: What’s the difference between getHeader() and getHeader()? Far as I can tell, headers are always Strings! Even the getHeaderValue() method takes a String representing the name of the header, so what’s the int about?

A: Headers have both a name (like "User-Agent" or "Host") and a value (like "Mozilla/5.0 (Macintosh; U; PPC Mac OS X Mach-O; en-US; rv:1.4) Gecko/20030624 Netscape/7.1.1" or "www.wickedlysmart.com"). The values that come back from headers are always in a String form, but for a few headers, the String represents a number. The "Content-Length" header returns the number of bytes that make up the message-body. The "Max-Fowards" HTTP header, for example, returns an integer indicating how many router hops the request is allowed to make. (You might want to use this header if you’re trying to trace a request that you think is getting stuck in a loop somewhere.)

You could get the value of the "Max-Fowards" header by using getHeader():

```java
String forwards = request.getHeader("Max-Fowards");
int forwardNum = Integer.parseInt(forwards);
```

And that works fine. But if you know the value of the header is supposed to represent an int, you can use getHeaderValue() as a convenience method to save the extra step of parsing the String to an int:

```java
int forwardNum = request.getintHeader("Max-Fowards");
```

The getServerPort(), getLocalPort(), and getRemotePort() methods are confusing!

The difference between getLocalPort() and getServerPort() is more subtle—getLocalPort() says, "to which port was the request originally SENT?" while getLocalPort() says, "on which port did the request END UP?" Yes, there’s a difference, because although the requests are sent to a single port (where the server is listening), the server bounces around and finds a different local port for each thread so that the app can handle multiple clients at the same time.
**Review: servlet lifecycle and API**

**BULLET POINTS**

- The Container initializes a servlet by loading the class, invoking the servlet’s no-arg constructor, and calling the servlet’s init() method.
- The init() method (which the developer can override) is called only once in a servlet’s life, and always before the servlet can service any client requests.
- The init() method gives the servlet access to the ServletConfig and ServletContext objects, which the servlet needs to get information about the servlet configuration and the web app.
- The Container ends a servlet’s life by calling its destroy() method.
- Most of a servlet’s life is spent running a service() method for a client request.
- Every request to a servlet runs in a separate thread. There is only one instance of any particular servlet class.
- Your servlet will almost always extend javax.servlet.http. HttpServlet, from which it inherits an implementation of the service() method that takes an HttpServletRequest and an HttpServletResponse.
- HttpServlet extends javax.servlet.GenericServlet—an abstract class that implements most of the basic servlet methods.
- GenericServlet implements the Servlet interface.
- Servlet classes (except those related to JSPs) are in one of two packages: javax.servlet or javax.servlet.http.
- You can override the init() method, and you must override at least one service method (doGet(), doPost(), etc.).
Review: HTTP and HttpServletRequest

**BULLET POINTS**

- The HttpServletRequest's doGet() and doPost() methods take an HttpServletRequest and an HttpServletResponse.
- The service() method determines whether doGet() or doPost() runs based on the HTTP Method (GET, POST, etc.) of the HTTP request.
- POST requests have a body; GET requests do not, although GET requests can have request parameters appended to the request URL (sometimes called "the query string").
- GET requests are inherently (according to the HTTP spec) idempotent. They should be able to run multiple times without causing any side effects on the server. GET requests shouldn't change anything on the server. But you could write a bad, non-idempotent doGet() method.
- POST is inherently not idempotent, so it's up to you to design and code your app in such a way that if the client sends a request twice by mistake, you can handle it.
- If an HTML form does not explicitly say "method=POST", the request is sent as a GET, not a POST. If you do not have a doGet() in your servlet, the request will fail.
- You can get parameters from the request with the getParameter("paramName") method. The return value is always a String.
- If you have multiple parameter values for a given parameter name, use the getParameterValues("paramName") method that returns a String array.
- You can get other things from the request object including headers, cookies, a session, the query string, and an input stream.
the **HttpServletResponse** object

**So that’s the Request...**

now let’s see the **Response**

The response is what goes back to the client. The thing the browser gets, parses, and renders for the user. Typically, you use the response object to get an output stream (usually a Writer) and you use that stream to write the HTML (or some other type of content) that goes back to the client. The response object has other methods besides just the I/O output, though, and we’ll look at some of them in a bit more detail.

Most of the time, you use the Response just to send data back to the client.

You call two methods on the response: `setContentType()` and `getWriter()`.

After that, you’re simply doing I/O to write HTML (or something else) to the stream. But you can also use the response to set other headers, send errors, and add cookies.

These are some of the most commonly-used methods:

`getBufferSize()`

`setContentLength()`

`getOutputStream()`

`getWriter()`

`setContentType()`

`setLength()`

`setWriter()`

// MANY more methods...

Sometimes you’ll use these too...

`addCookie()`

`addHeader()`

`encodeURL()`

`sendError()`

`sendRedirect()`

// MANY more methods...
OK, yes, we should be using JSPs rather than sending HTML back in the response output stream from a servlet. Formatting HTML to stick in an output stream’s println() method hurts.

But that doesn’t mean you’ll never have to work with an output stream from your servlet. Why?

1) Your hosting provider might not support JSPs. There are plenty of older servers and containers out there that support servlets but not JSPs, so you’re stuck with it.

2) You don’t have the option of using JSPs for some other reason, like, you have an incredibly stupid manager who won’t let you use JSPs because in 1998 his brother-in-law told him that JSPs were bad.

3) Who said that HTML was the only thing you could send back in a response? You might send something other than HTML back to the client. Something for which an output stream makes perfect sense.

Turn the page for an example...
Imagine you want to send a JAR to the client...

Let’s say you’ve created a download page where the client can get code from JAR files. Instead of sending back an HTML page, the response contains the bytes representing the JAR. You read the bytes of the JAR file, then write them to the response’s output stream.

1. Diane is desperate to download the JAR of code for the book she’s using to learn servlets and JSPs. She navigates to the book’s website and clicks the “code jar” link, which refers to a servlet named “Code.do”.

   Browser sends an HTTP request to the server with the name of the requested servlet (“Code.do”).

2. The JAR starts downloading onto the client’s machine. Diane is pleased.

   The CodeReturn servlet gets the bytes for the JAR, then gets an output stream from the response, and writes out the bytes representing the JAR.

3. The Container sends the request to the CodeReturn servlet (mapped to the name “Code.do” in the DD) for processing.
Servlet code to download the JAR

```java
// a bunch of imports here
public class CodeReturn extends HttpServlet {
    public void doGet(HttpServletRequest request, HttpServletResponse response)
            throws IOException, ServletException {
        response.setContentType("application/jar");
        ServletContext ctx = getServletContext();
        InputStream is = ctx.getInputStream("/bookCode.jar");
        int read = 0;
        byte[] bytes = new byte[1024];
        OutputStream os = response.getOutputStream();
        while (((read = is.read(bytes)) != -1) {
            os.write(bytes, 0, read);
        }
        os.flush();
        os.close();
    }
}
```

**Q:** Where was the “bookCode.jar” JAR file located? In other words, where does the getResourceAsStream() method LOOK to find the file? How do you deal with the path?

**A:** The getResourceAsStream() requires you to start with a forward slash (“/”), which represents the root of your web app. Since the web app was named JarDownload, then the directory structure looks like the directories in the picture. The JarDownload directory is inside webapps (as a peer directory to all the other web app directories), then inside JarDownload we put the WEB-INF directory, and the code JAR itself. So the file “bookCode.jar” is sitting at the root level of the JarDownload web app. (Don’t worry, we’ll go into deep penetrating details about the deployment directory structure when we get to the deployment chapter.)
content type

Whoa. What’s the deal with content type?

You might be wondering about this line:

    response.setContentType("application/jar");

Or at least you should be. You have to tell the browser what you’re sending back, so the browser can do the right thing: launch a “helper” app like a PDF viewer or video player, render the HTML, save the bytes of the response as a downloaded file, etc. And since you’re wondering, yes when we say content type we mean the same thing as MIME type. Content type is an HTTP header that must be included in the HTTP response.

Gosh, thanks Server. It’s nice of you to tell me what type you’re sending back. I’ll get the Quicktime player ready for the video...

HTTP response

Client/Browser

Here’s my response to your request. Its type is video/quicktime, and in your request you said that was OK. And despite my trust issues, I believed you.

Server/Container

You don’t need to memorize a bunch of content types.

You should know what setContentType() does, and how you use it, but you don’t have to know even the most common content types except text/html. What you need to know about setContentType() is mostly common sense...

Relax

for example, it won’t do you any good to change the content type AFTER you write to the response output stream. Duh. But that does mean that you can’t set a content type, write some stuff, and then change the content type and write something different. But think about it—how would the browser deal with that? It can handle only one type of THING at a time from the response.

To make sure everything works correctly, your best practice (and in some cases a requirement) is to always call setContentType() first, BEFORE you call the method that gives you your output stream (getWriter() or getOutputStream()). That’ll guarantee you won’t run into conflicts between the content type and the output stream.

Common MIME types:

- text/html
- application/pdf
- video/quicktime
- application/java
- image/jpeg
- application/jar
- application/octet-stream
- application/x-zip
Q: Why do you have to set the content type? Can't servers figure it out from the extension of the file?

A: Most servers can, for static content. In Apache, for example, you can set up MIME types by mapping a specific file extension (.txt, .jar, etc.) to a specific content type, and Apache will use that to set the content type in the HTTP header. But we're talking about what happens inside a servlet where there is no file! You're the one who is sending back the response; the Container has no idea what you're sending.

Q: But what about that last example where you read a specific JAR file? Can't the Container see that you're reading a JAR?

A: No. All we did from the servlet was read the bytes of a file that just happened to be a JAR file, and turn around and write those bytes to the output stream. The Container has no idea what we were up to when we read those bytes. For all it knows we're reading from one type of thing and writing something completely different in the response.

Q: How can I find out what the common content types are?

A: Do a Google search. Seriously. New MIME types are being added all the time, but you can easily find lists on the Web. You can also look in your browser preferences for a list of those that have been configured for your browser, and you can check your Web server configuration files as well. Again, you don't have to worry about this for the exam, and it's not likely to cause you much stress in the real world either.

Q: Wait a second... why would you use a servlet to send back that JAR file when you can just have the web server send it back as a resource? In other words, why wouldn't you have the user click a link that goes to the JAR instead of to a servlet? Can't the server be configured to send back the JAR directly without even GOING through a servlet?

A: Yes. Good question. You COULD configure the web server so that the user clicks an HTML link that goes to, say, the JAR file sitting on the server (just like any other static resource including JPEGs and text files), and the server just sends it back in the response.

But... we're assuming that you might have other things that you want to do in that servlet BEFORE sending back the stream. You might, for example, need logic in the servlet that determines which JAR file to send. Or you might be sending back bytes that you're creating right there on-the-fly. Imagine a system where you take input parameters from the user, and then use them to dynamically generate a sound that you send back. Sound that didn't previously exist. In other words, sound that's not sitting on the server as a file somewhere. You just made it up, and now you're sending it back in the response.

So you're right, perhaps our example of just sending back a JAR sitting on the server is a little contrived, but come on... use your imagination here and embellish it with all sorts of things you might add to make it worth being a servlet. Maybe it's something as simple as putting code in your servlet that—along with sending back the JAR—writes some info to a database about this particular user. Or maybe you have to check to see if he's even allowed to download this JAR, based on something you first read from the database.
PrintWriter and OutputStream

You've got two choices for output: characters or bytes

This is just plain old java.io, except the ServletResponse interface gives you only two streams to choose from: ServletOutputStream for bytes, or a PrintWriter for character data.

▶ PrintWriter

Example:

```java
PrintWriter writer = response.getWriter();
writer.println("some text and HTML");
```

Use it for:

Printing text data to a character stream. Although you can still write character data to an OutputStream, this is the stream that's designed to handle character data.

▶ OutputStream

Example

```java
ServletOutputStream out = response.getOutputStream();
out.write(new byte[] {0, 1, 2, 3, 4});
```

Use it for:

Writing anything else!

FYI: The PrintWriter actually "wraps" the ServletOutputStream. In other words, the PrintWriter has a reference to the ServletOutputStream and delegates calls to it. There's just ONE output stream back to the client, but the PrintWriter "decorates" the stream by adding higher-level character-friendly methods.

You MUST memorize these methods

You have to know these for the exam. And it's tricky. Notice that to write to a ServletOutputStream you write(), but to write to a PrintWriter you... println()! It's natural to assume that you write to a writer, but you don't. If you already use java.io, then you've been down this road. But if you haven't, just remember:

- println() to a PrintWriter
- write() to an ServletOutputStream

Make sure you remember that the method names for getting the stream or the writer both drop the first word in the returned type:

```java
ServletOutputStream response.getOutputStream()
PrintWriter response.getWriter()
```

You need to recognize WRONG method names like:

```java
getOutputStream()
getBytes()
getOutputStream()
```

these are NOT real!
You can set response headers, you can add response headers

And you can wonder what the difference is. But
think about it for a second, then do this exercise.

<table>
<thead>
<tr>
<th>Match the method call</th>
<th>Draw a line from the HttpServletResponse method to the method’s behavior.</th>
</tr>
</thead>
<tbody>
<tr>
<td>response.setHeader(&quot;foo&quot;, &quot;bar&quot;);</td>
<td>We did the most obvious one for you.</td>
</tr>
<tr>
<td>response.setHeader(&quot;foo&quot;, &quot;bar&quot;);</td>
<td>Adds a new header and value to the response, or adds</td>
</tr>
<tr>
<td>response.setIntHeader(&quot;foo&quot;, 42);</td>
<td>an additional value to an existing header.</td>
</tr>
<tr>
<td></td>
<td>A convenience method that replaces the value of an existing</td>
</tr>
<tr>
<td></td>
<td>header with this integer value, or adds a new header and</td>
</tr>
<tr>
<td></td>
<td>value to the response.</td>
</tr>
<tr>
<td></td>
<td>If a header with this name is already in the response, the</td>
</tr>
<tr>
<td></td>
<td>value is replaced with this value. Otherwise, adds a new</td>
</tr>
<tr>
<td></td>
<td>header and value to the response.</td>
</tr>
</tbody>
</table>

Pretty obvious when you see them all together.

But for the exam, you should have them memorized so that if
next Tuesday the guy down the hall asks, “What’s that response
method that lets me add a value to an existing header?” you
can, without the slightest pause, say “It’s addHeader, and it
takes two Strings for the name and value.” Just like that.

Both setHeader() and addHeader() will add a header and
value to the response if the header (the first argument to
the method) is not already in the response. The difference
between set and add shows up when the header is there. In
that case:

setAttribute() overwrites the existing value

addAttribute() adds an additional value

When you call setContentType("text/html"), you’re setting a
header just as if you said:

`setHeader("content-type", "text/html");`

So what’s the difference? No difference... assuming you type the
"content-type" header correctly. The setHeader() method won’t
complain if you misspell the header names—it just thinks
you’re adding a new kind of header. But something else will
fail later, because now you haven’t properly set the content
type of the response!
But sometimes you just don’t want to deal with the response yourself...

You can choose to have something else handle the response for your request. You can either redirect the request to a completely different URL, or you can dispatch the request to some other component in your web app (typically a JSP).

Redirect

1. Client types a URL into the browser bar...
2. The request goes to the server/Container.
3. The servlet decides that the request should go to a completely different URL.
4. The servlet calls sendRedirect(String) on the response and that’s it.
5. The browser gets the response, sees the “301” status code, and looks for a “Location” header.
6. The HTTP response has a status code “301” and a “Location” header, with a URL as the value.
Chapter 4. Being a Servlet

request and response

The browser makes a new request using the URL that was the value of the "Location" header in the previous response. The user might notice that the URL in the browser bar changed...

There's nothing unique about the request, even though it happened to be triggered by a redirect.

The server gets the thing at the requested URL. Nothing special here.

How'd I end up here?

The browser renders the new page. The user is surprised.

The HTTP response is just like any other response... except it isn't coming from the location the client typed in.
Servlet redirect makes the browser do the work

A redirect lets the servlet off the hook completely. After deciding that it can’t do the work, the servlet simply calls the `sendRedirect()` method:

```java
if (worksForMe) {
    // handle the request
} else {
    response.sendRedirect("http://www.oreilly.com");
}
```

The URL you want the browser to use for the request. This is what the client will see.

Using relative URLs in `sendRedirect()`

You can use a relative URL as the argument to `sendRedirect()`, instead of specifying the whole “http://www...” thing. Relative URLs come in two flavors: with or without a starting forward slash (“/”).

Imagine the client originally typed in:

```
```

When the request comes into the servlet named “bar.do”, the servlet calls `sendRedirect()` with a relative URL that does NOT start with a forward slash:

```
sendRedirect("foo/stuff.html");
```

The Container builds the full URL (it needs this for the “Location” header it puts in the HTTP response) relative to the original request URL:

```
```

But if the argument to `sendRedirect()` DOES start with a forward slash:

```
sendRedirect("/foo/stuff.html");
```

The Container builds the complete URL relative to the web app itself, instead of relative to the original URL of the request. So the new URL will be:

```
```

The forward slash at the beginning means “relative to the root of this web app” (on this case, the web app is “myApp”).
You can't do a `sendRedirect()` after writing to the response!

That's probably obvious, but it's the LAW so we're just making sure.
If you look up `sendRedirect()` in the API, you'll see that it throws an
`IllegalStateException` if you try to invoke it after the response has already been committed.

By “committed”, they mean that the response has been sent. That just means
the data has been flushed to the stream.
For practical purposes, it means you can't write to the response and then call
`sendRedirect()`!

But some picky professor will tell you that technically, you could write to the stream
without flushing, and then `sendRedirect()` wouldn’t cause an exception. But it would
be a completely stupid thing to do, so we won’t talk about it. (Except that we just did... talk about it...)
In your servlet, for gosh sakes make a decision! Either handle the request or do
a `sendRedirect()` to have someone ELSE handle the request.
(By the way, this idea that “once it’s committed it’s too late” also applies to
setting headers, cookies, status codes, the content-type, and so on...)

Well, it takes a `String`. That is a `URL`. The point is,
`sendRedirect()` does NOT take an object of type `URL`,
and pass in a `String` that's either a complete `URL` or a
relative one. If the Container can't build a relative `URL`
as a full one, it'll throw an `IllegalStateException`,
The tricky part is to remember that THIS is wrong:
`sendRedirect(new URL("http://www.oreilly.com");`:

No! It looks so right, but it's SO wrong.
`sendRedirect()` takes a `String`. Period.

`request` and `response`
**A request dispatch does the work on the server side**

And that’s the big difference between a redirect and a request dispatch—redirect makes the client do the work while request dispatch makes something else on the server do the work. So remember: redirect = client, request dispatch = server.

We’ll say more about request dispatch in a later chapter, but these two pages should give you a quick look at the highlights.

---

**Request Dispatch**

1. User types a servlet’s URL into the browser bar...

2. The request goes to the server/Container.

3. The servlet decides that the request should go to another part of the web app (in this case, a JSP).

4. The browser gets the response in the usual way, and renders it for the user. Since the browser location bar didn’t change, the user does not know that the JSP generated the response.

5. The servlet calls
   ```java
   request.getRequestDispatcher("result.jsp").forward(request, response);
   ```

6. and the JSP takes over the response.
Redirect vs. Request Dispatch

When a servlet does a redirect, it's like asking the client to call someone else instead. In this case, the client is the browser, not the user. The browser makes the new call on the user's behalf, after the originally-requested servlet says, "Sorry, call this guy instead..."

The user sees the new URL in the browser.

Hey Kari, this is Dan... I want your help with a client. I'll forward you the details on how to get back to him, but I need you to take over now.

Yes I KNOW you have needs too... yes I KNOW how important the View is in Model View Controller, yes, I can't hear you like another 10% perk.

See that... what? I can use that view breezing up, sorry.

When a servlet does a request dispatch, it's like asking a co-worker to take over working with a client. The co-worker ends up responding to the client, but the client doesn't care as long as someone responds.

The user never knows someone else took over, because the URL in the browser bar doesn't change.

request and response

you are here ▶ 139
**BULLET POINTS**

- You use the Response to send data back to the client.
- The most common methods you’ll call on the response object (HttpServletResponse) are `setContent()` and `getWriter()`.
- Be careful—many developers assume the method is `getPrintWriter()`, but it’s `getWriter()`.
- The `getWriter()` method lets you do character I/O to write HTML (or something else) to the stream.
- You can also use the response to set headers, send errors, and add cookies.
- In the real world, you’ll probably use a JSP to send most HTML responses, but you may still use a response stream to send binary data (like a JAR file, perhaps) to the client.
- The method you call on your response for getting a binary stream is `getOutputStream()`.
- The `setContent()` method tells the browser how to handle the data coming in with the response. Typical content types are “text/html”, “application/pdf”, and “image/jpeg”.
- You don’t have to memorize content types (also known as MIME types).
- You can set response headers using `addHeader()` or `setHeader()`. The difference depends on whether the header is already part of the response. If it is, `setHeader()` will replace the value, but `addHeader()` will add an additional value to the existing response. If the header is not already part of the response, then `setHeader()` and `addHeader()` behave in exactly the same way.
- If you don’t want to respond to a request, you can redirect the request to a different URL. The browser takes care of sending the new request to the URL you provide.
- To redirect a request, call `sendRedirect(StringURL)` on the response.
- You cannot call `sendRedirect()` after the response is committed! In other words, if you’ve already written something to the stream, it’s too late to do a redirect.
- A request redirect is different from a request dispatch. A request dispatch (covered more in another chapter) happens on the server, while a redirect happens on the client. A request dispatch hands the request to another component on the server, usually within the same web app. A request redirect simply tells the browser to go to a different URL.
Mock Exam Chapter 4

1. How would servlet code from a service method (e.g., `doPost()`) retrieve the value of the "User-Agent" header from the request? (Choose all that apply.)
   - A. `String userAgent = request.getParameter("User-Agent");`
   - B. `String userAgent = request.getHeader("User-Agent");`
   - C. `String userAgent = request.getRequestHeader("Mozilla");`
   - D. `String userAgent = getServletContext().getInitParameter("User-Agent");`

2. Which HTTP methods are used to show the client what the server is receiving? (Choose all that apply.)
   - A. GET
   - B. PUT
   - C. TRACE
   - D. RETURN
   - E. OPTIONS

3. Which method of `HttpServletResponse` is used to redirect an HTTP request to another URL?
   - A. `sendURL()`
   - B. `redirectURL()`
   - C. `redirectHttp()`
   - D. `sendRedirect()`
   - E. `getRequestDispatcher()`
mock exam  

4 Which HTTP methods are NOT considered idempotent? (Choose all that apply.)
- A. GET
- B. POST
- C. HEAD
- D. PUT

5 Given `req` is a `HttpServletRequest`, which gets a binary input stream? (Choose all that apply.)
- A. `BinaryInputStream s = req.getInputStream();`
- B. `ServletInputStream s = req.getInputStream();`
- C. `BinaryInputStream s = req.getBinaryStream();`
- D. `ServletInputStream s = req.getBinaryStream();`

6 How would you set a header named “CONTENT-LENGTH” in the `HttpServletResponse` object? (Choose all that apply.)
- A. `response.setHeader("CONTENT-LENGTH","numBytes");`
- B. `response.setHeader("CONTENT-LENGTH","numBytes");`
- C. `response.setStatus(1024);`
- D. `response.setHeader("CONTENT-LENGTH",1024);`

7 Choose the servlet code fragment that gets a binary stream for writing an image or other binary type to the `HttpServletResponse`.
- A. `java.io.PrintWriter out = response.getWriter();`
- B. `ServletOutputStream out = response.getOutputStream();`
- C. `java.io.PrintWriter out = new PrintWriter(response.getWriter());`
- D. `ServletOutputStream out = response.getBinaryStream();`
Chapter 4. Being a Servlet

request and response

8  Which methods are used by a servlet to handle form data from a client? (Choose all that apply.)
   - A. HttpServletRequest.doGet()
   - B. HttpServletResponse.doPost()
   - C. HttpServletRequest.doForm()
   - D. ServletException.doGet()
   - E. HttpServletRequest.doGet()
   - F. HttpServletRequest.doForm()

9  Which of the following methods are declared in HttpServletRequest as opposed to in ServletRequest? (Choose all that apply.)
   - A. getMethod()
   - B. getHeader()
   - C. getParameterNames()
   - D. getInputStream()
   - E. getParameterNames()

10  How should servlet developers handle the HttpServletResponse.service() method when extending HttpServlet? (Choose all that apply.)
    - A. They should override the service() method in most cases.
    - B. They should call the service() method from doGet() or doPost().
    - C. They should call the service() method from the init() method.
    - D. They should override at least one doXXX() method (such as doPost()).
mock answers

Chapter 4 Answers

1. How would servlet code from a service method (e.g., `doPost()` ) retrieve the value of the "User-Agent" header from the request? (Choose all that apply.)
   - A. `String userAgent = request.getParameter("User-Agent");`
   - B. `String userAgent = request.getHeader("User-Agent");`
   - C. `String userAgent = request.getRequestHeader("Mozilla");`
   - D. `String userAgent = getServletContext().getInitParameter("User-Agent");`
     - Option B shows the correct method call passing in the header name as a String parameter.

2. Which HTTP methods are used to show the client what the server is receiving? (Choose all that apply.)
   - A. GET
   - B. PUT
   - C. TRACE  - This method is typically used for troubleshooting, not for production.
   - D. RETURN
   - E. OPTIONS

3. Which method of `HttpServletResponse` is used to redirect an HTTP request to another URL?
   - A. `sendRedirect()`
   - B. `redirectURL()`
   - C. `redirectHttp()`
   - D. `sendRedirect()`  - Option D is correct, and of the methods listed, it's the only one that exists in `HttpServletResponse`.
   - E. `getRequestDispatcher()`

144 chapter 4
4. Which HTTP methods are NOT considered idempotent? (Choose all that apply.)

- A. GET
- B. POST
- C. HEAD
- D. PUT

5. Given req is a HttpServletRequest, which gets a binary input stream? (Choose all that apply.)

- A. BinaryInputStream s = req.getInputStream();
- B. ServletInputStream s = req.getInputStream();
- C. BinaryInputStream s = req.getBinaryStream();
- D. ServletInputStream s = req.getBinaryStream();

6. How would you set a header named "CONTENT-LENGTH" in the HttpServletRequest object? (Choose all that apply.)

- A. response.setHeader("CONTENT-LENGTH","numBytes");
- B. response.setHeader("CONTENT-LENGTH","numBytes");
- C. response.setStatus(1024);
- D. response.setHeader("CONTENT-LENGTH",1024);

7. Choose the servlet code fragment that gets a binary stream for writing an image or other binary type to the HttpServletResponse.

- A. java.io.PrintWriter out = response.getWriter();
- B. ServletOutputStream out = response.getOutputStream();
- C. java.io.PrintWriter out = new PrintWriter(response.getWriter());
- D. ServletOutputStream out = response.getBinaryStream();
mock answers

8. Which methods are used by a servlet to handle form data from a client? (Choose all that apply.)
- A. HttpServletRequest.doPost()
- C. HttpServletRequest.doForm()
- D. ServletRequest.doGet()
- F. ServletRequest.doForm()

- Options C-F are wrong because these methods don’t exist.

9. Which of the following methods are declared in HttpServletRequest as opposed to in ServletRequest? (Choose all that apply.)
- A. getMethod()
- B. getHeader()
- C. getParameterNames()

- Options A, B, and C all relate to components of an HTTP request.

10. How should servlet developers handle the HttpServletRequest's service() method when extending HttpServlet? (Choose all that apply.)
- A. They should override the service() method in most cases.
- B. They should call the service() method from doGet() or doPost().
- D. They should override at least one doXXX() method (such as doPost()).

- Option D is correct; developers typically focus on the doGet() and doPost() methods.
5 attributes and listeners

Being a Web App

But master... he used a context attribute when he should have used a request attribute. He must be killed.

You must understand how the pieces of the web app interact, and you must respect the threads. If you score well on this chapter's mock exam, I will let you live.

No servlet stands alone. In today's modern web app, many components work together to accomplish a goal. You have models, controllers, and views. You have parameters and attributes. You have helper classes.

But how do you tie the pieces together? How do you let components share information? How do you hide information? How do you make information thread-safe? Your life may depend on the answers, so, be sure you have plenty of tea when you go through this chapter. And not that foaly herbal decaf crap.
Chapter 5. Being a Web App

official Sun exam objectives

OBJECTIVES

The Web Container Model

3.1 For the servlet and ServletContext initialization parameters: write servlet code to access initialization parameters, and create deployment descriptor elements for declaring initialization parameters.

3.2 For the fundamental servlet attribute scopes (request, session, and context): write servlet code to add, retrieve, and remove attributes; given a usage scenario, identify the proper scope for an attribute; and identify multi-threading issues associated with each scope.

3.3 Describe the elements of the Web container request processing model: Filter, Filter chain, Request and response wrappers, and Web resource (servlet or JSP page).

3.4 Describe the Web Container lifecycle event model for requests, sessions, and web applications; create and configure listener classes for each scope life cycle; create and configure scope attribute listener classes; and given a scenario, identify the proper attribute listener to use.

3.5 Describe the RequestDispatcher mechanism; write servlet code to create a request dispatcher; write servlet code to forward or include the target resource; and identify the additional request-scoped attributes provided by the container to the target resource.

Coverage Notes:

All of the objectives in this section are covered completely in this chapter, with the exception of 3.3, which is covered in the Filters chapter.

Most of what's in this chapter will come up in other parts of the book, but if you're taking the exam, THIS is the chapter where we expect you to learn and memorize the objective topics.
attributes and listeners

I want my email address to show up on the bezer web page my servlet makes... but I think my email is gonna change and I don’t want to have to recompile my servlet code just to change it...

Kim wants to configure his email address in the DD not hard-code it inside the servlet class

Here’s what Kim does not want in his servlet:

```java
PrintWriter out = response.getWriter();
out.println("bloop@wickedlysmart.com");
```

Hard-coding the address is BAD!

What happens when his email changes?

He’ll have to recompile...

He'd much rather put his email address in the Deployment Descriptor (web.xml file) so that when he deploys his web app, his servlet can somehow “read” his email address from the DD. That way, he won’t have to hard-code his address in the servlet class, and to change his email he modifies only the web.xml file, without having to touch his servlet source code.
**Init Parameters to the rescue**

You’ve already seen the request parameters that can come over in a doGet() or doPost(), but servlets can have initialization parameters as well.

**In the DD (web.xml) file:**

```xml
<servlet>
    <servlet-name>BeanParamTests</servlet-name>
    <servlet-class>TestInitParam</servlet-class>

    <init-param>
        <param-name>adminEmail</param-name>
        <param-value>ilikewecare@wickedlysmart.com</param-value>
    </init-param>

</servlet>
```

**In the servlet code:**

```java
out.println(getServletConfig().getInitParameter("adminEmail"));
```

Every servlet inherits a getServletConfig() method. The getServletConfig() method returns a ServletConfig. And one of its methods is getInitParameter().

You give it a param-name and a param-value. Simple. Just make sure it’s inside the `<servlet>` element in the DD.
You can't use servlet init parameters until the servlet is initialized

You already saw that your servlet inherits getServletConfig(), so you can call that from any method in your servlet to get a reference to a ServletConfig. Once you have a ServletConfig reference, you can call getInitParameter(). But remember, you can't call it from your constructor! That's too early in the servlet's life... it won't have its full serveliness until the Container calls init().

When the Container initializes a servlet, it makes a unique ServletConfig for the servlet.

The Container "reads" the servlet init parameters from the DD and gives them to the ServletConfig, then passes the ServletConfig to the servlet's init() method.

This is when the servlet gets its ServletConfig object.

By the time the servlet is running service methods (doGet(), doPost(), etc.) it's got a ServletConfig.

Q: Way back in the last chapter, you said it takes two things for the servlet to become a card-carrying, fez-wearing servlet. You mentioned both ServletConfig and something called ServletContext.

A: OK, yes, well look at the ServletContext in just a few pages. For now, we care only about ServletConfig, because that's where you get your servlet init parameters.

Q: Wait a minute! In the last chapter you said that we could override the init() method, and nobody said a word about the ServletConfig argument!

A: We didn't mention that the init() method takes a ServletConfig because the one you override doesn't take one. Your superclass includes two versions of init(), one that takes a ServletConfig and a convenience version that's a no-arg. The inherited init(ServletConfig) method calls the no-arg init() method, so the only one you need to override is the no-arg version.

There's no law that stops you from overriding the one that takes a ServletConfig, but if you do, then you better call super.init(ServletConfig)! But there's really NO reason why you need to override the init(ServletConfig) method, since you can always get your ServletConfig by calling your inherited getServletConfig() method.
**The servlet init parameters are read only ONCE — when the Container initializes the servlet**

When the Container makes a servlet, it reads the DD and creates the name/value pairs for the ServletConfig. The Container never reads the init parameters again! Once the parameters are in the ServletConfig, they won’t be read again until/unless you redeploy the servlet. Think about that.

1. Container reads the Deployment Descriptor for this servlet, including the servlet init parameters (init-param).
2. Container creates a new ServletConfig instance for this servlet.
3. Container creates a name/value pair of Strings for each servlet init parameter. Assume we have only one.
4. Container gives the ServletConfig references to the name/value init parameters.
5. Container creates a new instance of the servlet class.
6. Container calls the servlet’s init() method, passing in the reference to the ServletConfig.
Since the Container reads the servlet init parameters only once, you still can't change your email address during the life of the servlet. So this is a dumb solution.

It's still way better than putting it in my servlet source code. All I have to do is change the xml and hit the " redeploy" button, and the new address will be in the ServletConfig.

Q: So, um, where's that " redeploy" button on Tomcat?

A: With Tomcat, there isn't a one-button, really simple admin tool for deployment and redeployment (although there is an admin tool that ships with Tomcat). But think about it—what the worst you have to do to change the servlet's init parameters? You make a quick change to the web.xml file, shut down Tomcat (bin/shutdown.sh), then restart Tomcat (bin/startup.sh). On restart, Tomcat looks in its webapps directory, and deploys everything it finds there.

Q: Sure it's easy to tell Tomcat to shutdown and startup, but what about the web apps that are running? They all have to go down!

A: Technically, yes. Taking your web apps down so that you can redeploy one servlet is a little harsh, especially if you have a lot of traffic on your web site. But that's why most of the production-quality Web Containers let you do a hot redeploy, which means that you don't have to restart your server or take any other web apps down. In fact, Tomcat does include a manager tool that will let you deploy, undeploy, and redeploy entire web apps without restarting Tomcat. In a production environment, that's what you'd use. But for testing, it's easier to just restart Tomcat. Info on the management tool is at:

But in the real world, even a hot redeploy is a Big Deal, and taking even a single app down just because the init parameter value changed can be a bad idea. If the values of your init parameters are going to change frequently, you're better off having your servlet methods get the values from a file or database, but this approach will mean a lot more overhead each time your servlet code runs, instead of only once during initialization.
using ServletConfig

Testing your ServletConfig

ServletConfig's main job is to give you init parameters. It can also give you a ServletContext, but we'll usually get a context in a different way, and the getServletName() method is rarely useful.

In the DD (web.xml) file:

```xml
  <servlet>
    <servlet-name>BeerParamTests</servlet-name>
    <servlet-class>com.example.TestInitParams</servlet-class>
    <init-param>
      <param-name>adminEmail</param-name>
      <param-value>likewecare@wickedlysmart.com</param-value>
    </init-param>
    <init-param>
      <param-name>mainEmail</param-name>
      <param-value>blop@wickedlysmart.com</param-value>
    </init-param>
  </servlet>
  <servlet-mapping>
    <servlet-name>BeerParamTests</servlet-name>
    <url-pattern>/Tester.do</url-pattern>
  </servlet-mapping>
</web-app>
```

In a servlet class:

```java
package com.example;
import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;

public class TestInitParams extends HttpServlet {
  public void doGet(HttpServletRequest request, HttpServletResponse response) throws IOException, ServletException {
    Printwriter out = response.getWriter();
    out.println("<html>");
    Enumeration e = getServletConfig().getInitParameterNames();
    while(e.hasMoreElements()) {
      out.println("<b>param name = "+ e.nextElement() + "</b><br>");
    }
    out.println("<b>admin email is "+ getServletConfig().getInitParameter("adminEmail"));
  }
}
```

154  chapter 5
attributes and listeners

How can a JSP get servlet init parameters?

A ServletConfig is for servlet configuration (it doesn’t say JSPConfig). So if you want other parts of your application to use the same info you put in the servlet’s init parameters in the DD, you need something more.

What about the way we did it with the beer app? We passed the model info to the JSP using a request attribute...

```java
// inside the doPost() method
String color = request.getParameter("color");
BeerExpert be = new BeerExpert();
List result = be.getBrands(color);
request.setAttribute("styles", result);
```

We could do it this way. The request object lets you set attributes (think of them as a name/value pair where the value can be any object) that any other servlet or JSP that gets the request can use. That means any servlet or JSP to which the request is forwarded using a RequestDispatcher.

We’ll look at RequestDispatcher in detail at the end of this chapter, but for now all we care about is getting the data (in this case the email address) to the pieces of the web app that need it, rather than just one servlet.
Setting a request attribute works... but only for the JSP to which you forwarded the request

With the beer app, it made sense to store the model info for the client’s request in the request object, because the next step was to forward the request to the JSP responsible for creating the view. Since that JSP needed the model data and the data was relevant to only that particular request, everything was fine.

But that doesn’t help us with the email address, because we might need to use it from all over the application! There is a way to have a servlet read the init parameters and then store them in a place other parts of the app could use, but then we’d have to know which servlet would always run first when the app is deployed, and any changes to the web app could break the whole thing. No, that won’t do either.
Context init parameters to the rescue

Context init parameters work just like servlet init parameters, except context parameters are available to the entire webapp, not just a single servlet. So that means any servlet and JSP in the app automatically has access to the context init parameters, so we don’t have to worry about configuring the DD for every servlet, and when the value changes, you only have to change it one place!

In the DD (web.xml) file:

```
<servlet>
  <servlet-name>BeerParamTests</servlet-name>
  <servlet-class>TestInitParam</servlet-class>
</servlet>

<context-param>
  <param-name>adminEmail</param-name>
  <param-value>clientheader@wickedlysmart.com</param-value>
</context-param>
```

In the servlet code:

```
out.println(getServletContext().getInitParameter("adminEmail"));
```

Every servlet inherits a `getServletContext()` method (and JSPs have special access to a context as well).

OR:

```
ServletContext context = getServletContext();
out.println(context.getInitParameter("adminEmail"));
```

You give it a param-name and param-value just like with servlet init parameters, except this time it’s in the `<context-param>` element instead of `<init-param>`. For the WHOLE app, so it’s not nested `<context-param>` inside the `<servlet>` element!! But out BUT OUTSIDE any `<servlet>` declaration.

IMPORTANT!! The `<context-param>` is for the WHOLE app, so it’s not nested `<context-param>` inside the `<servlet>` element!! But out BUT OUTSIDE any `<servlet>` declaration.

We took the `<init-param>` element out of the `<servlet>` element.

Here we broke out the code into TWO steps— getting the ServletContext reference, and calling its getInitParameter() method.
context vs. servlet init parameters

Remember the difference between servlet init parameters and context init parameters

Here’s a review of the key differences between context init parameters and servlet init parameters. Pay special attention to the fact that they’re both referred to as init parameters, even though only servlet init parameters have the word “init” in the DD configuration.

<table>
<thead>
<tr>
<th>Context init parameters</th>
<th>Servlet init parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Within the &lt;web-app&gt; element but NOT within a specific &lt;servlet&gt; element</td>
<td>Within the &lt;servlet&gt; element for each specific servlet</td>
</tr>
<tr>
<td>&lt;web-app&gt;...&gt;</td>
<td>&lt;servlet&gt;</td>
</tr>
<tr>
<td>&lt;context-param&gt;</td>
<td>&lt;servlet-name&gt;</td>
</tr>
<tr>
<td>&lt;param-name&gt;foo&lt;/param-name&gt;</td>
<td>&lt;app-name&gt;</td>
</tr>
<tr>
<td>&lt;param-value&gt;bar&lt;/param-value&gt;</td>
<td>&lt;servlet-name&gt;</td>
</tr>
<tr>
<td>&lt;/context-param&gt;</td>
<td>&lt;servlet-class&gt;</td>
</tr>
<tr>
<td>&lt;!-- other stuff including servlet declarations --&gt;</td>
<td>&lt;init-param&gt;</td>
</tr>
<tr>
<td>&lt;/web-app&gt;</td>
<td>&lt;param-name&gt;foo&lt;/param-name&gt;</td>
</tr>
<tr>
<td>Notice it doesn’t say “init” anywhere in the DD for context init parameters, the way it does for servlet init parameters.</td>
<td>&lt;param-value&gt;bar&lt;/param-value&gt;</td>
</tr>
<tr>
<td>&lt;/web-app&gt;</td>
<td>&lt;/init-param&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;!-- other stuff --&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;/servlet&gt;</td>
</tr>
</tbody>
</table>

**Servlet Code**

```
getServletContext().getInitParameter("foo");
getServletConfig().getInitParameter("foo");
```

It’s the same method name!

**Availability**

To any servlets and JSPs that are part of this web app.  

To only the servlet for which the <init-param> was configured.  

(Although the servlet can choose to make it more widely available by storing it in an attribute.)
**ServletConfig is one per servlet**

**ServletContext is one per web app**

There's only one ServletContext for an entire web app, and all the parts of the web app share it. But each servlet in the app has its own ServletConfig. The Container makes a ServletContext when a web app is deployed, and makes the context available to each Servlet and JSP (which becomes a servlet) in the web app.

---

**Web app initialization:**

- Container reads the DD and creates a name/value String pair for each `<context-param>`.
- Container creates a new instance of ServletContext.
- Container gives the ServletContext a reference to each name/value pair of the context init parameters.
- Every servlet and JSP deployed as part of a single web app has access to that same ServletContext.

---

**If the app is distributed, there's one ServletContext per JVM!**

If your application is distributed across multiple servers (probably in a clustered environment), your web app really COULD have more than one ServletContext. A ServletContext is *only* per app, but only if the app is in a single JVM! In a distributed environment, you'll have *one* ServletContext per JVM. Now, chances are this won't create problems, but if you have a distributed web app, you better consider the consequences of having different contexts for each JVM.
Dumb Questions

Q: What’s with the inconsistent naming scheme? How come the DD elements are <context-param> and <init-param> but in the servlet code, BOTH use the getInitParameter() method?

A: They didn’t ask us to help them come up with the names. If they had, of course, we’d have said it should be getInitParameter[] and getContextParameter[], to match the XML elements in the DD. Or, they could have used different XML elements—perhaps <servlet-init-param> and <context-init-param>. But no, that would have sucked all the fun out of trying to keep them straight.

Q: Why would I ever use <init-param> anyway? Wouldn’t I always want to use <context-param> so that other parts of my app could reuse the values and I won’t have to duplicate XML code for every servlet declaration?

A: It all depends on which part of your app is supposed to see the value. Your application logic might require you to use a value that you want to restrict to only an individual servlet. But typically, developers find app-wide context init parameters a lot more helpful than servlet-specific servlet init parameters. Perhaps the most common use of a context parameter is storing database lookup names. You’d want all parts of your app to have access to the correct name, and when it changes, you want to change it in only one place.

Q: What happens if I give a context init parameter the same name as a servlet init parameter in the same web app?

A: The molecular-sized black hole miraculously created in a research facility in New Jersey will slip from its containment field, plummet to the earth’s core, and destroy the planet.

Q: If you modify the XML to change the value of an init parameter (either servlet or context), when does the servlet or the rest of the web app see the change?

A: ONLY when the web app is redeployed. Remember—we talked about this before—the servlet is initialized only once, at the beginning of its life, and that’s when it’s given its ServletConfig and ServletContext. The Container reads the values from the DD when it creates those two objects, and sets the values.

Q: Can’t I get around this by setting the values at runtime? Sure there’s an API that’ll let me change those values dynamically...

A: No, there’s not. Look in ServletContext or ServletConfig and you’ll find a getter (getInitParameter()), but you won’t find a setter. There’s no setInitParameter().

Q: That’s lame.

A: These are init parameters. Init from the Latin word initialization. If you think of them purely as deploy-time constants, you’ll have the right perspective. In fact, that’s so important we’re going to say it again in a bolder way:

Think of init parameters as deploy-time constants!

You can get them at runtime, but you can’t set them. There’s no setInitParameter().

Or maybe nothing, because there’s no name space conflict since you get the parameters through two different objects (ServletContext or ServletConfig).
**Code Magnets**

Rearrange the magnets to form a DO that declares a parameter that matches the servlet code:

```java
getServletContext().getInitParameter("foo");
```

You won't use all of the magnets!

(Note: when you see `<web-app ...>`, remember that this is our short-cut to save space on the page. You can't deploy a web.xml file unless the `<web-app>` tag has all the attributes it needs.)

---

**Exercise**

If you see “init parameter” without knowing if it means servlet init parameter, assume servlet.

Some people use the phrase “init parameter” to mean “servlet init parameter”, and they use “context parameter” or even “application parameter” to mean “context init parameter”. So, even though BOTH are initialization parameters, and both come from the getInitParameter() method, remember that only SERVLET init parameters are listed in the DO as init parameters, so the phrase “init parameter” means “servlet init parameter” by default.

We know that as a developer, you'll be kinder to others and always say explicitly whether an init parameter is a servlet init parameter or a context init parameter.
So what else can you do with your ServletContext?

A ServletContext is a JSP or servlet’s connection to both the Container and the other parts of the web app. Here are some of the ServletContext methods. We put the ones you should know for the exam in bold.

```java
javax.servlet.ServletContext

// get/init parameters and set/get attributes

getInitParameter(String)
getInitParameterNames()
getAttribute(String)
getAttributeNames()
setAttribute(String)
removeAttribute(String)

// get info about the server/container

getMajorVersion()
getServerInfo()

getRealPath(String)
getResourceAsStream(String)

getRequestDispatcher(String)

log(String)
// more methods
```

Before I come into your life, you were just another laser object instead of a real servlet.
**attributes and listeners**

A servlet’s `ServletConfig` object always holds a reference to the `ServletContext` for that servlet. So don’t be fooled if you see servlet code on the exam that says:

```java
getServletConfig().getServletContext().getInitParameter()
```

Not only is that legal, but it does the same thing as:

```java
this.getServletContext().getInitParameter()
```

In a servlet, the only time you would NEED to go through your `ServletConfig` to get your `ServletContext` is if you’re in a Servlet class that doesn’t extend `HttpServlet` or `GenericServlet` (the `getServletConfig()` method you inherit comes from `GenericServlet`). But the chance of ANYONE using a non-HTTP servlet is, well, asymptotically approaching zero. So just call your own `getServletContext()` method, but don’t be dazed or confused if you see code that uses the `ServletConfig` to get the context.

But what if the code in side some class that is NOT a servlet (a helper/utility class, for example)? Someone might have pasted a `ServletConfig` to that class, and the class code would have to use `getServletContext()` to get a reference to the `ServletContext` object.

---

**Q:** How do all the parts of a web app get access to their own `ServletContext`?

**A:** For servlets, you already know: call your inherited `getServletContext()` method.

For JSPs it’s a little different—JSPs have something called `implicit objects`; and `ServletContext` is one of them. You’ll see exactly how a JSP uses a `ServletContext` when we get to the JSP chapters.

**Q:** So you get built-in logging through your context? That sounds VERY helpful!

**A:** Um, no. Not unless you have a really small, simple web app. There are much better ways to do logging. The most popular, robust logging mechanism is Log4j; you can find it on the Apache site at:

```
http://jakarta.apache.org/log4j
```

You can also use the logging API from `java.util.logging`, added to J2SE in version 1.4.

It’s fine to use the `ServletContext` `log()` method for simple experiments, but in a real production environment, you will almost certainly want to choose something else. There’s a good reference on web app logging with and without Log4j in the `Java Servlet & JSP Cookbook` from O’Reilly.

Logging is not part of the exam objectives, but it’s important. Fortunately, you’ll find the APIs easy to use.
context parameter limitations

What if you want an app init parameter that’s a database DataSource?

Context parameters can’t be anything except Strings. After all, you can’t very well stuff a Dug object into an XML deployment descriptor. (Actually, you could represent a serialized object in XML, but there’s no facility for this in the Servlet spec today... maybe in the future.)

What if you really want all the parts of your web app to have access to a shared database connection? You can certainly put the DataSource lookup name in a context init parameter, and that’s probably the most common use of context parameters today.

But then who does the work of turning the String parameter into an actual DataSource reference that all parts of the web app can share?

You can’t really put that code in a servlet, because which servlet would you choose to be The One To Lookup The DataSource And Store It In An Attribute? Do you really want to try to guarantee that one servlet in particular will always run first? Think about it.

FLEX YOUR MIND

How could you solve this problem?

How could you initialize a web app with an object? Assume that you need the String context init parameter in order to create that object (think about the database example).
attributes and listeners

Oh, if only there were a way to have something like a main method for my whole web app. Some code that always runs before ANY servlets or JSPs...

What she really wants is a listener.

She wants to listen for a context initialization event, so that she can get the context init parameters and run some code before the rest of the app can service a client.

She needs something that can be sitting there, waiting to be notified that the app is starting up.

But which part of the app could do the work? You don’t want to pick a servlet—that’s not a servlet’s job.

There’s no problem in a plain old standalone Java app, because you’ve got main(). But with a servlet, what do you do?

You need something else. Not a servlet or JSP, but some other kind of Java object whose sole purpose in life is to initialize the app (and possibly to uninitialize it too, cleaning up resources when it learns of the app’s demise...).

Chapter 5. Being a Web App

Head First Servlets and JSP by Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: O’Reilly

context listeners

She wants a ServletContextListener

We can make a separate class, not a servlet or JSP, that can listen for the two key events in a ServletContext's life—initialization (creation) and destruction. That separate class implements javax.servlet.ServletContextListener.

We need a separate object that can:

- Get notified when the context is initialized (app is being deployed).
  - Get the context init parameters from the ServletContext.
  - Use the init parameter lookup name to make a database connection.
  - Store the database connection as an attribute, so that all parts of the web app can access it.

- Get notified when the context is destroyed (the app is undeployed or goes down).
  - Close the database connection.

A ServletContextListener class:

```java
import javax.servlet.*;

public class MyServletContextListener implements ServletContextListener {
    public void contextInitialized(ServletContextEvent event) {
        // code to initialize the database connection
        // and store it as a context attribute
    }

    public void contextDestroyed(ServletContextEvent event) {
        // code to close the database connection
    }
}
```

166 chapter 5
attributes and listeners

OK, I have a listener class. Now what do I do? Where do I put the class? Who instantiates it? How do I register for the events? How does the listener set the attribute in the right ServletContext?

FLEX YOUR MIND

What do you think the mechanism might be for making a listener be part of a specific web app?

Hint: how do you tell the Container about the other parts of your web app? Where might the Container discover your listener?
using a ServletContextListener

**Tutorial: a simple ServletContextListener**

Now we’ll walk through the steps of making and running a ServletContextListener. This is just a simple test class so that you can see how all the pieces work together; we’re not using the database connection example because you’d have to set up a database to make it work. But the steps are the same regardless of the code you put in your listener callback methods.

*In this example, we’ll turn a String init parameter into an actual object—a Dog.* The listener’s job is to get the context init parameter for the dog’s breed (Beagle, Poodle, etc.), then use that String to construct a Dog object. The listener then sticks the Dog object into a ServletContext attribute, so that the servlet can retrieve it.

The point is that the servlet now has access to a shared application object (in this case a Dog), and doesn’t have to read the context parameters. Whether the shared object is a Dog or a database connection doesn’t matter. The key is to use the init parameters to create a single object that all parts of the app will share.

**Our Dog example:**

- The listener object asks the ServletContext object for a reference to the app’s ServletContext.
- The listener uses the reference to the ServletContext to get the context init parameter for “breed”, which is a String representing a dog breed.
- The listener uses that dog breed String to construct a Dog object.
- The listener uses the reference to the ServletContext to set the Dog attribute in the ServletContext.
- The tester servlet in this web app gets the Dog object from the ServletContext, and calls the Dog’s getBreed[] method.
Making and using a context listener

Maybe you’re still wondering how the Container discovers and uses the listener... You configure a listener the same way you tell the Container about the rest of your web app—through the web.xml Deployment Descriptor!

1. Create a listener class

   ```xml
   <Listener>
     ServletContextListener
     contextInitialized(ServletContextEvent)
     contextDestroyed(ServletContextEvent)
   </Listener>
   
   MyServletContextListener
   contextInitialized(ServletContextEvent)
   contextDestroyed(ServletContextEvent)
   
   To listen for ServletContext events, write a listener class that implements ServletContextListener, put it in your WEB-INF/classes directory, and tell the Container by putting a <listener> element in the Deployment Descriptor.
   ```

2. Put the class in WEB-INF/classes

   (This isn’t the ONLY place it can go... WEB-INF/classes is one of several places the Container can look for classes. We’ll cover the others in the Deployment chapter.)

3. Put a <listener> element in the web.xml Deployment Descriptor

   ```xml
   <listener>
     <listener-class>
       com.example.MyServletContextListener
     </listener-class>
   </listener>
   ```

Question for you—which part of the DD does the <listener> element go into? Does it go into a servlet element, or just under <web-app>?

Think about it.
**ServletContextListener tutorial**

**We need three classes and one DD**

For our context listener test example, we need to write the classes and the web.xml file.

For ease of testing, we’ll put all of the classes in the same package: `com.example`

1. **The ServletContextListener**

   **MyServletContextListener.java**
   
   This class implements ServletContextListener, gets the context init parameters, creates the Dog, and sets the Dog as context attribute.

2. **The attribute class**

   **Dog.java**
   
   The Dog class is just a plain old Java class. Its job is to be the attribute value that the ServletContextListener instantiates and sets in the ServletContext, for the servlet to retrieve.

3. **The Servlet**

   **ListenerTester.java**
   
   This class extends HttpServlet. Its job is to verify that the listener worked by getting the Dog attribute from the context, invoking getBreed() on the Dog, and printing the result to the response (so we’ll see it in the browser).
Writing the listener class

It works just like other types of listeners you might be familiar with, such as Swing GUI event handlers. Remember, all we need to do is get the context init parameters to find out the dog breed, make the Dog object, and put the Dog into the context as an attribute.

```java
package com.example;
import javax.servlet."
public class MyServletContextListener implements ServletContextListener {

    public void contextInitialized(ServletContextEvent event) {
        ServletContext sc = event.getServletContext();
        String dogBreed = sc.getInitParameter("breed");
        Dog d = new Dog(dogBreed);
        sc.setAttribute("dog", d);
    }

    public void contextDestroyed(ServletContextEvent event) {
        // nothing to do here
    }
}
```

attributes and listeners

Implement javax.servlet.ServletContextListener.
Ask the event for the ServletContext.
Use the context to get the init parameter.
Make a new Dog.
Use the context to set an attribute (a name/object pair) that is the Dog. Now other parts of the app will be able to get the value of the attribute (the Dog).

We don’t need anything here. The Dog doesn’t need to be cleaned up. When the context goes away, it means the whole app is going down, including the Dog.
Writing the attribute class (Dog)

Oh yeah, we need a Dog class—the class representing the object we’re going to store in the ServletContext, after reading the context init parameters.

```java
package com.example;
public class Dog {
    private String breed;
    public Dog(String breed) {
        this.breed = breed;
    }
    public String getBreed() {
        return breed;
    }
}
```

(We’ll use the context init parameter as the argument for the Dog constructor.)

Our servlet will get the Dog from the context (the Dog that the listener sets as an attribute), call the Dog’s getBreed() method, and print out the breed in the response so we can see it in the browser.

Q: I thought I read somewhere that servlet attributes had to be Serializable...

A: Interesting question. There are several different attribute types, and whether the attribute should be Serializable only matters with Session attributes. And the scenario in which it matters is only if the application is distributed across more than one JVM. We’ll talk all about that in the Sessions chapter.

There’s no technical need to have any attributes (including Session attributes) be Serializable, although you might consider making all of your attributes Serializable by default, unless you have a really good reason NOT to.

Think about it—are you really certain that nobody will ever want to use objects of that type as arguments or return values as part of a remote method call? Can you really guarantee that anyone who uses this class (Dog, in this case) will never run in a distributed environment?

So, although you aren’t required to make any attributes Serializable, you probably should if you can.
Chapter 5. Being a Web App

Writing the servlet class

This is the class that tests the ServletContextListener. If everything is working right, by the time the Servlet's doGet() method runs for the first time, the Dog will be waiting as an attribute in the ServletContext.

```java
package com.example;
import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;

public class ListenerTester extends HttpServlet {
    public void doGet(HttpServletRequest request, HttpServletResponse response)
        throws IOException, ServletException {
        response.setContentType("text/html");
        PrintWriter out = response.getWriter();
        out.println("test context attributes set by listener<br>");
        out.println("<br>");
        Dog dog = (Dog) getServletContext().getAttribute("dog");
        // don't forget the cast!!
        out.println("Dog's breed is: " + dog.getBreed());
    }
}
```

attributes and listeners

Nothing special so far... just a regular servlet.

Now we get the Dog from the ServletContext. If the listener worked, the Dog will be there BEFORE this service method is called for the first time.

If things didn't work, THIS is where we'll find out... we'll get a big fat NullPointerException if we try to call getBreed() and there's no Dog.

get Attribute() returns type Object!! You need to cast the return!

But getInitParameter() returns a String. So you must cast the return of getAttribute(), but the return of getInitParameter() can be assigned directly to a String. So... don't be fooled by bad exam code that doesn't use a cast:

```java
Dog d = ctx.getAttribute("dog"); // Bad!!
```

If we try to cast a String to a Dog, and there's no Dog, we get a NullPointerException.

You are here > 173
configuring a listener in the DD

Writing the Deployment Descriptor

Now we tell the Container that we have a listener for this app, using the <listener> element. This element is simple—it needs only the class name. That’s it.

```
<web-app xmlns="http://java.sun.com/xml/ns/j2ee"
  xmlns xsi=http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee/web-app_2.4.xsd"
  version="2.4">
  <servlet>
    <servlet-name>ListenerTester</servlet-name>
    <servlet-class>com.example.ListenerTester</servlet-class>
  </servlet>
  <servlet-mapping>
    <servlet-name>ListenerTester</servlet-name>
    <url-pattern>ListenerTest.do</url-pattern>
  </servlet-mapping>
  <context-param>
    <param-name>breed</param-name>
    <param-value>Great Dane</param-value>
  </context-param>
  <listener>
    <listener-class>
      com.example.MyServletContextListener
    </listener-class>
  </listener>
</web-app>
```
Q: Hold on... how are you telling the Container that this is a listener for ServletContext events? There doesn’t seem to be an XML element for <listener-type> or anything that says what type of events this listener is for. But I noticed you have “ServletContextListener” as part of the class name—is that how the Container knows? By the naming convention?

A: No. There’s no naming convention. We just did it that way to make it painfully clear what kind of a class we wrote. The Container figures it out simply by inspecting the class and noticing the listener interface (or interfaces; a listener can implement more than one listener interface).

Q: Does that mean there are other types of listeners in the servlet API?

A: Yes, there are several other types of listeners that we’ll talk about in a minute.
**Compiling and Deploying the Listener Test**

**Compile and deploy**

Let’s get it all working. The steps are:

1. **Compile the three classes**
   They’re all in the same package...

2. **Create a new web app in Tomcat**
   - Create a directory named `listenerTest` and place it inside the Tomcat `webapps` directory.
   - Create a directory named `WEB-INF` and place it inside the `listenerTest` directory.
   - Put your `web.xml` file in the `WEB-INF` directory.
   - Make a `classes` directory inside `WEB-INF`.
   - Make a directory structure inside `classes` that matches your package structure: a directory called `com` that contains `example`.

3. **Copy your three compiled files into your web app directory structure in Tomcat**

   ```
   listenerTest/WEB-INF/classes/com/example/Dog.class
   listenerTest/WEB-INF/classes/com/example/ListenerTester.class
   listenerTest/WEB-INF/classes/com/example/ServletContextListener.class
   ```

4. **Put your `web.xml` Deployment Descriptor into the WEB-INF directory for this web app**

   ```
   listenerTest/WEB-INF/web.xml
   ```

5. **Deploy the app by shutting down and restarting Tomcat**

   176 chapter 5
Try it out

Bring up your browser and let’s hit the servlet directly. We didn’t bother making an HTML page, so we’ll access the servlet by typing in the URL from the servlet mapping in the DD (ListenTest.do).

![Image showing a browser with a URL and dog's breed attributes.

Test context attributes set by listener

Dog’s breed is: Great Dane

Troubleshooting

If you get a NullPointerException, you didn’t get a Dog back from getAttribute(). Check the String name used in setAttribute() and make sure it matches the String name you’re using in getAttribute().

Recheck your web.xml and make sure the <listener> is registered.

Try looking at the server logs and see if you can find out if the listener is actually being called.

To make it as confusing as possible, we gave everything a subtly different name. We want to make sure you’re paying attention to how these names are used, and when you name everything the same, it’s tough to tell how the names affect your app.

Servlet class name: ListenerTest.<class>
Web app directory name: listenerTest
URL pattern mapped to this the servlet: ListenTest.do

Be careful about whether it’s Listener or Listen, Test or Test.
how our context listener works

The full story...

Here’s the scenario from start (app initialization) to finish (servlet runs). You’ll see in step 11 we condensed the Servlet initialization into one big step.

1. Container reads the Deployment Descriptor for this app, including the <listener> and <context-param> elements.

2. Container creates a new ServletContext for this application, that all parts of the app will share.

3. Container creates a name/value pair of Strings for each context init parameter. Assume we have only one.

4. Container gives the ServletContext references to the name/value parameters.

5. Container creates a new instance of the MyServletContextListener class.

6. Container calls the listener’s contextInitialized() method, passing in a new ServletContextEvent. The event object has a reference to the ServletContext, so the event-handling code can get the context from the event, and get the context init parameter from the context.

---

Chapter 5. Being a Web App

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: O'Reilly  Prepub Date: 8/1/2004

Prepared for Stephen Goss, Safari ID: stephengoss@gmx.net

User number: 747221 Copyright 2007, Safari Books Online, LLC.
The story continues...

1. Listener asks ServletContextEvent for a reference to the ServletContext.

2. Listener asks ServletContext for the context init parameter "breed".

3. Listener uses the init parameter to construct a new Dog object.

4. Listener sets the Dog as an attribute in the ServletContext.

5. Container makes a new Servlet (i.e., makes a new ServletConfig with init parameters, gives the ServletConfig a reference to the ServletContext, then calls the Servlet's init() method).

6. Servlet gets a request, and asks the ServletContext for the attribute "dog".

7. Servlet calls getBreed() on the Dog (and prints that to the HttpServletResponse).
other listeners

I just thought of something... since attributes can be set programmatically (unlike init parameters), can I listen for attribute events? Like if someone adds or replaces a Dog?

Listeners: not just for context events...

Where there's a lifecycle moment, there's usually a listener to hear about it. Besides context events, you can listen for events related to context attributes, servlet requests and attributes, and HTTP sessions and session attributes.

Relax. You don't have to know all of the listener API.

Other than ServletContextListener, you really don't need to memorize the methods of each of the listener interfaces. But... you DO need to know the kinds of events that you can listen for.

The exam objectives are clear: you'll be given a scenario (a developer's goal for an application) and you'll need to decide which is the right type of listener, or whether it's even POSSIBLE to be notified of that lifecycle event.

Note: we don't talk about sessions until the next chapter, so don't worry about it if you don't yet know what an HTTP session is or why you care.
# Pick the Listener

Match the scenario on the left with the listener interface (at the bottom of the page) that supports that goal. Use each interface only once. *Yes, we KNOW we haven’t looked at these yet. See what you can come up with just by looking at the names. Answers are on the next page, so don’t peek!*

<table>

The HttpSessionBindingListener

You might be confused about the difference between an HttpSessionBindingListener and an HttpSessionAttributeListener. (Well, not you, but someone you work with.) A plain old HttpSessionAttributeListener is just a class that wants to know when any type of attribute has been added, removed, or replaced in a Session. But the HttpSessionBindingListener exists so that the attribute itself can find out when it has been added to or removed from a Session.

```java
package com.example;
import javax.servlet.http.*;

public class Dog implements HttpSessionBindingListener {
    private String breed;

    public Dog(String breed) {  
        this.breed = breed;
    }

    public String getBreed() {  
        return breed;
    }

    public void valueBound(HttpSessionBindingEvent event) {  
        // code to run now that I know I'm in a session
    }

    public void valueUnbound(HttpSessionBindingEvent event) {  
        // code to run now that I know I am no longer part of a session
    }
}
```

Q: OK. I get how it works. I get that the Dog (an attribute that’ll be added to a session) wants to know when it’s in or out of a session. What I don’t get is WHY.

A: If you know anything about Entity beans... then you can picture this capability as a kind of “poor man’s entity bean.” If you don’t know about entity beans, you should run to your nearest book store and buy two copies of Head First EJB (one for you, one for your significant other so you can share special moments discussing it).

In the meantime, here’s a way to think about it—imagine the Dog is a Customer class, with each active instance representing a single customer’s info for name, address, order info, etc. The real data is stored in an underlying database. You use the database info to populate the fields of the Customer object, but the issue is how and when do you keep the database record and the Customer info synchronized? You know that whenever a Customer object is added to a session, it’s time to refresh the fields of the Customer with this customer’s data from his record in the database. So the valueBound() method is like a kick that says, “Go load me up with fresh data from the database—just in case it changed since the last time I was used.” Then valueUnbound() is a kick that says, “Update the database with the value of the Customer object fields.”
### Remembering the Listeners

Do your best to fill in the slots in this table. Keep in mind that the listener interfaces and methods follow a consistent naming pattern (mostly). Answers are at the end of the chapter.

<table>
<thead>
<tr>
<th>Attribute listeners</th>
<th>Other lifecycle listeners</th>
</tr>
</thead>
<tbody>
<tr>
<td>Methods in all attribute listeners (except binding listener)</td>
<td>Lifecycle events related to sessions (excluding attribute-related events)</td>
</tr>
<tr>
<td>Lifecycle events related to requests (excluding attribute-related events)</td>
<td>Lifecycle events related to servlet context (excluding attribute-related events)</td>
</tr>
</tbody>
</table>

184 chapter 5
What, exactly, is an attribute?

We saw how the ServletContext listener created a Dog object (after getting the context init parameter) and was able to stick (set) the Dog into the ServletContext as an attribute, so that other parts of the app could get it.

Earlier, with the beer tutorial, we saw how the servlet was able to stick the results of the call to the model into the Request (usually HttpServletRequest) object as an attribute (so that the JSP/view could get the value).

An attribute is an object set (referred to as bound) into one of three other servlet API objects—ServletContext, HttpServletRequest (or ServletRequest), or HttpSession. You can think of it as simply a name/value pair (where the name is a String and the value is an Object) in a map instance variable. In reality, we don’t know or care how it’s actually implemented—all we really care about is the scope in which the attribute exists. In other words, who can see it and how long does it live.

An attribute is like an object pinned to a bulletin board. Somebody stuck it on the board so that others can get it.

The big questions are: who has access to the bulletin board, and how long does it live? In other words, what is the scope of the attribute?
Attributes are not parameters!

If you’re new to servlets, you might need to spend some time reinforcing the difference between attributes and parameters. Rest assured that when we created the exam we spent just that little bit of extra time trying to make sure we made attribute and parameter questions as confusing as possible.

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Types</td>

<td>Request parameters</td>
</tr>
<tr>
<td>Session</td>
<td>Servlet init parameters</td>
</tr>
<tr>
<td>Method to set</td>
<td>You CANNOT set Application and Servlet init parameters—they’re set in the DD, remember? (With Request parameters, you can adjust the query String, but that’s different.)</td>
</tr>
<tr>
<td>Return type</td>
<td>String ← Big difference!</td>
</tr>
<tr>
<td>Object</td>
<td></td>
</tr>
<tr>
<td>Method to get</td>
<td></td>
</tr>
<tr>
<td>getAttribute(String name)</td>
<td>getInitParameter(String name)</td>
</tr>
</tbody>
</table>

*It’s true. If we’d made the exam simple and straightforward and easy, you wouldn’t feel that sense of pride and accomplishment from passing the exam. Making the exam difficult enough to ensure that you’d need to buy a study guide in order to pass it was never, EVER, a part of our thinking. No, seriously. We were just thinking of you.
The Three Scopes: Context, Request, and Session

Context Attributes

Accessible to only those in the application has access

Session Attributes

Accessible to only those with access to a specific HttpSession

REQUEST Attributes

Accessible to only those with access to a specific HttpServletRequest

attributes and listeners
**Attribute Scope**

Do your best to fill in the slots in this table. You REALLY need to understand attribute scope for the exam (and the real world) because you have to know which scope is the best to use for a given scenario. You'll see the answer in a few pages, but don't look ahead! If you're going to take the exam, trust us... you need to fill this out yourself by taking the time to think it through.

<table>
<thead>
<tr>
<th>Context</th>
<th>Accessibility (who can see it)</th>
<th>Scope (how long does it live)</th>
<th>What it's good for</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>HttpSession</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Request</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(Note: you should think about the implications of garbage collection when you think about scope - some attributes won’t be GC’d until the application is undeployed or dies. There’s nothing on the exam about designing with memory management in mind, but it’s something to be aware of).
**Attribute API**

The three attribute scopes—context, request, and session—are handled by the ServletContext, HttpServletRequest, and HttpSession interfaces. The API methods for attributes are exactly the same in every interface.

```java
Object.getAttribute(String name)
setAttribute(String name, Object value)
removeAttribute(String name)
getAttributes() // MANY more methods...
```

---

**Context**

```java
public interface ServletContext {
    getInitParameter(String)
    getInitParameterNames()
    getAttribute(String)
    setAttribute(String, Object)
    removeAttribute(String)
    getAttributeNames()
    getMajorVersion()
    getServerInfo()
    getRealPath(String)
    getResourcesAsStream(String)
    getRequestDispatcher(String)
    log(String)
    // MANY more methods...
}
```

**Request**

```java
public interface ServletRequest {
    getContentType()
    getParameter()
    getAttribute(String)
    setAttribute(String, Object)
    removeAttribute(String)
    getAttributeNames()
    // MANY more methods...
}
```

**Session**

```java
public interface HttpSession {
    getAttribute(String)
    setAttribute(String, Object)
    removeAttribute(String)
    getAttributeNames()
    getServerInfo()
    getlastAccessedTime()
    // MANY more methods...
}
```

---

**attributes and listeners**

attribute strangeness

The dark side of attributes...

Kim decides to test out attributes. He sets an attribute and then immediately gets the value of the attribute and displays it in the response. His doGet() looks like this:

```java
public void doGet(HttpServletRequest request, HttpServletResponse response)
    throws IOException, ServletException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    out.println("test context attributes<br/>");
    request.setAttribute("foo", "22");
    request.setAttribute("bar", "42");
    out.println(request.getAttribute("foo"));
    out.println(request.getAttribute("bar"));
}
```

Here’s what he sees the first time he runs it.

It’s exactly what he expected.

![Screenshot of test context attributes](image)

```
test context attributes
22 42 Just what we expected.
```

190 chapter 5
But then something goes horribly wrong...

The second time he runs it, he’s shocked to see:

![Diagram of test context attributes]

FLEX YOUR MIND

Look closely at the code, and think about what’s happening. Do you see anything that could explain the problem?

You might not have enough info to solve the mystery, so here’s another clue: Kim put this code in a test servlet that’s part of a larger test web app. In other words, the servlet that holds this doGet() method was deployed as part of a larger app.

Now can you figure it out?

Can you think of how he might fix it?
There must be another servlet hitting the same context attribute...

Yikes! Another servlet that is part of the same web app, running in a separate thread can set the "bar" attribute. And that's not all: the Container might launch another thread for Servlet A to handle a third client.

Context scope isn't thread-safe!

That's the problem.

Remember, everyone in the app has access to context attributes, and that means multiple servlets. And multiple servlets means you might have multiple threads, since requests are concurrently handled, each in a separate thread. This happens regardless of whether the requests are coming in for the same or different servlets.
The problem in slow motion...

Here’s what happened to Kim’s test servlet.

1. **Servlet A sets the context attribute “foo” with a value of “22”.

   

2. **Servlet A sets the context attribute “bar” with a value of “42”.

   

3. **Thread B becomes the running thread (Thread A goes back to Runnable but not Running), and sets the context attribute “bar” with a value of “16”. (The 42 is now gone.)

   

4. **Thread A becomes the running thread again, and gets the value of “bar” and prints it to the response.

   

---

In between when servlet A set the value of “bar” and then got the value of “bar”, another servlet thread snuck in and set “bar” to a different value.

So by the time servlet A printed the value of “bar”, it had been changed to “16”.

---

getServletContext().setAttribute("foo", "22");
getServletContext().setAttribute("bar", "42");

out.println(getServletContext().getAttribute("foo"));
out.println(getServletContext().getAttribute("bar"));
threads and context attributes

How do we make context attributes thread-safe?

Let’s hear what some of the other developers have to say...

I’m thinking I could synchronize the doGet() method, but that doesn’t really feel right. But I don’t know what else to do.

Synchronizing on the doGet() means kissing your concurrency goodbye. If you synchronize doGet(), it means that servlet can handle only ONE client at a time!

Why didn’t the Servlet spec developers just synchronize the get and set attribute methods in ServletContext, to make the attributes thread-safe?

Of course they didn’t synchronize the methods in ServletContext. Geez... that would have meant that every call to get and set an attribute would have all the synchronization overhead. What a huge waste if you don’t need it. No, protecting attributes is your OWN problem... don’t expect the API to save you. (I can’t even believe she suggested that.)

Chapter 5. Being a Web App
Synchronizing the service method is a spectacularly BAD idea

OK, so we know that synchronizing the service method will kill our concurrency, but it does give you the thread protection, right? Take a look at this legal code, and decide whether it would prevent the problem Kim had with the context attribute being changed by another servlet...

```java
public synchronized void doGet(HttpServletRequest request, HttpServletResponse response)
    throws IOException, ServletException {

    response.setContentType("text/html");
    PrintWriter out = response.getWriter();

    out.println("test context attributes<br>");
    ServletContext().setAttribute("foo", "22");
    ServletContext().setAttribute("bar", "42");

    out.println(ServletContext().getAttribute("foo"));
    out.println(ServletContext().getAttribute("bar"));
}
```

This can't work! Well, it's legal as a servlet, but I don't see how this will fix the problem...

Synchronizing the service method is a spectacularly BAD idea...

What do you think? Will it fix the problem Kim had? Look back at the code and the diagrams if you're not sure.
Synchronizing the service method won’t protect a context attribute!

Synchronizing the service method means that only one thread in a servlet can be running at a time... but it doesn’t stop other servlets or JSPs from accessing the attribute!

Synchronizing the service method would stop other threads from the same servlet from accessing the context attributes, but it won’t do anything to stop a completely different servlet.

\[\textit{don’t synchronize} \text{ the service method}\]

If you synchronize the service method, you WILL stop the Container from starting any other methods for new requests coming into servlet A. So this WILL protect the context attributes from being accessed by more than one thread running a service method of Servlet A.

But you won’t do anything to stop OTHER servlets! Regardless of whether the service methods in other servlets are synchronized or not... it still means other parts of the app have access to the context attributes.
You don't need a lock on the servlet…

you need the lock on the context!

The typical way to protect the context attribute is to synchronize ON the context object itself. If everyone accessing the context has to first get the lock on the context object, then you’re guaranteed that only one thread at a time can be getting or setting the context attribute. But…

there’s still an if there. It only works if all of the other code that manipulates the same context attributes ALSO synchronizes on the ServletContext. If code doesn’t ask for the lock, then that code is still free to hit the context attributes. But if you’re designing the web app, then you can decide to make everyone ask for the lock before accessing the attributes.

public void doGet(HttpServletRequest request, HttpServletResponse response)
throws IOException, ServletException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    out.println("<html>
    <head>
    </head>
    <body>
    <h2>attributes and listeners</h2>
    <p><b>You don't need a lock on the servlet…
        you need the lock on the context!</b></p>
    <p>The typical way to protect the context attribute is to synchronize ON the context object itself. If everyone accessing the context has to first get the lock on the context object, then you’re guaranteed that only one thread at a time can be getting or setting the context attribute. But…

    &lt;/html&gt;
    </pre>
Are Session attributes thread-safe?

Think about it.

We haven’t talked about HTTP sessions in detail yet (we will in the Sessions chapter), but you already know that a session is an object used to maintain conversational state with a client. The session persists across multiple requests from the same client. But it’s still just one client we’re talking about.

And if it’s one client, and a single client can be in only one request at a time, doesn’t that automatically mean that sessions are thread-safe? In other words, even if multiple servlets are involved, at any given moment there’s only one request from that particular client... so there’s only one thread operating on that session at a time. Right?

Even though both servlets can access the Session attributes in separate threads, each thread is a separate request. So it looks safe.

Unless...

Can you think of a scenario in which there could be more than one request at the same time, from the same client?

What do you think? Are session attributes guaranteed thread-safe?
What’s REALLY true about attributes and thread-safety?

We know that context attributes are inherently not safe, because all pieces of the app can access context attributes, from any request (which means any thread).

Very good. Now what about Session attributes. Are they safe?

You have much to learn, grasshopper. You do not know the truth about session attributes. Meditate on this before speaking again.

You must think outside the Container.
Color outside the lines. Run with scissors.

Yes! The Container can see the request from the second window as coming from the same session.

And how would you protect these session attributes from the havoc of multiple threads?

That is good, yes, but synchronize on what?

Yes master. And I know that synchronizing the service method is not a solution, because although it will stop that servlet from servicing more than one request at a time, it will NOT stop other servlets and JSPs in the same web app from accessing the context.

Yes master. They are for only one client, and the laws of physics prevent a client from making more than one request at a time.

But master, I have meditated and still I do not know how one client could have more than one request...

Very wise advice, master! I have it! The client could open a new browser window! So the Container can still use the same session for a client, even though it’s coming from a different instance of the browser?

So Session attributes are not thread-safe, and they too, must be protected. I will meditate on this...

Ah... I must synchronize the part of my code that accesses the session attributes. Just the way we did for the context attributes.

I must synchronize on the HttpSession!
Protect session attributes by synchronizing on the HttpSession

Look at the technique we used to protect the context attributes. What did we do?
You can do the same thing with session attributes, by synchronizing on the HttpSession object!

```java
public void doGet(HttpServletRequest request, HttpServletResponse response) throws IOException, ServletException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    out.println("test context attributes<br>
HttpServletRequest session = request.getSession();
    synchronized (session) {
        session.setAttribute("foo", "22");
        session.setAttribute("bar", "45");
        out.println(session.getAttribute("foo");
        out.println(session.getAttribute("bar");
    }
}
```

Q: Isn't this overkill? Is this really a possibility...that a client will open another browser window?

A: Of course it is. Surely you’ve done this yourself without a second thought—opened a second window because you were tired of waiting for the other one to respond, or because you minimized one, or misplaced the window without realizing it, etc. The point is, you can’t take the chance if you need thread-safety for your session variables. You have to know that it’s quite possible for a session-scoped attribute to be used by more than one thread at a time.

Q: Isn’t it a bad idea to synchronize code, because it causes a lot of overhead and hurts concurrency?

A: You should ALWAYS think carefully before synchronizing any code, because you’re right—it does add some expense in checking, acquiring, and releasing locks. If you need protection, then use synchronization but remember the standard rule of all forms of locking—keep the lock for the shortest amount of time to accomplish your goal! In other words, don’t synchronize the code that doesn’t access the protected state. Make your synchronized block as small as possible. Get the lock, get in, get what you need, and get the heck out so the lock can release and other threads can run that code.
The evils of SingleThreadModel

Although it’s not on the exam (because it’s evil), you’ve probably heard of or even used the now-deprecated SingleThreadModel interface, so we feel compelled to mention it while simultaneously reinforcing its evilness.

The SingleThreadModel sounds good to newbies, at first glance, as a way to solve multi-threading problems. You simply have your servlet implement the SingleThreadModel interface and BOOM—as if by magic your servlet will never have more than one thread at a time running. In other words, you’ve reduced your servlet to a single thread. Goodbye multi-threading problems, right?

No, of course not. You already know why... implementing SingleThreadModel is no different than synchronizing the service method—all you’ve done is demolished your concurrency without protecting attribute state! Because again, even if all your servlets implement SingleThreadModel, you can still have two servlets (each one dutifully running only one client request thread at a time) in the same web app, accessing context attributes at the same time.

SingleThreadModel offers nothing but poor performance if your application has more than one component. Since it misled thousands of new developers into thinking that SingleThreadModel gave them thread-safety, it’s been deprecated and the developers who use it now are subject to ridicule and humiliation.

But now you know, and you would never have used it anyway, since you already know that restricting a single servlet to a single thread protects you only if your entire application consists of a single servlet.

So, if you catch anybody using SingleThreadModel, revoke their Servlet license (and insist, no, demand that they buy a copy of this book).
request attributes are thread-safe

Only Request attributes and local variables are thread-safe!

That’s it. (We include method parameters when we say “local variables”). Everything else is subject to manipulation by multiple threads, unless you do something to stop it.

Q: So instance variables aren’t thread-safe?
A: That’s right. If you have multiple clients making requests on that servlet, that means multiple threads running that servlet code. And all threads have access to the servlet’s instance variables, so instance variables aren’t thread-safe.

Q: But they WOULD be thread-safe if you implemented the SingleThreadModel, right?
A: Yes, because you’d never have more than one thread for that servlet, so the instance variables would be thread-safe. But of course nobody would ever allow you into the servlets club ever again.

Q: I was just talking hypothetically. As in, “if someone WERE stupid enough to implement SingleThreadModel...” Not that I would ever do it. But while we’re being hypothetical... if I have a friend who, say, synchronizes the service method, wouldn’t that ALSO make the instance variables thread-safe?
A: Yes. But your friend would be an idiot. The effect of implementing SingleThreadModel is virtually the same as synchronizing the service method. Both can bring a web app to its knees without protecting the session and attribute state.

Q: But if you’re not supposed to use SingleThreadModel or synchronize the service method, then how DO you make instance variables thread-safe?
A: You don’t! Look at a well-written servlet, and chances are you won’t find any instance variables. Or at least any that are non-final. (And since you’re a Java programmer you know that even a final variable can still be manipulated unless it’s immutable.) So just don’t use instance variables if you need thread-safe state, because all threads for that servlet can step on instance variables.

Q: Then what SHOULD you use if you need multiple instances of the servlet to share something?
A: Stop right there! You said “multiple instances of the servlet.” We know you didn’t mean that, because there is always only ONE instance of the servlet. One instance, many threads.

If you want all the threads to access a value, decide which attribute state makes the most sense, and store the value in an attribute. Chances are, you can solve your problems in one of two ways:

1) Declare the variable as a local variable within the service method, rather than as an instance variable. OR
2) Use an attribute in the most appropriate scope.
Request attributes make sense when you want some other component of the app to take over all or part of the request. Our typical, simple example is an MVC app that starts with a servlet controller, but ends with View. The controller communicates with the model, and gets back data that the view needs in order to build the response. There's no need to put the data in a context or session attribute, since it applies only to this request, so we put it in the request scope. So how do we make another part of the component take over the request? With a RequestDispatcher.

```java
// code in a doGet()
BeerExpert be = new BeerExpert();
ArrayList result = be.getBrands();
request.setAttribute("styles", result);

RequestDispatcher view = request.getRequestDispatcher("Result.jsp");
view.forward(request, response);
```

Tell JSP to take over the request, and, oh yeah, here are the Request and Response objects.

1. The Beer servlet calls the getBrands() method on the model that returns some data that the view needs.

2. The servlet sets a Request attribute named "styles". (First it puts "Moose Drool" into an ArrayList.)

3. The servlet asks the HttpServletRequest for a RequestDispatcher, passing in a relative path to the view JSP.

4. The servlet calls forward() on the RequestDispatcher, to tell the JSP to take over the request. (Not shown: the JSP gets the forwarded request, and gets the "styles" attribute from the Request scope.)

attributes and listeners
RequestDispatcher revealed

RequestDispatchers have only two methods—forward() and include(). Both take the request and response objects (which the component you’re forwarding to will need to finish the job). Of the two methods, forward() is by far the most popular. It’s very unlikely you’ll use the include method from a controller servlet; however, behind the scenes the include method is being used by JSPs in the <jsp:include> standard action (which we’ll review in chapter 8). You can get a RequestDispatcher in two ways from the request or from the context. Regardless of where you get it, you have to tell it the web component to which you’re forwarding the request. In other words, the servlet or JSP that’ll take over.

Getting a RequestDispatcher from a ServletRequest

```java
RequestDispatcher view = request.getRequestDispatcher("result.jsp");
```

The `getRequestDispatcher()` method in ServletRequest takes a String path for the resource to which you’re forwarding the request. If the path starts with a forward slash ("/"), the Container sees that as “starting from the root of this web app”. If the path does NOT start with a forward slash, it’s considered relative to the original request. But you can’t try to trick the Container into looking outside the current web app. In other words, just because you have lots of "/.../" doesn’t mean it’ll work if it takes you past the root of your current web app!

Getting a RequestDispatcher from a ServletContext

```java
RequestDispatcher view = getServletContext().getRequestDispatcher("/result.jsp");
```

Like the equivalent method in ServletRequest, this `getRequestDispatcher()` method takes a String path for the resource to which you’re forwarding the request, EXCEPT you cannot specify a path relative to the current resource (the one that received this request). That means you must start the path with a forward slash!

Calling forward() on a RequestDispatcher

```java
view.forward(request, response);
```

Simple. The RequestDispatcher you got from your context or request knows the resource you’re forwarding to—the resource (servlet, JSP) you passed as the argument to `getRequestDispatcher()`. So you’re saying, “Hey, RequestDispatcher, please forward this request to the thing I told you about earlier (in this case, a JSP), when I first got you. And here’s the request and response, because that new thing is going to need them in order to finish handling the request.”
What's wrong with this code?

What do you think? Does this RequestDispatcher code look like it will work the way you’d expect?

```java
public void doGet(HttpServletRequest request, HttpServletResponse response)
    throws IOException, ServletException {
    response.setContentType("application/jar");
    ServletContext ctx = getServletContext();
    InputStream is = ctx.getResourceAsStream("bookCode.jar");
    int read = 0;
    byte[] bytes = new byte[1024];
    OutputStream os = response.getOutputStream();
    while ((read = is.read(bytes)) != -1) {
        os.write(bytes, 0, read);
    }
    os.flush();
    RequestDispatcher view = request.getRequestDispatcher("result.jsp");
    view.forward(request, response);
    os.close();
}
```

You'll get a big, fat `IllegalStateException`!

Q: How come you didn’t talk about the `RequestDispatcher include()` method?

A: It’s not on the exam, for one thing. For another, we already mentioned that it’s not used much in the real world. But to satisfy your curiosity, the `include()` method sends the request to something else (typically another servlet) to do some work **and then comes back to the sender!** In other words, `include()` means asking for help in handling the request, but it’s not a complete hand-off. It’s a temporary, rather than permanent transfer of control. With `forward()`, you’re saying, “That’s it, I’m not doing anything else to process this request and response.” But with `include()`, you’re saying, “I want someone else to do some things with the request and response, but when they’re done, I want to finish handling the request and response myself (although I might decide to do another include or forward after that...”).
### listener exercise answers

#### Chapter 5. Being a Web App

<table>
<thead>
<tr>
<th><strong>Remembering the Listeners</strong></th>
<th><strong>ANSWERS</strong></th>
</tr>
</thead>
</table>
| **Attribute listeners**       | ServletRequestAttributeListener  
                             | ServletContextAttributeListener  
                             | HttpSessionAttributeListener  |
| **Other lifecycle listeners** | ServletRequestListener       
                             | ServletContextListener         
                             | HttpSessionListener           
                             | HttpSessionBindingListener    
                             | HttpSessionActivationListener |
| **Methods in all attribute listeners (except binding listener)** | attributeAdded()  
                             | attributeRemoved()            
                             | attributeReplaced()           |
| **Lifecycle events related to sessions (excluding attribute-related events)** | when the session is created, and when it's destroyed  
                             | sessionCreated()              
                             | sessionDestroyed()            |

(Notice that the only difference between these and the attribute listeners is the word “Attribute” inserted in the interface name.)

| **Lifecycle events related to requests (excluding attribute-related events)** | when the request is initialized or destroyed  
                             | requestInitialized()    
                             | sessionDestroyed()       |

(Notice the difference between the session and request events—session is sessionCreated(), request is requestInitialized.)

| **Lifecycle events related to servlet context (excluding attribute-related events)** | when the context is initialized or destroyed  
                             | contextInitialized()      
                             | contextDestroyed()        |

206 chapter 5
### Attribute Scope

#### Accessibility (who can see it)
- **Context** (NOT thread-safe): Any part of the web app including servlets, JSPs, ServletContextListeners, ServletContextAttributeListener.
- **HttpSession** (NOT thread-safe): Any servlet or JSP with access to this particular session. Remember, a session extends beyond a single client request to span multiple requests by the same client, which could go to different servlets.
- **Request** (Thread-safe): Any part of the application that has direct access to the Request object. That mostly means only the Servlets and JSPs to which the request is forwarded using a RequestDispatcher. Also Request-related listeners.

#### Scope (how long does it live)
- **Context**: Lifetime of the ServletContext, which means life of the deployed app. If server or app goes down, the context is destroyed (along with its attributes).
- **HttpSession**: The life of the session. A session can be destroyed programmatically or can simply time-out. (We'll go into the details in the Session Management chapter.)
- **Request**: The life of the Request, which means until the Servlet's service() method completes. In other words, for the life of the thread (stack) handling this request.

#### What it's good for
- **Context**: Resources you want the entire application to share, including database connections, JNDI lookup names, email addresses, etc.
- **HttpSession**: Data and resources related to this client's session, not just a single request. Something that requires an ongoing conversation with the client. A shopping cart is a typical example.
- **Request**: Passing model info from the controller to the view... or any other data specific to a single client request.
Configure a context parameter in the DD:

```xml
<web-app ...

  <servlet>
    <servlet-name>BeerTest</servlet-name>
    <servlet-class>com.wickedlysmart.BeerTest</servlet-class>
  </servlet>

  <context-param>
    <param-name/foo>foo</param-name>
    <param-value>bar</param-value>
  </context-param>

</web-app>
```

Not used:

```xml
<servlet-param>
</servlet-param>
```

<init-param> is used for servlet init parameters, not context init parameters. You find <init-param> ONLY inside a <servlet> element. There's no such thing as <servlet-param>.
When using a `RequestDispatcher`, the use of which methods can often lead to an `IllegalStateException`? (Choose all that apply.)

- A. read
- B. flush
- C. write
- D. getOutputStream
- E. getResourceAsStream

Which statements about `ServletContext` initialization parameters are true? (Choose all that apply.)

- A. They should be used for data that changes rarely.
- B. They should be used for data that changes frequently.
- C. They can be accessed using `ServletContext.getParameter()`.
- D. They can be accessed using `ServletContext.getInitParameter()`.
- E. They should be used for data that is specific to a particular servlet.
- F. They should be used for data that is applicable to an entire web application.
mock exam

3. Which types define the methods `getAttribute()` and `setAttribute()`? (Choose all that apply.)
   - A. HttpSession
   - B. ServletRequest
   - C. ServletResponse
   - D. ServletContext
   - E. ServletConfig
   - F. SessionConfig

4. If a servlet is invoked using the `forward` or `include` method of `RequestDispatcher`, which methods of the servlet’s request object can access the request attributes set by the container? (Choose all that apply.)
   - A. getCookie()
   - B. getAttribute()
   - C. getInputStream()
   - D. getRequestBody()
   - E. getRequestDispatcher()

5. Which calls provide information about initialization parameters that are applicable to an entire web application? (Choose all that apply.)
   - A. ServletConfig.getInitParameters()
   - B. ServletContext.getInitParameters()
   - C. ServletConfig.getInitParameterNames()
   - D. ServletContext.getInitParameterNames()
   - E. ServletConfig.getInitParameter(String)
   - F. ServletContext.getInitParameter(String)
6 Which statements about listeners defined in the `javax.servlet` package are true? (Choose all that apply.)

- A. A `ServletRequestListener` can be used to perform an action when a servlet response has been sent.
- B. An `HttpSessionListener` can be used to perform an action when an `HttpSession` has timed out.
- C. A `ServletContextListener` can be used to perform an action when the servlet context is about to be shut down.
- D. A `ServletRequestAttributeListener` can be used to perform an action when an attribute has been removed from a `ServletRequest`.
- E. A `ServletContextAttributeListener` can be used to perform an action when the servlet context has just been created and is available to service its first request.

7 Which is most logically stored as an attribute in session scope?

- A. A copy of a query parameter entered by a user.
- B. The result of a database query to be returned immediately to a user.
- C. A database connection object used by all web components of the system.
- D. An object representing a user who has just logged into the system.
- E. A copy of an initialization parameter retrieved from a `ServletContext` object.
mock exam

8 Given this code from an otherwise valid `HttpServlet` that has also been registered as a `ServletRequestAttributeListener`:

```java
public void doGet(HttpServletRequest req, HttpServletResponse res)
  throws IOException, ServletException {
    req.setAttribute("a", "b");
    req.setAttribute("a", "c");
    req.removeAttribute("a");
  }

public void attributeAdded(ServletRequestAttributeEvent ev) {
  System.out.println("A:" + ev.getName() + "->" + ev.getValue());
}

public void attributeRemoved(ServletRequestAttributeEvent ev) {
  System.out.println("A:" + ev.getName() + "->" + ev.getValue());
}

public void attributeReplaced(ServletRequestAttributeEvent ev) {
  System.out.println("A:" + ev.getName() + "->" + ev.getValue());
}
```

What logging output is generated?

- A: a->b P:a->b
- B: a->b M:a->c
- C: a->b P:a->b M:a->c
- D: a->b P:a->b P:a->null

9 When declaring a listener in the DD, which sub-elements of the `<listener>` element are required? (Choose all that apply.)

- A. `<description>`
- B. `<listener-name>`
- C. `<listener-type>`
- D. `<listener-class>`
- E. `<servlet-mapping>`
Which types of objects can store attributes? (Choose all that apply.)

- A. ServletConfig
- B. ServletResponse
- C. RequestDispatcher
- D. HttpServletRequest
- E. HttpSession

Which are true? (Choose all that apply.)

- A. When a web application is preparing to shutdown, the order of listener notification is not guaranteed.
- B. When listener-friendly events occur, listener invocation order is not predictable.
- C. The container registers listeners based on declarations in the deployment descriptor.
- D. Only the container can invalidate a session.

Which statements about RequestDispatcher are true (where applicable, assume the RequestDispatcher was not obtained via a call to getNamedDispatcher())? (Choose all that apply.)

- A. A RequestDispatcher can be used to forward a request to another servlet.
- B. The only method in the RequestDispatcher interface is forward().
- C. Parameters specified in the query string used to create a RequestDispatcher are not forwarded by the forward() method.
- D. The servlet to which a request is forwarded may access the original query string by calling getQueryParameter() on the ServletRequest.
- E. The servlet to which a request is forwarded may access the original query string by calling getAttribute("javax.servlet.forward.query_string") on the...
mock exam

13 Which statements accurately describe how many instances of a servlet the servlet container instantiates for each web application? (Choose all that apply.)

- A. If the servlet implements `java.servlet.SingleThreadModel`, the container may create one instance for each request.
- B. If the servlet does not implement `SingleThreadModel`, the container may create multiple instances of the servlet in the same JVM.
- C. The `<load-on-startup>` `web.xml` element can determine how many instances are created.
- D. If the servlet does not implement `SingleThreadModel`, the container will create no more than one instance per JVM.

14 What is the recommended way to deal with servlets and thread safety?

- A. Write the servlet code to extend `ThreadSafeServlet`.
- B. Have the servlet implement `SingleThreadModel`.
- C. Log all servlet method calls.
- D. Use local variables exclusively, and if you have to use instance variables, synchronize access to them.
When using a RequestDispatcher, the use of which methods can often lead to an IllegalArgumentException? (Choose all that apply.)

- A. read
- B. flush
- C. write
- D. getOutputStream
- E. getResourceAsStream

Which statements about ServletContext initialization parameters are true? (Choose all that apply.)

- A. They should be used for data that changes rarely.
- B. They should be used for data that changes frequently.
- C. They can be accessed using ServletContext.getParameter().
- D. They can be accessed using ServletContext.getInitParameter().
- E. They should be used for data that is specific to a particular servlet.
- F. They should be used for data that is applicable to an entire web application.

An IllegalStateException is caused when a response has already been committed to the client (the flush method does that), and then you attempt a forward.

(Servlet v2.4 pg. 167)
mock answers

3. Which types define the methods `getAttribute()` and `setAttribute()`? (Choose all that apply.)

- A. HttpSession
- B. ServletRequest
- C. ServletResponse
- D. ServletContext
- E. ServletConfig
- F. SessionConfig

(Servlet v2.4 pg. 32, 33, 59)

4. If a servlet is invoked using the `forward` or `include` method of `RequestDispatcher`, which methods of the servlet’s request object can access the request attributes set by the container? (Choose all that apply.)

- A. `getCookies()` (Option B is the correct method. With it you can access the container populated `javax.servlet.forward.Xxx` and `javax.servlet.include.Xxxx` attributes)
- B. `getAttribute()`  
- C. `getRequestPath()`  
- D. `getAttribute()`  
- E. `getRequestDispatcher()`  

(Servlet v2.4 pg 65-66)

5. Which calls provide information about initialization parameters that are applicable to an entire web application? (Choose all that apply.)

- A. `ServletConfig.getInitParameters()`  
- B. `ServletContext.getInitParameters()`  
- C. `ServletConfig.getInitParameterNames()`  
- D. `ServletContext.getInitParameterNames()`  
- E. `ServletConfig.getInitParameter(String)`  
- F. `ServletContext.getInitParameter(String)`

(Servlet v2.4 pg 32)

mock answers

Given this code from an otherwise valid `HttpServlet` that has also been registered as a `ServletRequestAttributeListener`:

```java
public void doGet(HttpServletRequest req, HttpServletResponse res)
throws IOException, ServletException {
    req.setAttribute("a", "b");
    req.setAttribute("a", "c");
    req.removeAttribute("a");

    public void attributeAdded(ServletRequestAttributeEvent ev) {
        System.out.print(" A: " + ev.getName() + "-" + ev.getValue());
    }

    public void attributeRemoved(ServletRequestAttributeEvent ev) {
        System.out.print(" M: " + ev.getName() + "-" + ev.getValue());
    }

    public void attributeReplaced(ServletRequestAttributeEvent ev) {
        System.out.print(" P: " + ev.getName() + "-" + ev.getValue());
    }
}
```

What logging output is generated?

- A: a->b P:a->b
- B: a->b M:a->c
- C: a->b P:a->b M:a->c
- D: a->b P:a->b P:a->null

When declaring a listener in the DD, which sub-elements of the `<listener>` element are required? (Choose all that apply.)

- A. `<description>`
- B. `<listener-name>`
- C. `<listener-type>`
- D. `<listener-class>`
- E. `<servlet-mapping>`

The `<listener-class>` sub-element is the ONLY required sub-element of the `<listener>` element.
Which types of objects can store attributes? (Choose all that apply.)

- A. ServletConfig
- B. ServletResponse
- C. RequestDispatcher
- D. HttpServletRequest
- E. HttpSessionContext

Note: The other two types related to servlets, that can store attributes are HttpSession and ServletContext.

Which are true? (Choose all that apply.)

- A. When a web application is preparing to shutdown, the order of listener notification is not guaranteed.
- B. When listener-friendly events occur, listener invocation order is not predictable.
- C. The container registers listeners based on declarations in the deployment descriptor.
- D. Only the container can invalidate a session.

Which statements about RequestDispatcher are true (where applicable, assume the RequestDispatcher was not obtained via a call to getNamedDispatcher()?) (Choose all that apply.)

- A. A RequestDispatcher can be used to forward a request to another servlet.
- B. The only method in the RequestDispatcher interface is forward().
- C. Parameters specified in the query string used to create a RequestDispatcher are not forwarded by the forward() method.
- D. The servlet to which a request is forwarded may access the original query string by calling getQueryParameter() on the ServletRequest.
- E. The servlet to which a request is forwarded may access the original query string by calling getParameter("javax.servlet.forward.query_string") on the ServletRequest.

- Option A and B are incorrect because the container uses the DD to determine the notification order of registered listeners.
- Option D is incorrect because a servlet can invalidate a session using the HttpSession.invalidate() method.
- Option C is incorrect because such parameters are forwarded in this case.
- Option E is invalid because there is no such type.
mock answers

13 Which statements accurately describe how many instances of a servlet the servlet container instantiates for each web application? (Choose all that apply.)

✓ A. If the servlet implements javax.servlet.SingleThreadModel, the container may create one instance for each request.
✓ B. If the servlet does not implement SingleThreadModel, the container may create multiple instances of the servlet in the same JVM.
✓ C. The <load-on-startup> web.xml element can determine how many instances are created.
✓ D. If the servlet does not implement SingleThreadModel, the container will create no more than one instance per JVM.

(Servlet spec p. 24)

14 What is the recommended way to deal with servlets and thread safety?

✓ A. Write the servlet code to extend ThreadSafeServlet.
✓ B. Have the servlet implement SingleThreadModel.
✓ C. Log all servlet method calls.
✓ D. Use local variables exclusively, and if you have to use instance variables, synchronize access to them.

(Servlet spec p. 27)
Web servers have no short-term memory. As soon as they send you a response, they forget who you are. The next time you make a request, they don’t recognize you. In other words, they don’t remember what you’ve requested in the past, and they don’t remember what they’ve sent you in response. Nothing. Sometimes that’s fine. But sometimes you need to keep conversational state with the client across multiple requests. A shopping cart wouldn’t work if the client had to make all his choices and then checkout in a single request. You’ll find a surprisingly simple solution in the Servlet API.
**Objectives**

**Session Management**

4.1 Write servlet code to store objects into a session object and retrieve objects from a session object.

4.2 Given a scenario describe the APIs used to access the session object, explain when the session object was created, and describe the mechanisms used to destroy the session object, and when it was destroyed.

4.3 Using session listeners, write code to respond to an event when an object is added to a session, and write code to respond to an event when a session object migrates from one VM to another.

4.4 Given a scenario, describe which session management mechanism the Web container could employ, how cookies might be used to manage sessions, how URL rewriting might be used to manage sessions, and write servlet code to perform URL rewriting.

**Coverage Notes:**

All four of the exam objectives on session management are covered completely in this chapter (although some of these topics were touched on in the previous chapter). This chapter is your one chance to learn and memorize these topics, so take your time.
Kim wants to keep client-specific state across multiple requests

Right now, the business logic in the model simply checks the parameter from the request and gives back a response (the advice). Nobody in the app remembers anything that went on with this client prior to the current request.

What he has NOW:

```java
public class BeerExpert {
    public ArrayList getBrands(String color) {
        ArrayList brands = new ArrayList();
        if (color.equals("amber")) {
            brands.add("Jack Amber");
        } else {
            brands.add("Red Moose");
            brands.add(" Jail Pale Ale");
            brands.add("Gout Stout");
        }
        return brands;
    }
}
```

What he WANTS:

```java
public class BeerExpert {
    public NextResponse getAdvice(String answer) {
        // Process client answer by looking at
        // ALL of the client’s previous answers, as well
        // as the answer from the current request.
        // if there’s enough info, return final advice,
        // else, return the next question to ask
    }
}
```

The model (the business logic) has to figure out whether it has enough information to make a recommendation (in other words, to give final advice), and if it doesn’t, it has to give back the next question to ask the user.
It's supposed to work like a REAL conversation...

We need some better drinks at this party. I gotta call Kim...

Dude, I'm at Joe's beach party and I am holding in my hand, as I speak, a foamy red umbrella drink...you gotta get some beer over here NOW!

Umbrella drinks? Oooooh, that's just WRONG. Good thing you called...let me ask you some questions—first, do you want something dark, amber, or pale?

Well, I like dark...but this is a wimpy looking crowd, so I'll say amber to be safe.

Hmmm...I have a lot of ambers...do you care about price?

Dude...would I be working as a computer book model if I didn't need the money? OF COURSE I care about price!

No problem...I have some outsourced bitter ale I can send over.
How can he track the client’s answers?

Kim’s design won’t work unless he can keep track of everything the client has already said during the conversation, not just the answer in the current request. He needs the servlet to get the request parameters representing the client’s choices, and save it somewhere. Each time the client answers a question, the advice engine uses all of that client’s previous answers to come up with either another question to ask, or a final recommendation.

What are some options?

Use a stateful session enterprise javabeans

Sure, he could do that. He could have his servlet become a client to a stateful session bean, and each time a request comes in he could locate that client’s stateful bean. There are a lot of little issues to work out, but yes, you can certainly use a stateful session bean to store conversational state.

But that’s way too much overhead (overkill) for this app! Besides, Kim’s hosting provider doesn’t have a full J2EE server with an EJB Container. He’s got Tomcat (a web container) and that’s it.

Use a database

This would work too. His hosting provider does allow access to MySQL, so he could do it. He could write the client’s data to a database... but this is nearly as much of a runtime performance hit as an enterprise bean would be, possibly more. And way more than he needs.

Use an HttpSession

But you already knew that. We can use an HttpSession object to hold the conversational state across multiple requests. In other words, for an entire session with that client.

(Actually, Kim would still have to use an HttpSession even if he did choose another option such as a database or session bean, because if the client is a web browser, Kim still needs to match a specific client with a specific database key or session bean ID, and as you’ll see in this chapter, the HttpSession takes care of that identification.)
sessions in action

How sessions work

1. Diane selects "Dark" and hits the submit button.

   The Container sends the request to a new thread of the BeerApp servlet.

   The BeerApp thread finds the session associated with Diane, and stores her choice ("Dark") in the session as an attribute.

2. The servlet runs its business logic (including calls to the model) and returns a response... in this case another question, "What price range?"

3. Diane considers the new question on the page, selects "Expensive" and hits the submit button.

   The Container sends the request to a new thread of the BeerApp servlet.

   The BeerApp thread finds the session associated with Diane, and stores her new choice ("Expensive") in the session as an attribute.

226  chapter 6
Meanwhile, imagine ANOTHER client goes to the beer site...

Diane's session is still active, but meanwhile Terri selects "Pale" and hits the submit button.

The Container sends Terri’s request to a new thread of the BeerApp servlet.

The BeerApp thread starts a new Session for Terri, and calls setAttribute() to store her choice ("Pale").

We don’t want Terri and Diane’s answers mixed up—so they each need their own separate session object.
recognizing the client

One problem... how does the Container know who the client is?

The HTTP protocol uses stateless connections. The client browser makes a connection to the server, sends the request, gets the response, and closes the connection. In other words, the connection exists for only a single request/response.

Because the connections don’t persist, the Container doesn’t recognize that the client making a second request is the same client from a previous request. As far as the Container’s concerned, each request is from a new client.

Q: Why can’t the Container just use the IP address of the client? It’s part of the request, right?

A: Oh, the Container can get the IP address of the request, but does that uniquely identify the client? If you’re on a local IP network, you have a unique IP address, but chances are, that’s not the IP address the outside world sees. To the server, your IP address is the address of the router, so you have the same IP address as everybody else on that network! So that wouldn’t help. You’d have the same problem—the stuff Jim puts in his shopping cart might end up in Pradeep’s cart, and vice versa. So no, IP address isn’t a solution for uniquely identifying a specific client on the internet.

Q: Well then how about security info? If the user is logged in, and the connection is secure (HTTPS), the Container knows EXACTLY who the client is, right?

A: Yes, if the user is logged in and the connection is secure, the Container can identify the client and associate him with a session. But that’s a big if. Most good web site design says, ‘don’t force the user to log in until it really matters, and don’t switch on security (HTTPS) until it really matters.’ If your users are just browsing, even if they’re adding items to a shopping cart, you probably don’t want the overhead (for you or the user) of having them authenticate to the system until they decide to checkout! So, we need a mechanism to link a client to a session that doesn’t require a securely authenticated client. (We’ll go into security details in the... wait for it... Security chapter.)
The client needs a unique session ID

The idea is simple: on the client’s first request, the Container generates a unique session ID and gives it back to the client with the response. *The client sends back the session ID with each subsequent request.* The Container sees the ID, finds the matching session, and associates the session with the request.

```
Hey server, here’s my first request, with the parameter “dark”. Can we start a conversation?

Yes, but I’m state-challenged and won’t remember you, so I’m giving you a unique session ID. You MUST give that back to me each time you make a request, so I’ll know it’s you.
```

```
Here’s my second request, with the parameter “ale”. My ID# is 42... do you remember me?

Let’s see... #42... oh, there you are! Yes, I remember you now. Last time you said that you liked “dark” bear...
```

---

session management
the joy of Cookies

How do the Client and Container exchange Session ID info?

Somehow, the Container has to get the session ID to the client as part of the response, and the client has to send back the session ID as part of the request. The simplest and most common way to exchange the info is through cookies.

Cookies

Here's your cookie with the session ID inside...

Here's your cookie with the session ID inside...

HTTP/1.1 200 OK

“Cookie” is another header sent in the request.

“Cookie” is another header sent in the request.
The best part: the Container does virtually all the cookie work!

You do have to tell the Container that you want to create or use a session, but the Container takes care of generating the session ID, creating a new Cookie object, stuffing the session ID into the cookie, and setting the cookie as part of the response. And on subsequent requests, the Container gets the session ID from a cookie in the request, matches the session ID with an existing session, and associates that session with the current request.

**Sending a session cookie in the RESPONSE:**

```java
HttpSession session = request.getSession();
```

That’s it. Somewhere in your service method you ask for a session, and everything else happens automatically.

You don’t make the new HttpSession object yourself.
You don’t generate the unique session ID.
You don’t make the new Cookie object.
You don’t associate the session ID with the cookie.
You don’t set the Cookie into the response (under the Set-Cookie header).

All the cookie work happens behind the scenes.

**Getting the session ID from the REQUEST:**

```java
HttpSession session = request.getSession();
```

Look familiar? Yes, it’s exactly the same method used to generate the session ID and cookie for the response!

IF (the request includes a session ID cookie)

find the session matching that ID

ELSE IF (there’s no session ID cookie OR there’s no current session matching the session ID)

create a new session.

All the cookie work happens behind the scenes.
What if I want to know whether the session already existed or was just created?

Good question. The no-arg request method, `getSession()`, returns a session regardless of whether there’s a pre-existing session. Since you always get an `HttpSession` instance back from that method, the only way to know if the session is new is to ask the session.

```java
public void doGet(HttpServletRequest request, HttpServletResponse response)
    throws IOException, ServletException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    out.println("Hello session attributes-
    ");
    HttpSession session = request.getSession();
    if (session.isNew()) {
        out.println("This is a new session.");
    } else {
        out.println("Welcome back!");
    }
}
```

Q: You get a session by calling `request.getSession()`, but is that the only way to get the session? Can’t you get it from the `ServletContext`?

A: You get a session from the request object because—think about it—the session is identified by the request. When you call `getSession()` on the Container you’re saying, “I want a session for THIS client... either the session that matches the session ID this client sent, or a new one. But in either case, the session is for the client associated with this request.”

But there is another way that you can get a session... from a session event object. Remember, a listener class isn’t a servlet or JSP—it’s just a class that wants to know about the events. For example, the listener might be an attribute trying to find out when it (the attribute object) was added to or removed from a session.

The event-handling methods defined by the listener interfaces related to sessions take an argument of type `HttpSessionEvent`, or its subclass, `HttpSessionBindingEvent`. And `HttpSessionEvent` has a `getSession()` method!

So, if you implement any of the four listener interfaces related to sessions (we’ll get to that later in the chapter), you can access the session through the event-handling callback methods. For example, this code is from a class that implements the `HttpSessionListener` interface:

```java
public void sessionCreated(HttpSessionEvent event) {
    HttpSession session = event.getSession();
    // event handling code
}
```
What if I want ONLY a pre-existing session?

You might have a scenario in which a servlet wants to use only a previously-created session. It might not make sense for the checkout servlet, for example, to start a new session.

So there’s an overloaded `getSession(boolean)` method just for that purpose. If you don’t want to create a new session, call `getSession(false)`, and you’ll get either null, or a pre-existing HttpSession.

The code below calls `getSession(false)`, then tests whether the return value was null. If it was null, the code outputs a message and then creates a new session.

```java
public void doGet(HttpServletRequest request, HttpServletResponse response) throws IOException, ServletException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    HttpSession session = request.getSession(false);
    if (session==null) {
        out.println("no session was available");
        session = request.getSession();
    } else {
        out.println("there was a session!");
    }
}
```

Q: Isn’t the code above just a stupid, inefficient way to do the same thing as the opposite page? In the end, you still created a new session.

A: You’re right. The code above is just for testing how the two different versions of `getSession()` work. In the real world, the only time you’d want to use `getSession(false)` is if you DO NOT want to create a new session. If your goal is to create a new session, but still respond differently if you know this is a new (versus pre-existing) session, then use the no-arg `getSession()` method, and simply ask the session if it’s new using the HttpSession isNew() method.

Q: So it looks like `getSession(true)` is exactly the same as `getSession()`...

A: Right again. The no-arg version is a convenience for those times when you know that you always want a session, new or existing. The version that takes a boolean is useful when you know that you don’t want a new session, or when the decision of whether to make a new session happens at runtime (and you’re passing a variable into the `getSession(someBoolean)` method).
You can do sessions even if the client doesn’t accept cookies, but you have to do a little more work...

We don’t agree that anybody with half a brain disables cookies. In fact, most browsers do have cookies enabled, and everything’s wonderful. But there’s no guarantee.

If your app depends on sessions, you need a different way for the client and Container to exchange session ID info. Lucky for you, the Container can handle a cookie-refusing client, but it takes a little more effort from you.

If you use the session code on the previous pages—calling getSession() on the request—the Container tries to use cookies. If cookies aren’t enabled, it means the client will never join the session. In other words, the session.isNew() method will always return true.
URL rewriting: something to fall back on

If the client won’t take cookies, you can use URL rewriting as a back-up. Assuming you do your part correctly, URL rewriting will always work—the client won’t care that it’s happening and won’t do anything to prevent it. Remember the goal is for the client and Container to exchange session ID info. Passing cookies back and forth is the simplest way to exchange session IDs, but if you can’t put the ID in a cookie, where can you put it? URL rewriting takes the session ID that’s in the cookie and sticks it right onto the end of every URL that comes in to this app.

Imagine a web page where every link has a little bit of extra info (the session ID) tacked onto the end of the URL. When the user clicks that “enhanced” link, the request goes to the Container with that extra bit on the end, and the Container simply strips off the extra part of the request URL and uses it to find the matching session.

We add the session ID to the end of all the URLs in the HTML we send back in the Response.

The session ID comes back as “extra” info stuck to the end of the Request URL. (The semicolon separator is vendor-specific.)
URL rewriting

URL rewriting kicks in only if cookies fail, and only if you tell the response to encode the URL

If cookies don’t work, the Container falls back to URL rewriting, but only if you’ve done the extra work of encoding all the URLs you send in the response. If you want the Container to always default to using cookies first, with URL rewriting only as a last resort, you can relax. That’s exactly how it works (except for the first time, but we’ll get to that in a moment). But if you don’t explicitly encode your URLs, and the client won’t accept cookies, you don’t get to use sessions. If you do encode your URLs, the Container will first attempt to use cookies for session management, and fall back to URL rewriting only if the cookie approach fails.

public void doGet(HttpServletRequest request, HttpServletResponse response)
throws IOException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    HttpSession session = request.getSession();
    out.println("<html><body>");
    out.println("<a href=" + response.encodeURL("/BeerTest.do") + ">
" + click me<a/"/>
    out.println("</body></html>";)
}

Q: Wait a minute... how does the Container know that cookies aren’t working? At what point does the Container decide to use URL rewriting?

A: A really dumb Container doesn’t care whether cookies work or not—the dumb Container will always attempt to send the cookie AND do URL rewriting each time, even if cookies are working. But here’s how a decent Container handles it:

When the Container sees a call to getSession(), and the Container didn’t get a session ID with the client’s request, the Container now knows that it must attempt to start a new session with the client. At this point, the Container doesn’t know if cookies will work, so with this first response back to the client, it tries BOTH cookies and URL rewriting.

Q: Why can’t it try cookies first... and do URL rewriting on the next response if it doesn’t get back a cookie?

A: Remember, if the Container doesn’t get a session ID from the client, the Container won’t even KNOW that this is the next request from that client. The Container won’t have any way to know that it tried cookies the last time, and they didn’t work. Remember, the only way the Container can recognize that it has seen this client before is if the client sends a session ID!

So, when the Container sees you call request.getSession(), and realizes it needs to start a new session with this client, the Container sends the response with both a “Set-Cookie” header for the session ID, and the session ID appended to the URLs (assuming you used response.encodeURL()).

Now imagine the next request from this client—it will have the session ID appended to the request URL, but if the client accepts cookies, the request will ALSO have a session ID cookie. When the servlet calls request.getSession(), the Container reads the session ID from the request, finds the session, and thinks to itself, “This client accepts cookies, so I can ignore the response.encodeURL() calls. In the response, I’ll send a cookie since I know that works, and there’s no need for any URL rewriting, so I won’t bother...”
URL rewriting works with sendRedirect() 

You might have a scenario in which you want to redirect the request to a different URL, but you still want to use a session. There’s a special URL encoding method just for that:

```java
response.encodeRedirectURL("/BeerTest.do")
```

**Q:** What about all my static HTML pages... they are full of `<a href=...>` links. How do I do URL rewriting on those static pages?

**A:** You can’t! The only way to use URL rewriting is if ALL the pages that are part of a session are dynamically-generated! You can’t hard-code session ID’s, obviously, since the ID doesn’t exist until runtime. So, if you depend on sessions, you need URL rewriting as a fall-back strategy. And since you need URL rewriting, you have to dynamically generate the URLs in the response HTML! And that means you have to process the HTML at runtime.

Yes, this is a performance issue. So you must think very carefully about the places where sessions matter to your app, and whether sessions are critical to have or merely good to have.

**Q:** You said that to use URL rewriting, pages must be dynamically-generated, so does this mean I can do it with JSPs?

**A:** Yes! You can do URL rewriting in a JSP, and there’s even a simple JSTL tag that makes it easy, `<c:url>` that you’ll see when you get to the chapter on using custom tags.

**Q:** Is URL rewriting handled in a vendor-specific way?

**A:** Yes, URL rewriting is handled in a vendor-specific way. Tomcat uses a semicolon `;` to append the extra info to the URL. Another vendor might use a comma or something else. And while Tomcat adds `"sessionid="` in the rewritten URL, another vendor might append only the session ID itself. The point is, whatever the Container uses as the separator is recognized by the Container when a request comes in. So when the Container sees the separator that it uses (in other words, the separator that it added during URL rewriting), it knows that everything after that is "extra info" that the Container put there. In other words, the Container knows how to recognize and parse the extra stuff it (the Container) appended to the URL.

**URL encoding is handled by the Response!**

Don’t forget that the `encodeURL()` method is something you call on your `HttpServletResponse` object! You don’t call it on the request, or on your context, or your session object. Just remind yourself that URL encoding is all about the response.

You are here → 237
**session management**

Don't be fooled by a request parameter "sessionsid" or a "JSESSIONID" header.

You don't ever use "sessionsid" yourself. If you see a "sessionsid" request parameter, somebody's doing something wrong. You should never see something like this:

```java
String sessionID = request.getParameter("sessionsid")
```

And you shouldn't see a custom "sessionsid" header in a request or response:

```http
POST /select/selectBeerTaste.do HTTP/1.1
User-Agent: Mozilla/5.0
SESSIONID: 0AAB6C8DE415
```

In fact, the ONLY place a "sessionsid" belongs is inside a cookie header:

```http
POST /select/selectBeerTaste.do HTTP/1.1
User-Agent: Mozilla/5.0
Cookie: JSESSIONID=0AAB6C8DE415
```

or appended to the end of a URL as 'extra info':

```http
POST /select/selectBeerTaste.do?sessionId=0AAB6C8DE415
```

**BULLET POINTS**

- URL rewriting adds the session ID to the end of all the URLs in the HTML that you write to the response.

- The session ID then comes back with the request as 'extra' info at the end of the request URL.

- URL rewriting will happen automatically if cookies don't work with the client, but you have to explicitly encode all of the URLs you write.

- To encode a URL, call `response.encodeURL(sString)`,
  ```java
  out.println("<a href=" +
             response.encodeURL("/BeerTest.do") +
  ");
  ```

- There's no way to get automatic URL rewriting with your static pages, so if you depend on sessions, you must use dynamically-generated pages.

Getting rid of sessions

The client comes in, starts a session, then changes her mind and leaves the site. Or the client comes in, starts a session, then her browser crashes. Or the client comes in, starts a session, and then completes the session by making a purchase (shopping cart check-out). Or her computer crashes. Whatever.

The point is, session objects take resources. You don’t want sessions to stick around longer than necessary. Remember, the HTTP protocol doesn’t have any mechanism for the server to know that the client is gone. (In distributed application terms, for those of you familiar with them—there’s no leasing!)

But how does the Container (or you) know when the client walked away? How does the Container know when the client’s browser crashed? How does the Container know when it’s safe to destroy a session?

FLEX YOUR MIND

What are strategies you (and the Container) might use to manage the number of sessions, and eliminate unneeded sessions? What are some possible ways in which the Container could tell that a session is no longer needed?

Think about it, then look at the HttpSession API a few pages from now for clues.

*Some distributed apps use leasing as a way for the server to know when a client is gone. The client gets a lease from the server, and then must renew the lease at specified intervals to tell the server that the client is still alive. If the client’s lease expires, the server knows it can destroy any resources it was holding for that client.
How we want it to work...

We’d like the Container to recognize when a session has been inactive for too long, and destroy the session. Of course we might have to fight the Container over what “too long” really means. Is 20 minutes too long? An hour? A day? (Maybe there’s a way for us to tell the Container what “too long” is.)

1. Diane selects “Dark” and hits the submit button.

2. Diane vanishes, mysteriously.

3. Diane doesn’t return. Minutes go by...

...the session

...the session ends

...the session ends
The HttpSession interface

All you care about when you call getSession() is that you get an instance of a class that implements the HttpSession interface. It’s the Container’s job to create the implementation.

Once you have a session, what can you do with it?

Most of the time, you’ll use sessions to get and set session-scoped attributes.

But there’s more, of course. See if you can figure out some of the key methods for yourself (answers are on the next page, so don’t turn the page!)

Sharpen your pencil

<table>
<thead>
<tr>
<th>What it does</th>
<th>What you’d use it for</th>
</tr>
</thead>
<tbody>
<tr>

</table>

...
HttpSession methods

Key HttpSession methods

You already know about the methods for attributes (getAttribute(), setAttribute(), removeAttribute()), but here are a few key ones you might need in your application (and that might be on the exam).

<table>
<thead>
<tr>
<th>Method</th>
<th>What it does</th>
<th>What you’d use it for</th>
</tr>
</thead>
<tbody>
<tr>
<td>getCreationTime()</td>
<td>Returns the time the session was first created</td>
<td>To find out how old the session is. You might want to restrict certain sessions to a fixed length of time. For example, you might say, “Once you’ve logged in, you have exactly 10 minutes to complete this form…”</td>
</tr>
<tr>
<td>getLastAccessedTime()</td>
<td>Returns the last time the Container got a request with this session ID (in milliseconds).</td>
<td>To find out when a client last accessed this session. You might use it to decide that if the client’s been gone a long time you’ll send them an email asking if they’re coming back. Or maybe you’ll invalidate() the session.</td>
</tr>
<tr>
<td>setMaxInactiveInterval()</td>
<td>Specifies the maximum time, in seconds, that you want to allow between client requests for this session.</td>
<td>To cause a session to be destroyed after a certain amount of time has passed without the client making any requests for this session. This is one way to reduce the amount of stale sessions sitting in your server.</td>
</tr>
<tr>
<td>getMaxInactiveInterval()</td>
<td>Returns the maximum time, in seconds, that is allowed between client requests for this session.</td>
<td>To find out how long this session can be inactive and still be alive. You could use this to judge how much more time an inactive client has before the session will be invalidated.</td>
</tr>
<tr>
<td>invalidate()</td>
<td>Ends the session. This includes unbinding all session attributes currently stored in this session. (More on that later in this chapter.)</td>
<td>To kill a session if the client has been inactive or if you KNOW the session is over (for example, after the client does a shopping check-out or log). The session instance itself might be recycled by the Container, but we don’t care. Invalidate means the session ID no longer exists, and the attributes are removed from the session object.</td>
</tr>
</tbody>
</table>

FLEX YOUR MIND

Now that you’ve seen these methods, can you put together a strategy for eliminating abandoned sessions?
Setting session timeout

Good news: you don’t have to keep track of this yourself. See those methods on the opposite page? You don’t have to use them to get rid of stale (inactive) sessions. The Container can do it for you.

Three ways a session can die:

➤ It times out
➤ You call invalidate() on the session object
➤ The application goes down (crashes or is undeployed)

Configuring session timeout in the DD

Configuring a timeout in the DD has virtually the same effect as callingsetMaxInactiveInterval() on every session that’s created.

    <web-app ...>
    <servlet>
    ... 
    </servlet>
    <session-config>
        <session-timeout>15</session-timeout>
    </session-config>
    </web-app>

Setting session timeout for a specific session

If you want to change the session-timeout value for a particular session instance (without affecting the timeout length for any other sessions in the app):

    session.setMaxInactiveInterval(20*60);

Here’s a big inconsistency to watch out for... you specify timeouts in the DD using MINUTES, but if you set a timeout programmatically, you specify SECONDS!

You can’t be serious... does this mean that I have to keep track of session activity and that I have to destroy the stale sessions? Can’t the Container do that?
**Code Magnets**

Specify in both the DD, and programmatically, that if a session does not receive any requests for 20 minutes, it should be destroyed. We put one magnet in the servlet for you, to get started, and you might not use all magnets.

```java
public void doGet(HttpServletRequest request, HttpServletResponse response) throws IOException {

    // DD

    HttpSession session = request.getSession();
    session.setAttribute("session-active", true);
    session.setAttribute("session-timeout", 12000);
    session.setAttribute("session-context", "context-config");

    // Servlet

    session.setAttribute("session-context", "context-config");
    session.setAttribute("session-timeout", 12000);
    session.setAttribute("session-context", "context-config");
}```
Each of the two listings represents code from a compiled littleServlet. Your job is to think like the Container and determine what will happen when each of these servlets are invoked twice by the same client. Describe what happens the first and second time the same client accesses the servlet.

```java
public void doGet(HttpServletRequest request, HttpServletResponse response) throws IOException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    HttpSession session = request.getSession();
    session.setAttribute("foo", "42");
    session.setAttribute("bar", "420");
    session.invalidate();
    String foo = (String) session.getAttribute("foo");
    out.println("Foo: " + foo);
}
```

```java
public void doGet(HttpServletRequest request, HttpServletResponse response) throws IOException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    HttpSession session = request.getSession();
    session.setAttribute("foo", "42");
    session.setMaxInactiveInterval(0);
    String foo = (String) session.getAttribute("foo");
    if (session.isNew()) {
        out.println("This is a new session.");
    } else {
        out.println("Welcome back!");
    }

    out.println("Foo: " + foo);
}
```
**exercise answers**

---

**Code Magnets Answers**

**- DD**

```xml
<web-app ...>
  <session-config>
    <session-timeout>20</session-timeout>
  </session-config>
</web-app>
```

Remember, the timeout in the DD is specified in MINUTES.

**- Servlet**

```java
public void doGet(HttpServletRequest request, HttpServletResponse response)
  throws IOException {
    HttpSession session = request.getSession();
    session.setMaxInactiveInterval(1200); // In code, the timeout is specified in SECONDS.
    setCreationTime(12000); // It is unnecessary to set the creation time.
    request.getSession().setSessionTimeout(20); // It is unnecessary to set the session timeout.
}
```
public void doGet(HttpServletRequest request, HttpServletResponse response) throws IOException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    HttpSession session = request.getSession();
    session.setAttribute("foo", "42");
    session.invalidate(); // here we invalidate the session
    String foo = (String)session.getAttribute("foo");
    out.println("Foo: " + foo);
}

Result: a runtime exception (IllegalArgumentException) is thrown because you can't get an attribute AFTER the session becomes invalid.

public void doGet(HttpServletRequest request, HttpServletResponse response) throws IOException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    HttpSession session = request.getSession();
    session.setAttribute("foo", "42");
    session.setMaxInactiveInterval(0);
    if (session.isNew()) {
        out.println("This is a new session.");
    } else {
        out.println("Welcome back!");
    }
    out.println("Foo: " + session.getAttribute("foo"));
}

Result: a runtime exception (IllegalArgumentException) is thrown because you can't call isNew() on the session AFTER the session becomes invalid. Setting the maximum inactive interval to 0 means the session times out and is invalidated immediately! 
Custom cookies

Can I use cookies for other things, or are they only for sessions?

Although cookies were originally designed to help support session state, you can use custom cookies for other things. Remember, a cookie is nothing more than a little piece of data (a name/value string pair) exchanged between the client and server. The server sends the cookie to the client, and the client returns the cookie when the client makes another request.

One cool thing about cookies is that the user doesn’t have to get involved—the cookie exchange is automatic (assuming cookies are enabled on the client, of course).

By default, a cookie lives only as long as a session; once the client quits his browser, the cookie disappears. That’s how the “SESSIONID” cookie works. But you can tell a cookie to stay alive even AFTER the browser shuts down.

That way, your web app can still get the cookie information even though the session with that client is long gone. Imagine that Kim wants to display the user’s name each time he returns to the beer site. So he sets the cookie the first time he receives the client’s name, and if he gets the cookie back with a request, he knows not to ask for the name again. And it doesn’t matter if the user restarted his browser and hasn’t been on the site for a week!

HTTP/1.1 200 OK
Set-Cookie: username=TomasHirsch
        expires=Thu, 31 Mar 2005 22:45:30 GMT
        domain=.example.com
        path=pathToMyJavaApp;

POST /projects/selectUser.action HTTP/1.1
host: www.myservlet.com
User-Agent: Mozilla/5.0
Cookie: username=TomasHirsch

Server sends this first

Client sends this back

You can use cookies to exchange name/value string pairs between the server and the client. The server sends the cookie to the client, and the client sends it back with each subsequent request.

Session cookies vanish when the client’s browser quits, but you CAN tell a cookie to persist on the client even after the browser shuts down.

Chapter 6. Conversational state
**Using Cookies with the Servlet API**

You can get cookie-related headers out of the HTTP request and response, but don’t. Everything you need to do with cookies has been encapsulated in the Servlet API in three classes: HttpServletRequest, HttpServletResponse, and Cookie.

Creating a new Cookie

```java
Cookie cookie = new Cookie("username", name);
```

Setting how long a cookie will live on the client

```java
cookie.setMaxAge(30*60);
```

Sending the cookie to the client

```java
response.addCookie(cookie);
```

Getting the cookie(s) from the client request

```java
Cookie[] cookies = request.getCookies();
for (int i = 0; i < cookies.length; i++) {
    Cookie cookie = cookies[i];
    if (cookie.getName().equals("username")) {
        String username = cookie.getValue();
        out.println("Hello "+ username);
        break;
    }
}
```
**Simple custom cookie example**

So, imagine that Kim wants to put up a form that asks the user to submit his name. The form calls a servlet that gets the username request parameter, and uses the name value to set a cookie in the response.

The next time this user makes a request on ANY servlet in this web app, the cookie comes back with the request (assuming the cookie is still alive, based on the cookie's maxAge value). When a servlet in the web app sees this cookie, it can put the user's name into the dynamically-generated response, and the business logic knows not to ask the user to input his name again.

This code is a simplified test version of the scenario we just described.

**Servlet that creates and SETS the cookie**

```java
import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;

public class CookieTest extends HttpServlet {
    public void doPost(HttpServletRequest request, HttpServletResponse response)
        throws IOException, ServletException {

        String name = request.getParameter("username");
        Cookie cookie = new Cookie("username", name);
        cookie.setMaxAge(30*60);
        response.addCookie(cookie);

        RequestDispatcher view = request.getRequestDispatcher("cookieResult.jsp");
        view.forward(request, response);
    }
}
```

**JSP to render the view from this servlet**

```html
<html><body>
<a href="checkcookie.do">click here</a>
</body></html>
```

250 chapter 6
Custom cookie example continued...

Servlet that GETS the cookie

import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;

public class CheckCookie extends HttpServlet {
    public void doGet(HttpServletRequest request, HttpServletResponse response)
        throws IOException, ServletException {
            response.setContentType("text/html");
            PrintWriter out = response.getWriter();
            Cookie[] cookies = request.getCookies();
            for (int i = 0; i < cookies.length; i++) {
                Cookie cookie = cookies[i];
                if (cookie.getName().equals("username")) {
                    String userName = cookie.getValue();
                    out.println("Hello "+ userName);
                    break;
                }
            }
        }

You don’t have to know ALL the Cookie methods.
For the exam, you don’t have to remember every one of the methods
in class Cookie, but you must know the request and response
methods to get and add Cookies. You should also know the Cookie
constructor and the get and set methods.

Don’t confuse Cookies
with headers!
When you add a header to a response, you pass the name
and value Strings as arguments:
response.addHeader("foo", "bar");
But when you add a Cookie to the response, you pass a
Cookie object. You set the Cookie name and value in the
Cookie constructor:
Cookie cookie = new Cookie("name", value);
response.addCookie(cookie);
And remember, too, that there’s both a setHeader() and
an addHeader() method (addHeader adds a new value to
an existing header, if there is one, but setHeader replaces
the existing value). But there’s NOT a setCookie() method.
There’s only an addCookie() method.

session lifecycle moments

Key milestones for an HttpSession

Highlights of the important moments in an HttpSession object’s life:

The session is created or destroyed.

Session attributes are added, removed, or replaced by other parts of the app.

The session is passivated in one VM and activated in another within a distributed app.
### Session lifecycle Events

<table>

**HttpSessionBindingListener**

**Don’t forget about HttpSessionBindingListener**

The events on the previous page are for key moments in the life of the session. But the HttpSessionBindingListener is for key moments in the life of a session attribute. Remember from chapter 5 where we looked at how you might use this—if, for example, your attribute wants to know when it’s added to a session so that it can synchronize itself with an underlying database (and update the database when it’s removed from a session). Here’s a little review from the previous chapter:

```java
package com.example;
import javax.servlet.http.*;

public class Dog implements HttpSessionBindingListener
{
    private String breed;
    public Dog(String breed) {
        this.breed = breed;
    }
    public String getBreed() {
        return breed;
    }
    public void valueBound(HttpSessionBindingEvent event) {
        // code to run now that I know I’m in a session
    }
    public void valueUnbound(HttpSessionBindingEvent event) {
        // code to run now that I know I no longer part of a session
    }
}
```

This listener is in the `javax.servlet.http` Package.

The word “Bound” means someone ADDED this attribute to a session.

The word “Unbound” means you can figure out what “Unbound” means.

**You do NOT configure session binding listeners in the DD!**

If an attribute class (like the Dog class here) implements the HttpSessionBindingListener, the Container calls the event-handling callbacks (valueBound() and valueUnbound()) when an instance of this class is added to or removed from a session. That’s it. It just works. But this is NOT true for the other session-related listeners on the previous page, HttpSessionListener, HttpSessionAttributeListener, and HttpSessionActivationListener, the Session must be registered in the DD, since they’re related to the session itself, rather than an individual attribute placed in the session.
Session migration

Remember from the previous chapter, we talked briefly about distributed web apps, where the pieces of the app might be replicated across multiple nodes in the network. In a clustered environment, the Container might do load-balancing by taking client requests and sending them out to JVMs (which may or may not be on different physical boxes, but that doesn’t matter to us). The point is, the app is in multiple places.

That means each time the same client makes a request, the request could end up going to a different instance of the same servlet. In other words, request A for Servlet A could happen on one VM, and request B for Servlet A could end up on a different VM. So the question is, what happens to things like ServletContext, ServletConfig, and HttpSession objects?

Simple answer, important implications:

*Only HttpSession objects (and their attributes) move from one VM to another.*

There is one ServletContext per VM. There is one ServletConfig per servlet per VM. But there is only one HttpSession object for a given session ID per web app, regardless of how many VMs the app is distributed across.

### The Beer Web App distributed across two VMs

- Each servlet has its own ServletConfig, and both servlets in the web app share a ServletContext.
- Everything except the HttpSession is duplicated on the other VM.

- Note: everything is duplicated in the second server EXCEPT the HttpSession objects!
- Sessions live in only ONE place at any given moment. The same session ID for a given web app will NEVER appear in two VMs at the same time.
**Session migration in action**

How an app server vendor handles clustering and web app distribution varies with each vendor, and there's no guarantee in the J2EE spec that a vendor has to support distributed apps. But the picture here gives you a high-level idea of how it works. The key point is that while other parts of the app are replicated on each node/VM, the session objects are moved. And that is guaranteed. In other words, if the vendor does support distributed apps, then the Container is required to migrate sessions across VMs. And that includes migrating session attributes as well.

Diane selects "Pale" and hits the submit button.

The Load-Balancing server decides to send the request to Container A-1 in VM One.

The Container makes a new session, ID 343. The "JSESSIONID" cookie is sent back to Diane in the response (not shown).

Diane selects "Bitter" and hits the submit button. Her request also includes the "JSESSIONID" #343.

This time, the Load-Balancing server decides to send the request to Container A-2 in VM Two.

The Container gets the request, sees the session ID, and realizes that the session is on a different VM, VM One!

Uh-oh, her session is on VM One. That #343 session must migrate over here.
The session #343 migrates from VM One to VM Two. In other words, it no longer exists on VM One once it moves to VM Two. This migration means the session was passivated on VM One, and activated on VM Two.

The Container makes a new thread for ServletA, and associates the new request with the recently moved session #343. Diane’s new request is sent to the thread, and everybody is happy. Diane has no idea what happened (except for the slight delay/lag waiting for the session to move).
HttpSessionActivationListener

HttpSessionActivationListener lets attributes prepare for the big move...

Since it’s possible that an HttpSession can migrate from one VM to another, the spec designers thought it would be nice if someone bothered to tell the attributes within the session that they too, were about to move. That way the attributes can make sure they’ll survive the trip.

If all your attributes are straightforward Serializable objects that don’t care where they end up, you’ll probably never use this listener. In fact, we’re guessing 95.324% of all web apps never use this listener. But it’s there if you need it, and the most likely use of this listener is to give attributes a chance to make their instance variables ready for Serialization.

Session migration and Serialization

Now it gets a little tricky...

A Container is required to migrate Serializable attributes (which assumes that all instance variables within the attribute are either Serializable or null).

But a Container is not required to use Serialization as the means for migrating the HttpSession object!

What does this mean to you? Simple: make sure your attribute class types are Serializable and you never have to worry about it. But if they’re not Serializable (which could be because one of the attribute object’s instance variables is not Serializable), have your attribute object class implement HttpSessionActivationListener and use the activation/passivation callbacks to work around it.

This listener is so that as an attribute, I can find out when I’m about to be moved to a new VM as part of a session, and I can make sure my instance variables are ready...

The Container is not REQUIRED to use Serialization, so there’s no guarantee that readObject() and writeObject() will be called on a Serializable attribute or one of its instance variables!

If you’re familiar with Serialization, you know that a class that implements Serializable can also choose to implement a readObject() method, called by the VM whenever an object is deserialized, and a writeObject() method, called when an object is serialized. A Serializable object can use these methods to, for example, set non-Serializable fields to null during Serialization (writeObject()) and then restore the fields during deserialization (readObject()). (If you’re NOT familiar with the details of Serialization, don’t worry about it.)

But the methods won’t necessarily be called during session migration! So if you need to save and restore instance variable state in your attribute, use HttpSessionActivationListener, and use the two event callbacks (sessionDidActivate() and sessionWillPassivate()) the way you’d use readObject() and writeObject().
Listener examples

Over the next three pages, pay attention to the event object types and to whether the listener is also an attribute class.

Session counter

This listener lets you keep track of the number of active sessions in this web app. Very simple.

```java
package com.example;
import javax.servlet.http.*;

public class BeerSessionCounter implements HttpSessionListener {
    static private int activeSessions;
    public static int getActiveSessions() { return activeSessions; }

    public void sessionCreated(HttpSessionEvent event) {
        activeSessions++;
    }

    public void sessionDestroyed(HttpSessionEvent event) {
        activeSessions--;
    }
}
```

Configuring the listener in the DD

```xml
<web-app ...>
...
    <listener>
        <listener-class>
            com.example.BeerSessionCounter
        </listener-class>
    </listener>
</web-app>
```
session attribute listener

Listener examples

Attribute Listener
This listener lets you track each time any attribute is added to, removed from, or replaced in a session.

```java
package com.example;
import javax.servlet.http.*;

public class BeerAttributeListener implements HttpSessionAttributeListener {
    public void attributeAdded(HttpSessionBindingEvent event) {
        String name = event.getName();
        Object value = event.getValue();
        System.out.println("Attribute added: "+ name + ": " + value);
    }

    public void attributeRemoved(HttpSessionBindingEvent event) {
        String name = event.getName();
        Object value = event.getValue();
        System.out.println("Attribute removed: "+ name + ": " + value);
    }

    public void attributeReplaced(HttpSessionBindingEvent event) {
        String name = event.getName();
        Object value = event.getValue();
        System.out.println("Attribute replaced: "+ name + ": " + value);
    }
}
```

Configuring the listener in the DD

```xml
<web-app ...>
    ...
    <listener>
        <listener-class>com.example.BeerAttributeListener</listener-class>
    </listener>
</web-app>
```

Q: Hey, what the heck are you printing to? Where does System.out go in a web app?

A: Wherever this Container chooses to send it (which may or may not be configurable by you). In other words, in a vendor-specific place, often a log file. Tomcat puts the output in tomcat/logs/catalina.log. You’ll have to read your server docs to find out what your Container does with standard output.
Listener examples

Attribute class (listening for events that affect it)

This listener lets an attribute keep track of events that might be important to the attribute itself—when it’s added to or removed from a session, and when the session migrates from one VM to another.

```java
package com.example;
import javax.servlet.http.*;
import java.io.*;

public class Dog implements HttpSessionBindingListener,
HttpSessionActivationListener, Serializable {
    private String breed;
    // imagine more instance variables, including
    // some that are not Serializable
    // imagine constructor and other getter/setter methods

    public void valueBound(HttpSessionBindingEvent event) {
        // code to run now that I know I'm in a session
    }

    public void valueUnbound(HttpSessionBindingEvent event) {
        // code to run now that I am no longer part of a session
    }

    public void sessionWillPassivate(HttpSessionEvent event) {
        // code to get my non-Serializable fields in a state
        // that can survive the move to a new VM
    }

    public void sessionDidActivate(HttpSessionEvent event) {
        // code to restore my fields... to redo whatever I undid
        // in sessionWillPassivate()
    }
}
```

Configuring the listener in the DD

```xml
<web-app ...>
    <listener>
        <listener-class>
            com.example.Dog
        </listener-class>
    </listener>
</web-app>
```

This Dog class must be configured in the DD, but ONLY because it is a session activation listener! If it implemented only the HttpSessionBindingListener interface, it would NOT be configured in the DD, and the Container would simply take care of notifying it. But an HttpSessionActivationListener need not be an attribute class (although that’s its most typical use).
**Session-related Listeners**

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Listener interface/methods</th>
<th>Event type</th>
<th>Usually implemented by</th>
</tr>
</thead>
<tbody>
<tr>
<td>You want to know how many concurrent users there are. In other words, you want to track the active sessions.</td>
<td>HttpSessionListener (javax.servlet.http) sessionCreated sessionDestroyed</td>
<td>HttpSessionEvent</td>
<td>An attribute class</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Some other class</td>
</tr>
<tr>
<td>You want to know when a session moves from one VM to another.</td>
<td>HttpSessionActivationListener (javax.servlet.http) sessionDeActivate sessionWillPassivate</td>
<td>HttpSessionEvent</td>
<td>An attribute class</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Some other class</td>
</tr>
<tr>
<td>You have an attribute class (a class for an object that will be used as an attribute value) and you want objects of this type to be notified when they are bound to or removed from a session.</td>
<td>HttpSessionBindingListener (javax.servlet.http) valueBound valueUnbound</td>
<td>HttpSessionBindingEvent</td>
<td>An attribute class</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Some other class</td>
</tr>
<tr>
<td>You want to know when any session attribute is added, removed, or replaced in a session.</td>
<td>HttpSessionAttributeListener (javax.servlet.http) attributeAdded attributeRemoved attributeReplaced</td>
<td>HttpSessionEvent</td>
<td>An attribute class</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Some other class</td>
</tr>
</tbody>
</table>

Note: there's no specific HttpSessionActivationEvent.

Note: there's no specific HttpSessionAttributeEvent.
The `getName()` method returns the String name of the attribute that triggered the event.

The `getValue()` method returns the Object value of the attribute that triggered the event. Watch out! It returns the old value, not the new one. In other words, it returns the value the attribute had BEFORE the change that triggered the event!
### Session-related Listeners

Yes, this is almost an exact copy of the table from two pages back, so don’t go there. Try to think through these listeners and put down your best guess. You can expect at least two, and as many as four questions on the exam about session listeners. Use both your memory and common sense to fill this out.

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Listener interface/methods</th>
<th>Event type</th>
<th>Usually implemented by</th>
</tr>
</thead>
<tbody>
<tr>
<td>You want to know when a session is created.</td>

264 chapter 6
Given:

10. public class MyServlet extends HttpServlet {
11.     public void doGet(HttpServletRequest req, 
            HttpServletResponse res) 
12.         throws IOException, ServletException {
13.         // request.getSession().setAttribute("key", "value");
14.         // request.getSession().setAttribute("key", "value");
15.         // ((HttpSession)request.getSession()).setAttribute("key", "value");
16.         // ((HttpSession)request.getSession()).setAttribute("key", "value");
17.     }
18. }

Which line(s) could be uncommented without causing a compile or runtime error?
(Choose all that apply.)

- A. Line 15 only.
- B. Line 14 only.
- C. Line 15 only.
- D. Line 16 only.
- E. Line 13 or line 15.
- F. Line 14 or line 16.

If a client will NOT accept a cookie, which session management mechanism could the web container employ? (Choose one.)

- A. Cookies, but NOT URL rewriting.
- B. URL rewriting, but NOT cookies.
- C. Either cookies or URL rewriting can be used.
- D. Neither cookies nor URL rewriting can be used.
- E. Cookies and URL rewriting must be used together.
mock exam

3. Which statements about HttpSession objects are true? (Choose all that apply.)
   - A. A session whose timeout period has been set to -1 will never expire.
   - B. A session will become invalid as soon as the user closes all browser windows.
   - C. A session will become invalid after a timeout period defined by the servlet container.
   - D. A session may be explicitly invalidated by calling HttpSession.invalidateSession().

4. Which of the following are NOT listener event types in the J2EE 1.4 API? (Choose all that apply.)
   - A. HttpSessionEvent
   - B. ServletRequestEvent
   - C. HttpSessionBindingEvent
   - D. HttpSessionAttributeEvent
   - E. ServletContextAttributeEvent

5. Which statements about session tracking are true? (Choose all that apply.)
   - A. URL rewriting may be used by a server as the basis for session tracking.
   - B. SSL has a built-in mechanism that a servlet container could use to obtain data used to define a session.
   - C. When using cookies for session tracking, there is no restriction on the name of the session tracking cookie.
   - D. When using cookies for session tracking, the name of the session tracking cookie must be JSESSIONID.
   - E. If a user has cookies disabled in their browser, the container may choose to use a javax.servlet.http.CookielessHttpSession object to track the user’s session.
session management

6. Given:

```java
6. import javax.servlet.http.*;
2. public class MySessionListener
    implements HttpSessionListener {
3.     public void sessionCreated() {
4.         System.out.println("Session Created");
5.     }
6.     public void sessionDestroyed() {
7.         System.out.println("Session Destroyed");
8.     }
9. }
```

What is wrong with this class? (Choose all that apply.)

- A. The method signature on line 3 is NOT correct.
- B. The method signature on line 6 is NOT correct.
- C. The import statement will NOT import the HttpSessionListener interface.
- D. sessionCreated and sessionDestroyed are NOT the only methods defined by the HttpSessionListener interface.

7. Which statements about session attributes are true? (Choose all that apply.)

- A. The return type of HttpSession.getAttribute(String) is Object.
- B. The return type of HttpSession.getAttribute(String) is String.
- C. Attributes bound into a session are available to any other servlet that belongs to the same ServletContext.
- D. Calling setAttribute("keyA", "valueB") on an HttpSession which already holds a value for the key keyA will cause an exception to be thrown.
- E. Calling setAttribute("keyA", "valueB") on an HttpSession which already holds a value for the key keyA will cause the previous value for this attribute to be replaced with the String valueB.

you are here  267
mock exam

8 Which interfaces define a `getSession()` method? (Choose all that apply.)

- A. `ServletRequest`
- B. `ServletResponse`
- C. `HttpServletRequest`
- D. `HttpServletResponse`

9 Given a session object `s`, and the code:

```java
s.setAttribute("key", value);
```

Which listeners could be notified? (Choose one.)

- A. Only `HttpSessionListener`
- B. Only `HttpSessionBindingListener`
- C. Only `HttpSessionAttributeListener`
- D. `HttpSessionListener` and `HttpSessionBindingListener`
- E. `HttpSessionListener` and `HttpSessionAttributeListener`
- F. ` HttpSessionBindingLister`
- G. All three

10 Given that `req` is an `HttpServletRequest`, which snippets create a session if one doesn’t exist? (Choose all that apply.)

- A. `req.getSession();`
- B. `req.getSession(true);`
- C. `req.getSession(false);`
- D. `req.createSession();`
- E. `req.getNewSession();`
- F. `req.createSession(true);`
- G. `req.createSession(false);`
Given a session object `s` with two attributes named `myAttr1` and `myAttr2`, which will remove both attributes from this session? (Choose all that apply.)

- A. `s.removeAttributeValues();`
- B. `s.removeAttribute("myAttr1");`
- C. `s.removeAttribute("myAttr2");`
- D. `s.setAttribute("myAttr1", UNBIND);`
- E. `s.setAttribute("myAttr2", UNBIND);`

Which statements about `HttpSession` objects in distributed environments are true? (Choose all that apply.)

- A. When a session is moved from one JVM to another, any attributes stored in the session will be lost.
- B. When a session is moved from one JVM to another, appropriately registered `HttpSessionBindingListener` objects will be notified.
- C. When a session is moved from one JVM to another, appropriately registered `HttpSessionActivationListener` objects will be notified.
- D. When a session is moved from one JVM to another, attribute values that implement `java.io.Serializable` will be transferred to the new JVM.

Which statements about session timeouts are true? (Choose all that apply.)

- A. Session timeout declarations made in the DD can specify time in seconds.
- B. Session timeout declarations made in the DD can specify time in minutes.
- C. Session timeout declarations made programmatically can specify time only in seconds.
- D. Session timeout declarations made programmatically can specify time only in minutes.
- E. Session timeout declarations made programmatically can specify time in either minutes or seconds.
Choose the servlet code fragment that would retrieve from the request the value of a cookie named "ORA_UID".

A. String value = request.getCookie("ORA_UID");
B. String value = request.getHeader("ORA_UID");
C. `javax.servlet.http.Cookie[]` cookies = request.getCookies();
   String cName = null;
   String value = null;
   if (cookies != null){
      for (int i = 0; i < cookies.length; i++){
         cName = cookies[i].getName();
         if (cName != null & &
            cName.equalsIgnoreCase("ORA_UID")){
            value = cookies[i].getValue();
         }
      }
   }
D. `javax.servlet.http.Cookie[]` cookies = request.getCookies();
   if (cookies.length > 0){
      String value = cookies[0].getValue();
   }
How would you use the `HttpServletResponse` object in a servlet to add a cookie to the client?

- **A.** `<context-param>
  <param-name>myCookie</param-name>
  <param-value>cookieValue</param-value>
</context-param>`

- **B.** `response.addCookie("myCookie","cookieValue");`

- **C.**
  ```java
  javax.servlet.http.Cookie newCook =
  new javax.servlet.http.Cookie("myCookie","cookieValue");
  //...set other Cookie properties
  response.addCookie(newCook);
  ```

- **D.**
  ```java
  String cName = null;
  if (cookies != null) {
    for (int i = 0; i < cookies.length; i++) {
      cName = cookies[i].getName();
      if (cName != null &&
      cName.equalsIgnoreCase("myCookie")){
        out.println(cName + " : " + cookies[i].getValue());
      }
    }
  }
  ```
mock answers

Chapter 6. Conversational state

Given:

1. public class MyServlet extends HttpServlet {
2.   public void doGet(HttpServletRequest req,
3.                 HttpServletResponse res)
4.   throws IOException, ServletException {
5.     // request.getSession().setAttribute("key", "value");
6.     // request.getSession().setAttribute("key", "value");
7.     // ((HttpSession)request.getSession()).setAttribute("key", "value");
8.     } 
9. } 
10. 
11. Which line(s) could be uncommented without causing a compile or runtime error? (Choose all that apply.)
12. A. Line 15 only.
13. B. Line 14 only.
14. C. Line 15 only.
15. D. Line 16 only.
16. E. Line 13 or line 15. *Option E is correct because both lines 13 and 15 make the correct method call. The cast to HttpSession is NOT necessary, but it does reflect the correct type, so it is valid.*
17. F. Line 14 or line 16.

If a client will NOT accept a cookie, which session management mechanism could the web container employ? (Choose one.)

18. A. Cookies, but NOT URL rewriting.
19. B. URL rewriting, but NOT cookies. *Option B is correct because cookies CANNOT be used, but URL rewriting does NOT depend on cookies being enabled.*
20. C. Either cookies or URL rewriting can be used.
21. D. Neither cookies nor URL rewriting can be used.
22. E. Cookies and URL rewriting must be used together.
Which statements about HttpSession objects are true? (Choose all that apply.)

- A session whose timeout period has been set to -1 will never expire.
- A session will become invalid as soon as the user closes all browser windows.
- A session will become invalid after a timeout period defined by the servlet container.
- A session may be explicitly invalidated by calling HttpSession.invalidateSession().

Servlet v2.4 p. 59

Option B is incorrect because there is no explicit termination signal in the HTTP protocol.
Option D is incorrect because the method that should be used is called invalidate().

Which of the following are NOT listener event types in the J2EE 1.4 API? (Choose all that apply.)

- HttpSessionEvent
- ServletRequestEvent
- HttpSessionBindingEvent
- HttpSessionAttributeEvent
- ServletContextAttributeEvent

Servlet v2.4 p. 57

HttpSessionBindingEvents are used for both HttpSessionBindingListeners AND HttpSessionAttributeListeners.

Option C is incorrect because the specification dictates that the session tracking cookie must be JSESSIONID.
Option E is incorrect because there is no such class.

Which statements about session tracking are true? (Choose all that apply.)

- URL rewriting may be used by a server as the basis for session tracking.
- SSL has a built-in mechanism that a servlet container could use to obtain data used to define a session.
- When using cookies for session tracking, there is no restriction on the name of the session tracking cookie.
- When using cookies for session tracking, the name of the session tracking cookie must be JSESSIONID.
- If a user has cookies disabled in their browser, the container may choose to use a javax.servlet.http.CookielessHttpSession object to track the user's session.

Option C is incorrect because the specification dictates that the session tracking cookie must be JSESSIONID.
Option E is incorrect because there is no such class.
### mock answers

**6.**

Given:

```java
1. import javax.servlet.http.*;
2. public class MySessionListener
   implements HttpSessionListener {
3.     public void sessionCreated() {
4.         System.out.println("Session Created");
5.     }
6.     public void sessionDestroyed() {
7.         System.out.println("Session Destroyed");
8.     }
9. }
```

What is wrong with this class? (Choose all that apply.)

- A. The method signature on line 3 is NOT correct.
- B. The method signature on line 6 is NOT correct.
- C. The import statement will NOT import the `HttpSessionListener` interface.
- D. `sessionCreated` and `sessionDestroyed` are NOT the only methods defined by the `HttpSessionListener` interface.

---

**7.**

Which statements about session attributes are true? (Choose all that apply.)

- A. The return type of `HttpSession.getAttribute(String)` is `Object`.
- B. The return type of `HttpSession.getAttribute(String)` is `String`.
- C. Attributes bound into a session are available to any other servlet that belongs to the same `ServletContext`.
- D. Calling `setAttribute("keyA", "valueB")` on an `HttpSession` which already holds a value for the key `keyA` will cause an exception to be thrown.
- E. Calling `setAttribute("keyA", "valueB")` on an `HttpSession` which already holds a value for the key `keyA` will cause the previous value for this attribute to be replaced with the String `valueB`.

---

274 chapter 6
Which interfaces define a `getSession()` method? (Choose all that apply.)

- A. `ServletRequest`
- B. `ServletResponse`
- C. `HttpSessionRequest`
- D. `HttpSessionResponse`

Given a session object `s`, and the code:

`s.setAttribute("key", value);`

Which listeners could be notified? (Choose one.)

- A. Only ` HttpSessionListener`
- B. Only ` HttpSessionBindingListener`
- C. Only ` HttpSessionAttributeListener`
- D. ` HttpSessionListener` and ` HttpSessionBindingListener`
- E. ` HttpSessionListener` and ` HttpSessionAttributeListener`
- F. ` HttpSessionBindingListener` and ` HttpSessionAttributeListener`
- G. All three

Given that `req` is an `HttpServletRequest`, which snippets create a session if one doesn’t exist? (Choose all that apply.)

- A. `req.getSession();`
- B. `req.getSession(true);`  
  
  `--Options A and B will each create a new session if one doesn’t exist. `getSession(false)` returns a null if the session doesn’t exist.`
- C. `req.getSession(false);`
- D. `req.createSession();`
- E. `req.createSession();`
- F. `req.createSession(true);`
- G. `req.createSession(false);`
mock answers

11
Given a session object \( s \) with two attributes named \( \text{myAttr1} \) and \( \text{myAttr2} \), which will remove both attributes from this session? (Choose all that apply.)

- A. \( s \text{.removeAllValues}() \);
- B. \( s \text{.removeAttribute("myAttr1")};
   \( s \text{.removeAttribute("myAttr2")}; \)
- C. \( s \text{.removeAllAttributes}() \);
- D. \( s \text{.getAttribute("myAttr1", UNBIND)}; \)
  \( s \text{.getAttribute("myAttr2", UNBIND)}; \)
- E. \( s \text{.getAttributeNames}() \);

12
Which statements about \( \text{HttpSession} \) objects in distributed environments are true? (Choose all that apply.)

- A. When a session is moved from one JVM to another, any attributes stored in the session will be lost.
- B. When a session is moved from one JVM to another, appropriately registered \( \text{HttpSessionBindingListener} \) objects will be notified.
- C. When a session is moved from one JVM to another, appropriately registered \( \text{HttpSessionActivationListener} \) objects will be notified.
- D. When a session is moved from one JVM to another, attributes values that implement \text{java.io.Serializable} will be transferred to the new JVM.

13
Which statements about session timeouts are true? (Choose all that apply.)

- A. Session timeout declarations made in the DD can specify time in seconds.
- B. Session timeout declarations made in the DD can specify time in minutes.
- C. Session timeout declarations made programmatically can specify time only in seconds.
- D. Session timeout declarations made programmatically can specify time only in minutes.
- E. Session timeout declarations made programmatically can specify time in either minutes or seconds.

Chapter 6. Conversational state
Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: O'Reilly
Prepared for Stephen Goss, Safari ID: stephengoss@gmx.net
User number: 747221 Copyright 2007, Safari Books Online, LLC.
Choose the servlet code fragment that would retrieve from the request the value of a cookie named "ORA_UID"? (Choose all that apply.)

- Option A refers to a method that doesn't exist.

(A) API

- Option C gets a Cookie array using request.
- Option D only looks at the first Cookie in the array.

Option A refers to a method that doesn't exist.

Option C gets a Cookie array using request.getCookie("ORA_UID").

Option D only looks at the first Cookie in the array.
mock answers

How would you use the HttpServletRequest object in a servlet to add a cookie to the client?

A. `<context-param>`
   `<param-name>myCookie</param-name>`
   `<param-value>cookieValue</param-value>`
   `</context-param>`

B. `response.addCookie("myCookie","cookieValue");`

C. `java.servlet.http.Cookie newCook =
   new java.servlet.http.Cookie("myCookie","cookieValue");`
   `//...set other Cookie properties`
   `response.addCookie(newCook);`

D. `java.servlet.http.Cookie[] cookies = request getCookies();`
   `String cName = null;`
   `if (cookies != null){`
     for (int i = 0; i < cookies.length; i++){
       `cName = cookies[i].getName();`
       `if (cName != null &&`
       `cName.equalsIgnoreCase("myCookie")){`
         `out.println("cName + " + cookies[i].getValue();`
       }`
     }`
   }`

---

- Option B is not correct because the addCookie method takes a Cookie object, not Strings.
- Option D is not correct because it shows servlet code retrieving, not creating, a cookie.
7 using JSP

Being a JSP

A JSP becomes a servlet. A servlet that you don’t create. The container looks at your JSP, translates it into Java source code, and compiles it into a full-fledged Java servlet class. But you’ve got to know what happens when the code you write in the JSP is turned into Java code. You can write Java code in your JSP, but should you? And if you don’t write Java code, then what do you write? How does it translate into Java code? In this chapter, we’ll look at six different kinds of JSP elements—each with its own purpose and, yes, unique syntax. You’ll learn how, why, and what to write in your JSP. Perhaps more importantly, you’ll learn what not to write in your JSP.
official Sun exam objectives

**OBJECTIVES**

The JSP Technology Model

6.1 Identify, describe, or write JSP code for the following elements: (a) template text, (b) scripting elements (comments, directives, declarations, scriptlets, and expressions), (c) standard and custom actions, and (d) expression language elements.

6.2 Write JSP code that uses the directives: (a) page (with attributes import, session, contentType, and isEL:Ignored), (b) include, and (c) taglib.

6.3 Write a JSP Document (XML-based document) that uses the correct syntax.

6.4 Describe the purpose and event sequence of the JSP page lifecycle: (1) JSP page translation, (2) JSP page compilation, (3) load class, (4) create instance, (5) call the jspInit method, (6) call the _jspService method, and (7) call the _jspDestroy method.

6.5 Given a design goal, write JSP code using the appropriate implicit objects: (a) request, (b) response, (c) out, (d) session, (e) config, (f) application, (g) page, (h) pageContext, and (i) exception.

6.6 Configure the deployment descriptor to declare one or more tag libraries, deactivate the evaluation language, and deactivate the scripting language.

6.7 Given a specific design goal for including a JSP segment in another page, write the JSP code that uses the most appropriate inclusion mechanism (the include directive or the jsp:include standard action).

Coverage Notes:

Most is covered in this chapter, but the details behind (c) standard and custom actions, and (d) expression language elements are covered in later chapters.

The page directive is covered in this chapter, but include and taglib are covered in later chapters.

Not covered here; refer to the chapter on Deployment.

All covered in this chapter. (Hint: these will be some of the most no-brainer questions on the real exam, once you’ve learned the fundamentals in this chapter.)

All covered in this chapter, although you’re expected to already know what most of them mean based on the previous two chapters.

We cover everything here except declaring tag libraries. That’s covered in the chapter on Using JSTL.

Not covered here; refer to the next chapter (Scriptless JSPs).

280 chapter 7
In the end, a JSP is just a servlet

Your JSP eventually becomes a full-fledged servlet running in your web app. It’s a lot like any other servlet, except that the servlet class is written for you—by the Container.

The Container takes what you’ve written in your JSP, translates it into a servlet class source (.java) file, then compiles that into a Java servlet class. After that, it’s just servlets all the way down, and the servlet runs in exactly the same way it would if you’d written and compiled the code yourself. In other words, the Container loads the servlet class, instantiates and initializes it, makes a separate thread for each request, and calls the servlet’s service() method.

Some of the questions we’ll answer in this chapter include:

- Where does each part of your JSP file end up in the servlet source code?
- Do you have access to the “servletness” of your JSP page? For example, does a JSP have a concept of a ServletConfig or ServletContext?
- What are the types of elements you can put in a JSP?
- What’s the syntax for the different elements in a JSP?
- What’s the lifecycle of a JSP, and can you step into the middle of it?
- How do the different elements in a JSP interact in the final servlet?
Making a JSP that displays how many times it’s been accessed

Pauline wants to use JSPs in her web apps—she’s really sick of writing HTML into a servlet’s PrintWriter println(). She decides to learn JSPs by making a simple dynamic page that prints the number of times the page has been requested. She understands that you can put regular old Java code in a JSP using a scriptlet—which just means Java code within a <% ... %> tag.

I know I can put Java code in the JSP, so I’ll make a static method in a Counter class to hold the access count static variable, and then I’ll call that method from the JSP.

```
BasicCounter.jsp
<html>
<body>
The page count is:
<% out.println(Counter.getCount()); %>
</body>
</html>
```

```
Counter.java
package foo;

public class Counter {
    private static int count;
    public static synchronized int getCount() {
        count++;
        return count;
    }
}
```

Plain old Java helper class.
She deploys and tests it

It’s trivial to deploy and test. The only tricky part is making sure that the Counter class is available to the JSP, and that’s easy—just be sure the Counter class is in the WEB-INF/classes directory of the web app. She accesses the JSP directly in the browser at:

http://localhost:8080/testJSP1/BasicCounter.jsp

What she expected:

The page count is: 1

What she got:

HTTP Status 500

The server encountered an internal error () that prevented it from fulfilling this request.

An error occurred at line: 1 in the jsp file: /BasicCounter.jsp

Generated servlet error:

java: Compiling 1 source file

/Users/Kathy/Applications/jakarta-tomcat-5.0.19/work/Catalina/localhost/testJSP1/org/apache/jsp/BasicCounter.jsp java:45: cannot resolve symbol

symbol : variable Counter

location: class org.apache.jsp.basicCounter.jsp

cout();

Can you figure out what’s wrong?

1 error

org.apache.jasper.compiler.DefaultErrorHandler.java55
org.apache.jasper.compiler.Compiler.getEnclosingClass(Compiler.java:415)
org.apache.jasper.compiler.Compiler.makeClass(Compiler.java:458)
org.apache.jasper.servlet.JspServletWrapper.service(JspServletWrapper.java:291)
org.apache.jasper.servlet.JspServlet.service(JspServlet.java:291)
org.apache.jasper.servlet.JspServlet.service(JspServlet.java:249)
javax.servlet.http.HttpServlet.service(HttpServlet.java:856)
The JSP doesn’t recognize the Counter class

The Counter class is in the foo package, but there’s nothing in the JSP to acknowledge that. It’s the same thing that happens to you with any other Java code, and you know the rule: import the package or use the fully-qualified class name in your code.

I guess you have to use the fully-qualified class name inside JSPs. That makes sense, since all JSPs are turned into plain old Java servlet code by the Container. But I sure wish you could put imports into your JSP code...

```
Counter.java

package foo;

public class Counter {
  private static int count;
  public static int getCount() {
    count++;
    return count;
  }
}
```

JSP code was:
```
<% out.println(Counter.getCount()); %>
```

JSP code should be:
```
<% out.println(foo.Counter.getCount()); %>
```

Now it’ll work.
Use the page directive to import packages

A *directiv* is a way for you to give special instructions to the Container at page translation time. Directives come in three flavors: *page, include,* and *taglib.* We’ll look at the include and taglib directives in later chapters, but for now all we care about is the *page* directive, because it’s the one that lets you *import.*

To import a single package:

```jsp
<%@ page import="foo.*" %>
<html>
<body>
The page count is:
<% out.println(Counter.getCount()); %>
</body>
</html>
```

Notice what’s different between the Java code that prints the counter and the page directive?

The Java code is between angle brackets with percent signs: `<%` and `%>`. But the directive adds an additional character to the start of the element—the `@` sign!

*If you see JSP code that starts with `<%@`, you know it’s a directive. (We’ll get into more details about the page directive later in the book.)*

To import multiple packages:

```jsp
<%@ page import="foo.*,java.util.*" %>
```

*Use a comma to separate the packages. The quotes go around the entire list of packages!*

But you CAN put import statements in a JSP... you just need a directive.
But then Kim mentions “expressions”

Just when you thought it was safe, Kim notices the scriptlet with an out.println() statement. This is JSP, folks. Part of the whole point of JSP is to avoid println()! That’s why there’s a JSP expression element—it automatically prints out whatever you put between the tags.

You don’t need to say out.println() in a JSP! Just use an expression...

Scriptlet code:

```jsp
<%@ page import="foo.*" %>
<html>
<body>
The page count is:
<% out.println(Counter.getCount()); %>
</body>
</html>
```

Expression code:

```jsp
<%@ page import="foo.*" %>
<html>
<body>
The page count is now:
<%= Counter.getCount() %>
</body>
</html>
```

Notice what’s different between the tag for the scriptlet code and the tag for the expression? The scriptlet code is between angle brackets with percent signs: <% and %>. But the expression adds an additional character to the start of the element—an equals sign (=).

So far we’ve seen three different JSP element types:

- Scriptlet: `<%@ %>`
- Directive: `<%@ %>`
- Expression: `<%= %>`
where's the semicolon?

Expressions become the argument to an out.print()

In other words, the Container takes everything you type between the <%% and %> and puts it in as the argument to a statement that prints to the implicit response PrintWriter out.

When the Container sees this:

```<%= Counter.getCount() %>`

It turns it into this:

```out.print(Counter.getCount());```  

If you did put a semicolon in your expression:

```<%= Counter.getCount(); %>```  

That would be bad. It would mean this:

```out.print(Counter.getCount());```  

Yikes!! This will never compile.

NEVER end an expression with a semicolon!

```<%= neverPutASemicolonInHere %>```  
```<%= becauseThisIsAnArgumentToWrite %>```

you are here → 287
expressions and page directive

therefore go Durnt Questions

Q: Well, if you’re supposed to use expressions INSTEAD of putting out.println() into a scriptlet, then why is the implicit “out” there?

A: You probably won’t use the implicit out variable from within your JSP page, but you might pass it to something else... some other object that’s part of your app that does not have direct access to the output stream for the response.

Q: In an expression, what happens if the method doesn’t return anything?

A: You’ll get an error! You cannot, MUST NOT use a method with a void return type as an expression. The Container is smart enough to figure out that there won’t be anything to print if the method has a void return type!

Q: Why does the import directive start with the word “page”? Why is it <%@ page import=”%> instead of just <%@ import=”%>.

A: Good question! Rather than having a whole big pile of different directives, the JSP spec has just three JSP directives, but the directives can have attributes. What you called “the import directive” is actually “the import attribute of the page directive”.

Q: What are the other attributes for the page directive?

A: Remember, the page directive is about giving the Container information it needs when translating your JSP into a servlet. The attributes we care about (besides import) are session, content-Type, and isElIgnored (we’ll come back to these later in the chapter).
Kim drops the final bombshell...

You don't even NEED the Counter class... you can do the whole thing in the JSP.

Hmmm... I know the JSP turns into a servlet, so maybe I could declare a count variable in a scriptlet and that would turn into a variable in the servlet. Would that work?

What she tried:

```html
<html>
<body>
<% int count=0; %>
The page count is now:
<%= ++count %>
</body>
</html>
```

Will it compile?
Will it work?

**Declaring a variable in a scriptlet**

The variable declaration is legal, but it didn’t quite work the way Pauline hoped.

**What she tried:**

```
<html>
<body>
<scriptlet>
  int count = 0;
  declare the count variable
</scriptlet>
<body>
</html>
```

```
<%= ++count %>
increment the count variable and print the value.
```

**What she got the first time she hit the page:**

```
The page count is: 1
Looks good!
```

**What she got the second, third, and every other time she hit the page:**

```
The page count is: 1
Uh-oh... it's still showing '1'
It keeps resetting the variable.
```
What REALLY happens to your JSP code?

You write a JSP, but it becomes a servlet. The only way to really tell what's happening is to look at what the Container does to your JSP code. In other words, how does the Container translate your JSP into a servlet?

Once you know where different JSP elements land in the servlet's class file, you'll find it much easier to know how to structure your JSP. The servlet code on this page is not the real code generated by the Container—we simplified it down to the essential parts. The Container-generated servlet file is, well, aglor. The real generated servlet source code is slightly harder to read, but we will look at the real thing in a few pages. For now, though, all we care about is where in the servlet class our JSP code actually ends up.

This JSP:

```
<% int count=0 %>  
The page count is now: 1; 
<%= ++count %>  
</body></html>
```

Becomes this servlet:

```
public class basicCounter_jsp extends SomeSpecialHttpServletRequest {

    public void _jspService(HttpServletRequest request, 
        HttpServletResponse response) throws ServletException, 
            IOException {

        PrintWriter out = response.getWriter();
        response.setContentType("text/html");

        out.println("<html><body>");
        int count = 0;
        out.println("The page count is now: ");
        out.println(++count);
        out.println("</body></html>" );
    }
}
```

The Container puts all the code into a generic service method. Think of it as a catch-all combo `doGet/doPost`.

```
ALL scriptlet and expression code  
lands in a service method.  
That means variables declared in a scriptlet are always LOCAL variables!
```

Note: if you want to see the generated servlet code from Tomcat, look in:
```
yourTomcatHomeDir/work/Catalina/yourServerName/yourWebAppName/org/apache/jsp.
```
(The underlined names will change depending on your system and your web app.)

Chapter 7. Being a JSP

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher:Prepared for Augusto Jaramillo Forcada, Safari ID: augustojf.cv@gmail.com

Print Publication Date: 8/1/2004

This PDF is exclusively for your use in accordance with the Safari Terms of Service. No part of it may be reproduced or transmitted in any form by any means without the prior written permission for reprints and excerpts from the publisher. Redistribution or other use that violates the fair use privilege under U.S. copyright laws (see 17 USC107) or that otherwise violates the Safari Terms of Service is strictly prohibited.
Don’t tell me—there must be another kind of JSP element for declaring instance variables instead of local variables...

We need another JSP element...

Declaring the count variable in a scriptlet meant that the variable was reinitialized each time the service method ran. Which means it was reset to 0 with each request. We need to somehow make count an instance variable.

So far we’ve looked at directives, scriptlets, and expressions. **Directives** are for special instructions to the Container, **scriptlets** are just plain old Java that lands as-is within the generated servlet’s service method, and the result of an **expression** always becomes the argument to a print() method.

But there’s another JSP element called a **declaration**.

```jsp
<jsp: declaration>
  <%! int count = 0; %>
</jsp: declaration>
```

**JSP declarations** are for declaring members of the generated servlet class. That means both variables and methods! In other words, anything between the `<%!` and `%>` tag is added to the class **outside** the service method.

That means you can declare both static and instance variables and methods.
**JSP Declarations**

A JSP declaration is always defined *inside* the class but *outside* the service (or any other) method. It’s that simple—declarations are for static and instance variables and methods. (In theory, yes, you could define other members including inner classes, but 99.9999% of the time you’ll use declarations for methods and variables.) The code below solves Pauline’s problem; now the counter keeps incrementing each time a client requests the page.

**Variable Declaration**

This JSP:

```java
public class basicCounter_jsp extends HttpServlet {

    int count=0;

    public void _jspService(HttpServletRequest request, HttpServletResponse response)
        throws java.io.IOException {
        PrintWriter out = response.getWriter();
        out.setContentType("text/html");
        out.println("<html><body>");
        out.println("Two int count=0;
        The page count is now: "+(count);
        out.println("</body></html>");
    }
}
```

**Method Declaration**

This JSP:

```java
public class basicCounter_jsp extends HttpServlet {

    int count=0;
    int doubleCount() {
        count = count*2;
        return count;
    }

    public void _jspService(HttpServletRequest request, HttpServletResponse response)
        throws java.io.IOException {
        PrintWriter out = response.getWriter();
        response.setContentType("text/html");
        out.println("<html><body>");
        out.println("The page count is now: "+(count);
        out.println("</body></html>");
    }
}
```
the generated servlet

Time to see the REAL generated servlet

We’ve been looking at a supersimplified version of the servlet the Container actually creates from your JSP. There’s no need to look at the Container-generated code during development, but you can use it to help learn. Once you’ve seen what the Container does with the different elements of a JSP, you shouldn’t need to ever look at the Container-generated .java source files. Some vendors won’t let you see the generated Java source, and keep only the compiled .class files.

Don’t be intimidated when you see parts of the API that you don’t recognize. Most of the class and interface types are vendor-specific implementations you shouldn’t care about.

What the Container does with your JSP

- Looks at the directives, for information it might need during translation.
- Creates an HttpServlet subclass.
  For Tomcat 5, the generated servlet extends:
  `org.apache.jasper.runtime.HttpJspBase`
- If there’s a page directive with an import attribute, it writes the import statements at the top of the class file, just below the package statement.
  For Tomcat 5, the package statement (which you don’t care about) is:
  `package org.apache.jsp;`
- If there are declarations, it writes them into the class file, usually just below the class declaration and before the service method. Tomcat 5 declares one static variable and one instance method of its own.
- Builds the service method. The service method’s actual name is `_jspService()`. It’s called by the servlet superclass’ overridden service() method, and receives the HttpServletRequest and HttpServletResponse. As part of building this method, the Container declares and initializes all the implicit objects. (You’ll see more implicit objects when you turn the page.)
  - Combines the plain old HTML (called template text), scriptlets, and expressions into the service method, formatting everything and writing it to the PrintWriter response output.
The Container puts YOUR declarations (things inside `<%! %> tags) and any of its own below the class declaration.

The Container declares a bunch of its own local variables, including those that represent the "implicit objects" your code might need, like "out" and "request." Now it tries to initialize the implicit objects. And it tries to run and output your JSP HTML, scriptlet, and expression code.

Of course things might go wrong...

The Container puts YOUR code to work and outputs the HTML page to the user.
The out variable isn't the only implicit object...

When a Container translates the JSP into a servlet, the beginning of the service method is a pile of implicit object declarations and assignments.

With implicit objects, you can write a JSP knowing that your code is going to be part of a servlet. In other words, you can take advantage of your servletness, even though you're not directly writing a servlet class yourself.

Think back to chapters 4, 5, and 6. What were some of the important objects you used? How did your servlet get servlet init parameters? How did your servlet get context init parameters? How did your servlet get a session? How did your servlet get the parameters submitted by the client in a form?

These are just a few of the reasons your JSP might need to use some of what's available to a servlet. All of the implicit objects map to something from the Servlet/JSP API. The request implicit object, for example, is a reference to the HttpServletRequest object passed to the service method by the Container.

### API vs. Implicit Object

<table>
<thead>
<tr>
<th>Implicit Object</th>
<th>API</th>
</tr>
</thead>
<tbody>
<tr>
<td>out</td>
<td>JspWriter</td>
</tr>
<tr>
<td>request</td>
<td>HttpServletRequest</td>
</tr>
<tr>
<td>response</td>
<td>HttpSession</td>
</tr>
<tr>
<td>session</td>
<td>ServletContext</td>
</tr>
<tr>
<td>application</td>
<td>ServletConfig</td>
</tr>
<tr>
<td>config</td>
<td>JspException</td>
</tr>
<tr>
<td>exception</td>
<td>PageContext</td>
</tr>
<tr>
<td>pageContext</td>
<td>Object</td>
</tr>
</tbody>
</table>

Q: What's the difference between a JspWriter and a PrintWriter I get from an HttpServletResponse?

A: Not much. The JspWriter IS A PrintWriter, but it adds some buffering capabilities. The only time you really care about that is when you're building custom tags, so we'll talk a little about JspWriter's special capabilities in the chapter on developing custom tags.
Exercise

Each of the listings is from a JSP. Your job is to figure out what will happen when the container tries to turn the JSP into a servlet. Will the container be able to translate your JSP into legal, compilable servlet code? If not, why not? If so, what happens when a client accesses the JSP?

```html
<html><body>
Test scriptlets...
<% int y=3*x; %>
<% int x=2; %>
</body></html>
```

```html
<%@ page import="java.util.*" %>
<html><body>
Test scriptlets...
<% ArrayList list = new ArrayList();
    list.add(new String("foo"));
%>
<% list.get(0) %>
</body></html>
```

```html
<html><body>
Test scriptlets...
<! int x = 42; %>
<! int x = 22; %>
<! x %>
</body></html>
```

you are here 297
**JSP exercise**

**Mock Exam Magnets**

Study the scenario (and everything else on this page), then place the magnets on the JSP to make a legal file that would produce the correct result. You don’t have to use any magnet more than once, and you won't use all of the magnets. This exercise assumes there’s a servlet (which you don’t need to see) that takes the initial request, binds an attribute into the request scope, and forwards to the JSP you’re creating.

(Note: we called this ‘Mock Exam Magnets’ instead of ‘Code Magnets’ because the exam is FULL of Drag and Drop questions like this one.)

**Design Goal**

Create a JSP that will produce this:

```
The friends who share your hobby of extreme knitting are:
Fred
Pradeep
Philippe
```

The three names come from an ArrayList request attribute called 'names'. You’ll need to get the attribute from the request object. Assume a servlet got this request and set an attribute in request scope.

**The HTML form**

```html
<html>
<body>
<form method="POST">
    action="#HobbyPage/do">
    Choose a hobby:<p>
    <select name="hobby" size="1">
    <option>horse skiing</option>
    <option>extreme knitting</option>
    <option>alert scuba</option>
    <option>speed dating</option>
</select>
<br />
<center>
    <input type="SUBMIT">
</center>
</form>
</body>
</html>
```

- The request attribute is of type java.util.ArrayList.
- The implicit variable for the HttpServletRequest object is named request, and you can use it within scriptlets or expressions, but not within directives or declarations. Whatever you can do with a request object in a servlet, you do inside your JSP.
- A JSP's servlet method can process request parameters, because remember, your code is going to be inside a servlet's service method. You don’t have to worry about which of the HTTP methods (GET or POST) was used in the request.

---

Chapter 7. Being a JSP

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher:Prepared for Augusto Jaramillo Forcada, Safari ID: augustojf.cv@gmail.com

Print Publication Date: 8/1/2004

We've put a few lines in for you. The code you put in this JSP MUST work with the code that's already here. When you're done, it should be compilable and produce the result on the opposite page (you must ASSUME that there's already a working servlet that first gets the request, sets the request attribute "names", and forwards the request to this JSP).

The friends who share your hobby of

are: <br>

<% Iterator it = al.iterator();
<br>
<% } %>

You won't use all of these!
Chapter 7. Being a JSP

exercise answers

BE the Container

Answers

#2 is straightforward and works. #1 is a fundamental Java language issue (using a local variable before it's declared), and #3 also demonstrates a fundamental Java language issue—what happens when you have an instance and local variable with the same name. So you see... if you translate the JSP code into servlet Java code, you'll have no trouble figuring out the result. Once your JSP stuff is inside a servlet, it's just Java.

```java
<body>
    Test scriptlets...
    <% int y = 5 + x; %>
    <% int x = 2; %>
</body>
</html>

void foo() {
    int y = 5 + x;
    int x = 2;
}
```

You're trying to use variable 'x' BEFORE it's defined. The Java language doesn't allow that, and the Container won't bother to rearrange the order of your scriptlet code.

```java
<html><body>
    Test scriptlets...
    <%= this.x %>
</body></html>
```

No problems; prints the first (and only) object in the ArrayList.

```java
<html><body>
    Test scriptlets...
    <script>
        var list = new ArrayList();
        list.add('foo');
        var x = list.get(0);
    </script>
</body></html>
```
If your answer looks a little different, but you still think it should work—try it! You’ll have to make the servlet that takes the form request, sets an attribute, and forwards (dispatches) the request to the JSP.

```html
<%@ page import="java.util.*" %>

<html>
<body>

The friends who share your hobby of

```java
request.getParameter("hobby")
```

are: <br>

```java
ArrayList al = (ArrayList) request.getAttribute("names");

Iterator it = al.iterator();

while (it.hasNext()) {

    System.out.println(it.next());

}<br>

</body>
</html>
```

We need the import page directive because of ArrayList and Iterator.

Start a scriptlet up here...

and end it here.

Use an expression.

Finish the while loop block! (If you forget this, it won’t compile).
valid and invalid expressions

A comment...

Yes, you can put comments in your JSP. If you’re a Java programmer with very little HTML experience, you might find yourself typing:

```java
// this is a comment
```

without thinking twice. But if you do, then unless it’s within a scriptlet or declaration tag, you’ll end up DISPLAYING that to the client as part of the response. In other words, to the Container, those two slashes are just more template text, like “Hello” or “Email us.”

You can put two different types of comments in a JSP:

- `<-- HTML comment -->`

  The Container just passes this straight on to the client, where the browser interprets it as a comment.

- `<%= JSP comment -->%>
  These are for the page developers, and just like Java comments in a Java source file, they’re stripped out of the translated page. If you’re typing a JSP and want to put in comments about what you’re doing, the way you’d use comments in a Java source file, use a JSP comment.

If you want comments to stay as part of the HTML response to the client (although the browser will hide them from the client’s view), use an HTML comment.

Valid and Invalid Expressions

<table>
<thead>
<tr>
<th>Valid?</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;%= 27 %&gt;</code></td>
</tr>
<tr>
<td>All primitive literals are fine.</td>
</tr>
<tr>
<td><code>&lt;%= (Math.random() + 5)*2 }; %&gt;</code></td>
</tr>
<tr>
<td>NO! The semicolon can’t be here.</td>
</tr>
<tr>
<td><code>&lt;%= “27” %&gt;</code></td>
</tr>
<tr>
<td>String literal is fine.</td>
</tr>
<tr>
<td><code>&lt;%= Math.random () %&gt;</code></td>
</tr>
<tr>
<td>Yes, the method returns a double.</td>
</tr>
<tr>
<td><code>&lt;%= String s = “foo” %&gt;</code></td>
</tr>
<tr>
<td>NO! You can’t have a variable declaration here.</td>
</tr>
<tr>
<td><code>&lt;%= new String(&quot;3&quot;) %&gt;</code></td>
</tr>
<tr>
<td>Yes, because the new String array is an object, and ANY object can be sent to a println() statement.</td>
</tr>
<tr>
<td><code>&lt;%= 42*20 %&gt;</code></td>
</tr>
<tr>
<td>NO! The arithmetic is fine, but there’s a space between the % and the =. It can’t be <code>&lt;% =</code>, it must be <code>&lt;%= </code>.</td>
</tr>
<tr>
<td><code>&lt;%= 5 &gt; 3 %&gt;</code></td>
</tr>
<tr>
<td>Sure, this resolves to a boolean, so it prints ‘true’.</td>
</tr>
<tr>
<td><code>&lt;%= false %&gt;</code></td>
</tr>
<tr>
<td>We already said primitive literals are fine.</td>
</tr>
<tr>
<td><code>&lt;%= new Counter() %&gt;</code></td>
</tr>
<tr>
<td>No problem. This is just like the String[J, it prints the result of the object’s toString() method.</td>
</tr>
</tbody>
</table>
API for the generated servlet

The Container generates a class from your JSP that implements the JspPage interface. This is the only part of the generated servlet's API that you need to know. You don’t care that in Tomcat, for example, your generated servlet extends:

org.apache.jasper.runtime.HttpJspBase

All you need to know about are the three key methods:

- **jspInit()**
  - This method is called from the init() method.
  - You can override this method. (Can you figure out how?)

- **jspDestroy()**
  - This method is called from the servlet's destroy() method.
  - You can override this method as well.

- **_jspService()**
  - This method is called from the servlet's service() method, which means it runs in a separate thread for each request.
  - The Container passes the Request and Response objects to this method.
  - You can't override this method! You can’t do ANYTHING with this method yourself (except write code that goes inside it), and it's up to the Container vendor to take your JSP code and fashion the _jspService() method that uses it.

You can override these.

You **CANNOT** override this!

---

**Note the underscore at the front of the _jspService() method**

It’s NOT in front of the other two methods, jspInit() and jspDestroy(). Think of it this way: the underscore in front of the method name means “don’t touch!”

So, no underscore in front of the method name means you can override. But if there is an underscore in front of the method name, you must **NOT** try to override it!
**JSP lifecycle**

**Lifecycle of a JSP**

You write the `.jsp` file. The Container writes the `.java` file for the servlet your JSP becomes.

1. Kim writes a `.jsp` file, and deploys it as part of a web app.
2. The client hits a link that asks for the `.jsp`.
3. The Container tries to COMPILE the servlet `.java` source into a class file.

The Container "reads" the `web.xml` (DD) for this app, but doesn't do anything else with the `.jsp` file (until the first time it's requested).

"It's just sitting here on the server...waiting for a client to request it."

"JSP syntax errors are caught in this phase."

"Java language/syntax errors are caught here."

304 chapter 7
JSP lifecycle continued...

1. The Container LOADs the newly-generated servlet class.

2. The Container instantiates the servlet and causes the servlet's jspInit() method to run.

3. The Container creates a new thread to handle this client's request, and the servlet's _jspService() method runs.

Everything that happens after this is just plain old servlet request-handling.

Eventually the servlet sends a response back to the client (or forwards the request to another web app component).
Wow, I am truly impressed. I would never have guessed that they could make requesting a JSP take just as much overhead as calling a method on an EJB. I'm thinking the client has to wait, what, five minutes for all that translating, compiling, and initializing?

### Translation and compilation happens only ONCE

When you deploy a web app with a JSP, the whole translation and compilation step happens only once in the JSP's life. Once it's been translated and compiled, it's just like any other servlet. And just like any other servlet, once that servlet has been loaded and initialized, the only thing that happens at request time is creation or allocation of a thread for the service method. So the picture on the previous two pages is for only the first request.

**Q:** OK, so that means only the first client to ask for the JSP takes the big hit. But there MUST be a way to configure the server to pre-translate and compile...right?

**A:** Although it's only the first client that has to wait, most Container vendors DO give you a way to ask for the whole translation/compilation thing to happen in advance, so that even the first request happens like any other servlet request.

But watch out—it's vendor-dependent and not guaranteed. There is a mention in the JSP spec (JSP 1.1.4.2) of a suggested protocol for JSP precompilation. You make a request for the JSP appending a query string "/jsp_precompile" and the Container might (if it chooses) do the translation/compilation right then instead of waiting for the first real request.
If the JSP turns into a servlet, I wonder if I can configure servlet init parameters... and while I'm at it, I wonder if I can override the servlet's init() method.

Sharpen your pencil

Think about these questions. Flip back through earlier pages (and chapters) if you need to, but don't turn the page until you've done this.

Yes, you CAN get servlet init parameters from a servlet, the questions are:

1) How would you retrieve them in your code? (Big, huge, gravel-hauling hint: pretty close to the same way you retrieve them in a "normal" servlet. From which object do you normally get servlet init parameters? Is that object available to your JSP code?)

2) How/where would you configure the servlet init parameters?

3) Suppose you do want to override the init() method... how would you do it? Is there something else you can do that'll give you the same result?
overriding \texttt{jspInit()}

\section*{Initializing your JSP}

You can do servlet initialization stuff in your JSP, but it’s \textit{slightly} different from what you do in a regular servlet.

\section*{Configuring servlet init parameters}

You configure servlet init params for your JSP virtually the same way you configure them for a normal servlet. The only difference is that you have to add a \texttt{<jsp-file>} element within the \texttt{<servlet>} tag.

\begin{verbatim}
<web-app ...>
  ...
  <servlet>
    <servlet-name>MyTestInit</servlet-name>
    \texttt{<jsp-file>/TestInit.jsp</jsp-file>}
    <init-param>
      \texttt{<param-name>email</param-name>}
      \texttt{<param-value>kickedbutt@wickedlysmart.com</param-value>}
    </init-param>
  </servlet>
  ...
</web-app>
\end{verbatim}

\subsection*{Overriding \texttt{jspInit()}}

Yes, it’s that simple. If you implement a \texttt{jspInit()} method, the Container calls this method at the beginning of this page’s life as a servlet. It’s called from the servlet’s \texttt{init()} method, so by the time this method runs there is a ServletConfig and ServletContext available to the servlet. That means you can call \texttt{getServletConfig()} and \texttt{getServletContext()} from within the \texttt{jspInit()} method.

This example uses the \texttt{jspInit()} method to retrieve a servlet init parameter (configured in the DD), and uses the value to set an application-scoped attribute.

\begin{verbatim}
public void jspInit()
{
    ServletConfig sConf = getServletConfig();
    String emailAddr = sConf.getInitParameter("email");
    ServletContext ctx = getServletContext();
    ctx.setAttribute("mail", emailAddr);
}
\end{verbatim}
Attributes in a JSP

The example on the opposite page shows the JSP setting an application-scoped attribute using a method declaration that overrides `setAttribute()`. But most of the time you’ll be using one of the four implicit objects to get and set attributes corresponding to the four attribute scopes available in a JSP.

Yes, four. Remember, in addition to the standard servlet request, session, and application (context) scopes, a JSP adds a fourth scope—page scope—that you get from a `pageContext` object.

You usually won’t need (or care about) page scope unless you’re developing custom tags, so we won’t say any more about it until the custom tags chapter.

<table>
<thead>
<tr>
<th>In a servlet</th>
<th>In a JSP (using implicit objects)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Application</strong></td>
<td><code>getServletContext().setAttribute(&quot;foo&quot;, barObj);</code></td>
</tr>
<tr>
<td><strong>Request</strong></td>
<td><code>request.setAttribute(&quot;foo&quot;, barObj);</code></td>
</tr>
<tr>
<td><strong>Session</strong></td>
<td><code>request.getSession().setAttribute(&quot;foo&quot;, barObj);</code></td>
</tr>
<tr>
<td><strong>Page</strong></td>
<td>Does not apply!</td>
</tr>
</tbody>
</table>

But this isn’t the whole story! In a JSP, there’s another way to get and set attributes at any scope, using only the `pageContext` implicit object. Turn the page and find out how...
**Using PageContext for attributes**

You can use a PageContext reference to get attributes from any scope, including the page scope for attributes bound to the PageContext.

The methods that work with other scopes take an int argument to indicate the scope. Although the attribute access methods come from JspContext, you’ll find the constants for the scopes inside the PageContext class.
Examples using pageContext to get and set attributes

Setting a page-scoped attribute

```jsp
<% Float one = new Float(42.5); %>
<% pageContext.setAttribute("foo", one); %>  
```

Getting a page-scoped attribute

```jsp
<%= pageContext.getAttribute("foo") %>
```

Using the pageContext to set a session-scoped attribute

```jsp
<% Float two = new Float(22.4); %>
<% pageContext.setAttribute("foo", two, PageContext.SESSION_SCOPE); %>  
```

Using the pageContext to get a session-scoped attribute

```jsp
<%= pageContext.getAttribute("foo", PageContext.SESSION_SCOPE) %>
(Which is identical to: <%= session.getAttribute("foo") %>)
```

Using the pageContext to get an application-scoped attribute

```jsp
Email is:
<%= pageContext.getAttribute("mail", PageContext.APPLICATION_SCOPE) %>
```

Within a JSP, the code above is identical to:

```jsp
Email is:
<%= application.getAttribute("mail") %>
```

Using the pageContext to find an attribute when you don’t know the scope

```jsp
<%= pageContext.findAttribute("foo") %>
```

Finding it where?

Where does the findAttribute() method look? It looks first in the page context, so if there’s a “foo” attribute with page context scope, then calling findAttribute(String name) on a PageContext works just like calling getattr(String name) on a PageContext. But if there’s no “foo” attribute, the method starts looking in other scopes, from most restricted to least restricted scope—in other words, first request scope, then session, then finally application scope. The first one it finds with that name wins.
three directives

While we’re on the subject... let’s talk more about the three directives

We already looked at the directive used for getting import statements into the generated servlet class made from your JSP. That was a page directive (one of the three directive types) with an import attribute (one of 13 attributes of the page directive). We’ll take a quick look now at the others, although some won’t be covered in detail until later chapters, and some won’t be covered in detail at all in this book, because they’re rarely used.

1. **The page directive**

   ```xml
   <%@ page import="foo," session="false" %>
   ```

   Defines page-specific properties such as character encoding, the content type for this page’s response, and whether this page should have the implicit session object. A page directive can use up to thirteen different attributes (like the import attribute), although only four attributes are covered on the exam.

2. **The taglib directive**

   ```xml
   <%@ taglib uri="/WEB-INF/tags/cool" prefix="cool" %>
   ```

   Defines tag libraries available to the JSP. We haven’t talked about using custom tags and standard actions yet, so this might not make any sense at this point. Just go with it for now... we have two whole chapters on tag libraries coming up soon.

3. **The include directive**

   ```xml
   <%@ include file="wickedHeader.html" %>
   ```

   Defines text and code that gets added into the current page at translation time. This lets you build reusable chunks (like a standard page heading or navigation bar) that can be added to each page without having to duplicate all that code in each JSP.

Q: I’m confused... this page heading says, “while we’re on the subject...” but I don’t see how directives have anything to do with pageContext and attributes.

A: They don’t, not really. We just said that to cover a nonexistent transition between two unrelated topics. We hoped nobody would notice, but NO...you just couldn’t let it go, could you?
Attributes to the page directive

Of the 13 page directive attributes in the JSP 2.0 spec, only four are covered on the exam. You do NOT have to memorize the entire list; just get a feel for what you can do. (We’ll look at the isELIgnored and the two error-related attributes in later chapters.)

POSSIBLY on the exam

- **import**: Defines the Java import statements that’ll be added to the generated servlet class. You get some imports for free (by default): java.lang (duh), javax.servlet, javax.servlet.http, and javax.servlet.jsp.

- **isThreadSafe**: Defines whether the generated servlet needs to implement the SingleThreadModel, which, as you know, is a Spectacularly Bad Thing. The default value is...”true”, which means, “My app is thread safe, so I do NOT need to implement SingleThreadModel, which I know is inherently evil.” The only reason to specify this attribute is if you need to set the attribute value to “false”, which means that you want the generated servlet to use the SingleThreadModel, but you never will.

- **contentType**: Defines the MIME type (and optional character encoding) for the JSP response. You know the default.

- **isELIgnored**: Defines whether EL expressions are ignored when this page is translated. We haven’t talked about EL yet; that’s coming in the next chapter. For now, just know that you might choose to ignore EL syntax in your page, and this is one of the two ways you can tell the Container.

- **isErrorPage**: Defines whether the current page represents another JSP’s error page. The default value is “false”, but if it’s true, the page has access to the implicit exception object (which is a reference to the offending Throwable). If false, the implicit exception object is not available to the JSP.

- **errorPage**: Defines a URL to the resource to which uncaught Throwables should be sent. If you define a JSP here, then that JSP will have an isErrorPage=”true” attribute in its page directive.

NOT on the exam

- **language**: Defines the scripting language used in scriptlets, expressions, and declarations. Right now, the only possible value is “java”, but the attribute is here because isn’t it just like those spec developers to be thinking of the future, when other languages might be used.

- **extends**: Defines the superclass of the class this JSP will become. You won’t use this unless you REALLY know what you’re doing—it overrides the class hierarchy provided by the Container.

- **session**: Defines whether the page will have an implicit session object. The default value is “true”.

- **buffer**: Defines how buffering is handled by the implicit out object (reference to the JspWriter).

- **autoFlush**: Defines whether the buffered output is flushed automatically. The default value is “true”.

- **info**: Defines a String that gets put into the translated page, just so that you can get it using the generated servlet’s inherited getServletInfo() method.

- **pageEncoding**: Defines the character encoding for the JSP. The default is “ISO-8859-1” (unless the contentType attribute already defines a character encoding, or the page uses XML Document syntax).
are scriptlets bad?

This is SUCH a nice chapter with a VERY lovely look at how to put Java code in a JSP, but, um, look at this company-wide memo I just got.

---

Interoffice Memo from the CTO

---

URGENT

Effective immediately, anyone caught using scriptlets, expressions, or declarations in their JSP code will be suspended without pay until such time as it can be determined whether the programmer was fully responsible or simply trying to maintain some OTHER idiot’s code.

If, in fact, the determination is made that the programmer is, in fact, responsible, the company will go ahead and, in fact, terminate the employee.

---

Rick Forester
Chief Technology Officer

---

"Remember: there is no "I" in TEAM."

"Write your code as if the next guy to maintain it is a homicidal maniac who knows where you live."

[Note to HR: we use “guy” in its non-gender specific form.]
Scriptlets considered harmful?

Is it true? Could there be a downside to putting all this Java into your JSP? After all, isn’t that the whole frickin’ POINT to a JSP? So that you write your Java in what is essentially an HTML page as opposed to writing HTML in a Java class?

Some people believe (OK, technically a lot of people including the JSP and Servlet spec teams) that it’s bad practice to put all this Java into your JSP.

Why? Imagine you’ve been hired to build a big web site. Your team includes a small handful of back-end Java programmers, and a huge group of “web designers”—graphic artists and page creators who use Dreamweaver and Photoshop to build fabulous-looking web pages. These are not programmers (well, except for the ones who still think HTML is “coding”).

Do YOU know Java?

Dude... do I LOOK like someone who would write code? I’m a high-paid Web Designer. DESIGNER. I’m an ARTIST, not a coder.

Aspiring actors working as web designers while waiting for their big showbiz break.
scripting is out there

There didn’t used to BE an alternative.

That means there are already mountains of JSP files brimming with Java code stuck in every conceivable spot in the page, nestled between scriptlet, expression, and declaration tags. It’s out there and there isn’t anything anyone can do to change the past. So that means you’ve got to know how to read and understand these elements, and how to maintain pages written with them (unless you’ve given the chance to massively refactor the app’s JSPs).

Secretly, we think there’s still a place for some of this—nothing beats a little Java in a JSP for quickly testing something out on your server. But for the most part, you don’t want to use this for real production pages.

The reason this is all on the exam is because the alternatives are still fairly new, so most of the pages out there today are still "old-school". For the time being, you still have to be able to work with it! At some point, when the new Java-free techniques hit critical mass, the objectives from this chapter will probably drop off the exam, and we’ll all breathe a collective sigh at the death of Java-in-JSPs.

But today is not that day.
EL: the answer to, well, everything.

Oh if only there were a way in a JSP to use simple tags that cause Java methods to run, without having to put actual Java code into the page.

Or almost everything. But certainly an answer to two big complaints about putting actual Java into a JSP:

1) Web page designers shouldn’t have to know Java.

2) Java code in a JSP is hard to change and maintain.

EL stands for “Expression Language”, and it became officially part of the spec beginning with JSP 2.0 spec. EL is nearly always a much simpler way to do some of the things you’d normally do with scriptlets and expressions.

Of course right now you’re thinking, “But if I want my JSP to use custom methods, how can I declare and write those methods if I can’t use Java?”

Ahhhh... writing the actual functionality (method code) is not the purpose of EL. The purpose of EL is to offer a simpler way to invoke Java code—but the code itself belongs somewhere else. That means in a regular old Java class that’s either a JavaBean, a class with static methods, or something called a Tag Handler. In other words, you don’t write method code into your JSP when you’re following today’s Best Practices. You write the Java method somewhere else, and call it using EL.
first look at **EL**

**Sneak peek at EL**

The entire next chapter is on EL, so we won't go into details here. The only reason we're covering it is because it's yet another kind of element (with its own syntax) that goes in a JSP, and the exam objectives for this chapter include recognizing everything that can go into a JSP!

**This EL expression:**

```
Pleas contact: ${applicationScope.mail}
```

**Is the same as this Java expression:**

```
Please contact: <%= application.getAttribute("mail") %>
```

Q: Not to be all negative, but I'm not sure I see an earth-shattering difference between the EL and the Java expression. Sure, it's a little shorter, but is that worth a whole new scripting language and JSP coding approach?

A: You SO haven't seen the full benefit of EL yet. The differences will become obvious in the next chapter when we dive in. But you must remember that to a Java programmer, EL is NOT necessarily a dramatic development advantage. In fact, to a Java programmer it simply means "one more thing (with its own syntax and everything) to learn, when, hey, I already KNOW Java..."

But it's not always about you. EL is much easier for a non-Java programmer to learn and get up to speed in. And for a Java programmer, it is still much easier to maintain a scriptless page.

Yes, it's still something to learn. It doesn't let web page designers completely off the hook, but you'll soon see that it's more intuitive and natural for a web designer to use EL. For now, in this chapter, you simply need to be able to recognize EL when you see it. And don't worry at this point about recognizing whether the expression itself is valid—all we care about now is that you can pick out an EL expression in a JSP page.
And just HOW do you expect me to get my programmers to stop using scripting elements in their JSPs?

Easy—you can put an element in the DD that disables all scripting elements!

Using <scripting-invalid>

It’s simple—you can make it invalid for a JSP to have scripting elements (scriptlets, Java expressions, or declarations) by putting a <scripting-invalid> tag in the DD:

```xml
<web-app ...
  ...
  <jsp-config>
    <jsp-property-group>
      <url-pattern>*.jsp</url-pattern>
      <scripting-invalid>true</scripting-invalid>
    </jsp-property-group>
  </jsp-config>
  ...
</web-app>
```

Watch out—you might have seen other books or articles show a page directive that disables scripting. In a draft version of the 2.0 spec, there was a page directive attribute:

```xml
<%@ page isScriptingEnabled="false" %>
```

but it was removed from the final spec!!

The only way to invalidate scripting now is through the <scripting-invalid> DD tag.
ignoring EL

You can choose to ignore EL

Yes, EL is a good thing that’s going to save the world as we know it. But sometimes you might want to disable it. Why?

Think back to when the assert keyword was added to the Java language with version 1.4. Suddenly the formerly unreserved and perfectly legal identifier “assert” meant something to the compiler. So if you had, say, a variable named assert, you were screwed. Except that J2SE version 1.4 came with assertions disabled by default. If you knew you were writing (or recompiling) code that didn’t use assert as an identifier, then you could choose to enable assertions.

So it’s kind of the same thing with disabling EL—if you happened to have template text (plain old HTML or text) in your JSP that included something that looked like EL ({$something}), you’d be in Big Trouble if you couldn’t tell the Container to just ignore anything that appears to be EL, and instead treat it like any other unprocessed text. Except there’s one big difference between EL and assertions:

EL is enabled by default!

If you want EL-looking things in your JSP to be ignored, you have to say so explicitly, either through a page directive or a DD element.

Putting <el-ignored> in the DD

```xml
<web-app ...
  ...
  <jsp-config>
    <jsp-property-group>
      <url-pattern>*.jsp</url-pattern>
      <el-ignored>true</el-ignored>
    </jsp-property-group>
    ...
  </jsp-config>
  ...
</web-app>
```

Using the isELIgnored page directive attribute

```xml
<%@ page isELIgnored="true" %>
```

The page directive attribute takes priority over the DD setting!

If there’s a conflict between the `<el-ignored>` setting in the DD and the `isELIgnored` page directive attribute, the directive always wins! That lets you specify the default behavior in the DD, but override it for a specific page using a page directive.

Watch out for the naming inconsistency!

The DD tag is `<el-ignored>`, so one might reasonably think that the page directive attribute would be `is:elIgnored`. But no, it wouldn’t be wrong if one jumped to the natural conclusion. The DD and the directive for ignoring EL do not match! Don’t be fooled by `<is:el-ignored>`.
But wait... there’s still another JSP element we haven’t seen: actions

So far, you’ve seen five different types of elements that can appear in a JSP: scriptlets, directives, declarations, Java expressions, and EL expressions. But we haven’t seen actions. They come in two flavors: standard and... not.

Standard Action:

```jsp
<jsp:include page="wickedFooter.jsp" />
```

Other Action:

```jsp
<c:set var="rate" value="32" />```

Although that’s misleading, because there are some actions that aren’t considered standard actions, but which are still part of a non-standard library. In other words, you’ll later learn that some of the non-standard (the objectives refer to them as custom) actions are... standard, but yet they still aren’t considered “standard actions”. Yes, that’s right—they’re standardized non-standard custom actions. Doesn’t that just clear it right up for you?

In a later chapter when we get to “using tags”, we’ll have a slightly richer vocabulary with which to talk about this in more detail, so relax. For now, all we care about is recognizing an action when you see it in a JSP!

Sharpen your pencil

Look at the syntax for an action, and compare it to the syntax for the other kinds of JSP elements. Then answer this:

1) What are the differences between an action element and a scriptlet?

2) How will you recognize an action when you see it?
### Evaluation Matrix

Think about what happens when each of these settings (or combination of settings) occur. You’ll see the answers when you turn the page, so do this one NOW.

#### EL Evaluation

<table>
<thead>
<tr>
<th>DD configuration</th>
<th>page directive</th>
<th>evaluated</th>
<th>ignored</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;el-ignored&gt;</td>
<td>isELIgnored</td>
<td></td>
<td></td>
</tr>
<tr>
<td>unspecified</td>
<td>unspecified</td>
<td></td>
<td></td>
</tr>
<tr>
<td>false</td>
<td>unspecified</td>
<td></td>
<td></td>
</tr>
<tr>
<td>true</td>
<td>unspecified</td>
<td></td>
<td></td>
</tr>
<tr>
<td>false</td>
<td>false</td>
<td></td>
<td></td>
</tr>
<tr>
<td>false</td>
<td>true</td>
<td></td>
<td></td>
</tr>
<tr>
<td>true</td>
<td>false</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Place a checkmark in the evaluated column if the settings would cause the EL expressions to be evaluated, OR place a checkmark in the ignored column if EL will be treated like other template text. No row will have two checkmarks, of course.

#### Scripting validity

<table>
<thead>
<tr>
<th>DD configuration</th>
<th>evaluated</th>
<th>ignored</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;scripting-invalid&gt;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>unspecified</td>
<td></td>
<td></td>
</tr>
<tr>
<td>true</td>
<td></td>
<td></td>
</tr>
<tr>
<td>false</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Place a checkmark in the evaluated column if the settings would cause the scripting expressions to be evaluated, OR place a checkmark in the ignored column if scripting will be treated like other template text.
### JSP Element Magnets

Match the JSP element with its label by placing the JSP snippet in the box with the label representing that element type. Remember, you’ll have Drag and Drop questions on the real exam similar to this exercise, so don’t skip it!

<table>
<thead>
<tr>
<th>JSP element type</th>
<th>JSP snippet</th>
</tr>
</thead>
<tbody>
<tr>
<td>directive</td>
<td><code>&lt;% Float one = new Float(42.5); %&gt;</code></td>
</tr>
<tr>
<td>declaration</td>
<td><code>&lt;% int y = 3; %&gt;</code></td>
</tr>
<tr>
<td>EL expression</td>
<td><code>&lt;%@ page import=&quot;java.util.&quot; %&gt;</code></td>
</tr>
<tr>
<td>scriptlet</td>
<td><code>&lt;% pageContext.getAttribute(&quot;foo&quot;) %&gt;</code></td>
</tr>
<tr>
<td>expression</td>
<td><code>email: ${applicationScope.mail}</code></td>
</tr>
<tr>
<td>action</td>
<td>you are here &gt; 323</td>
</tr>
</tbody>
</table>
JSP elements exercise

JSP Element Magnets: the Sequel
You know what they're called, but do you remember where they go in the generated servlet? Of course you do. But this is just a little reinforcement practice before we move on to a different chapter and topic. Put the element in the box corresponding to where that element's generated code will go in the servlet class file. Note that the magnet itself does not represent the actual code that will be generated.

public final class BasicCounter_jsp extends org.apache.jasper.runtime.HttpJspBase
    implements org.apache.jasper.runtime.JspSourceDependent {

    public void _jspService(HttpServletRequest request, HttpServletResponse response)
        throws java.io.IOException, ServletException {

    ...

    The order of these three magnets does not matter:

    ...

    }

    }

    <%= request.getAttribute("foo") %>
    servlet: ${applicationScope.mail}
    @ page import="java.util.*" %>
    % Float one = new Float(42.5); %>
    % int y = 3; %>

JSP elements answers

**JSP Element Magnets**

ANSWERS

```
<%@ page import="java.util.*" %>
```

directive

```
<! int y = 3;
```

declaration

```
email: ${applicationScope.mail}
```

EL expression

```
<% Float one = new Float(42.5); %>
```

scriptlet

```
<s pageContext.getAttribute("foo") %>
```

expression

```
<jsp:include file="foo.html" />
```

action

---

The word “expression” by itself means “scripting expression” or “scripting expression” NOT “EL expression”.

Of course the word “expression” is overloaded for JSP elements. If you see the word “expression” or “scripting expression” it means the same thing—an expression using Java language syntax:

```
<%= foo.getName()%>
```

The only time the word “expression” refers to EL is if you specifically see “EL” in the descriptions or labels. So, always assume that the default for the word “expression” is “scripting/Java expression”, not EL.
A page directive with an import attribute turns into a Java import statement.

```java
public final class BasicCounter_jsp extends org.apache.jasper.runtime.HttpJspBase
    implements org.apache.jasper.runtime.JspSourceDependent {

    <% int y = 3; %>

    public void _jspService(HttpServletRequest request, HttpServletResponse response) 
    throws java.io.IOException, ServletException {

        <% request.getAttribute("foo") %>

        <% Float one = new Float(42.5); %>

        email: $applicationScope.mail

    }

    NOTE: remember that the JSP code doesn’t actually GO into the servlet like this… it’s all translated into Java language code. This exercise is just to show you in what part of the generated class these elements GO, but we’re not showing you the actual generated code the elements are translated into. For example, the declaration goes from `int y = 3;` to just `int y = 3;` (Note: the order of these three things doesn’t matter.)
Given this DD element:

47. `<jsp-property-group>
48.  <url-pattern>*.jsp</url-pattern>
49.  <el-ignored>true</el-ignored>
50.  </jsp-property-group>

What does the element accomplish? (Choose all that apply.)

- A. All files with the specified extension mapping should be treated by the JSP container as well-formed XML files.
- B. All files with the specified extension mapping should have any Expression Language code evaluated by the JSP container.
- C. By default, all files with the specified extension mapping should NOT have any Expression Language code evaluated by the JSP container.
- D. Nothing, this tag is NOT understood by the container.
- E. Although this tag is legal, it is redundant, because the container behaves this way by default.

Which directives specify an HTTP response that will be of type “image/svg”?
(Choose all that apply.)

- A. `<%@ page type="image/svg" %>`
- B. `<%@ page mimeType="image/svg" %>`
- C. `<%@ page language="image/svg" %>`
- D. `<%@ page contentType="image/svg" %>`
- E. `<%@ page pageEncoding="image/svg" %>`
Given this JSP:

1. `<%@ page import="java.util.*" %>
2. `<html><body>` The people who like
3. `<%= request.getParameter("hobby") %>`
4. `are: <%= br %>`
5. `<% ArrayList al = (ArrayList) request.getAttribute("names"); %>`
6. `<% Iterator it = al.iterator(); %>`
7. `while (it.hasNext()) { %>`
8. `<%= it.next() %>`
9. `<% br %>`
10. `<% } %>`
11. `<% } %>`
12. `</body></html>`

Which types of code are used in this JSP? (Choose all that apply.)

- A. EL
- B. directive
- C. expression
- D. template text
- E. scriplet

Which statements about `jspInit()` are true? (Choose all that apply.)

- A. It has access to a `ServletConfig`.
- B. It has access to a `ServletContext`.
- C. It is only called once.
- D. It can be overridden.
mock exam

5 Which types of objects are available to the `jspInit()` method? (Choose all that apply.)
   - A. ServletConfig
   - B. ServletContext
   - C. JspServletConfig
   - D. JspServletContext
   - E. HttpServletRequest
   - F. HttpServletResponse

6 Given:
   `<%@ page isELIgnored="true" %>

   What is the effect? (Choose all that apply.)
   - A. Nothing, this `page` directive is NOT defined.
   - B. The directive turns off the evaluation of Expression Language code by the JSP container in all of the web application’s JSPs.
   - C. The JSP containing this directive should be treated by the JSP container as a well-formed XML file.
   - D. The JSP containing this directive should NOT have any Expression Language code evaluated by the JSP container.
   - E. This page directive will only turn off EL evaluation if the DD declares a `<el-ignored>true</el-ignored>` element with a URL pattern that includes this JSP.

7 Which statement concerning JSPs is true? (Choose one.)
   - A. Only `jspInit()` can be overridden.
   - B. Only `jspDestroy()` can be overridden.
   - C. Only `jspService()` can be overridden.
   - D. Both `jspInit()` and `jspDestroy()` can be overridden.
   - E. `jspInit()`, `jspDestroy()`, and `jspService()` can all be overridden.
Which JSP lifecycle step is out of order?

- A. Translate the JSP into a servlet.
- B. Compile servlet source code.
- C. Call \_jspService() 
- D. Instantiate the servlet class.
- E. Call jspInit() 
- F. Call jspDestroy()

Which are valid JSP implicit variables? (Choose all that apply)

- A. stream
- B. context
- C. exception
- D. listener
- E. application

Given a request with two parameters: one named "first" represents a user's first name and another named "last" represents his last name. Which JSP scriptlet code outputs these parameter values?

- A. `<% out.print(request.getParameter("first")); %>
  out.print(request.getParameter("last")); %>`
- B. `<% out.print(application.getInitParameter("first"));
  out.print(application.getInitParameter("last")); %>`
- C. `<% print(request.getParameter("first"));
  print(request.getParameter("last")); %>`
- D. `<% print(application.getInitParameter("first"));
  print(application.getInitParameter("last")); %>`
mock exam

Given:

11. Hello ${user.name}!
12. Your number is <c:out value="${user.phone}"/>
13. Your address is <jsp:getProperty name="user" property="addr"/>
14. <c if (user.isValid()) {You are valid!} }

Which statements are true? (Choose all that apply.)

- A. Lines 11 and 12 (and no others) contain examples of EL elements.
- B. Line 14 is an example of scriptlet code.
- C. None of the lines in this example contain template text.
- D. Lines 12 and 13 include examples of JSP standard actions.
- E. Line 11 demonstrates an invalid use of EL.
- F. All four lines in this example would be valid in a JSP page.

12. Which JSP expression tag will print the context initialization parameter named "javax.sql.DataSource"?

- A. `<%= application.getAttribute("javax.sql.DataSource") %>`
- B. `<%= application.getInitParameter("javax.sql.DataSource") %>`
- C. `<%= request.getParameter("javax.sql.DataSource") %>`
- D. `<%= contextParam.get("javax.sql.DataSource") %>`

13. Which statements about disabling scripting elements are true? (Choose all that apply.)

- A. You can’t disable scripting via the DD.
- B. You can only disable scripting at the application level.
- C. You can disable scripting programmatically by using the `isScriptingEnabled` page directive attribute.
- D. You can disable scripting via the DD by using the `<scripting-invalid>` element.
In sequence, what are the Java types of the following JSP implicit objects:
application, out, request, response, session?

- A. `java.lang.Throwable`
  `java.lang.Object`
  `java.util.Map`
  `java.util.Set`
  `java.util.List`

- B. `javax.servlet.ServletConfig`
  `java.lang.Throwable`
  `java.lang.Object`
  `javax.servlet.jsp.PageContext`
  `java.util.Map`

- C. `javax.servlet.ServletContext`
  `javax.servlet.jsp.JspWriter`
  `javax.servlet.HttpServletRequest`
  `javax.servlet.HttpServletResponse`
  `javax.servlet.http.HttpSession`

- D. `javax.servlet.ServletContext`
  `java.io.PrintWriter`
  `javax.servlet.ServletConfig`
  `java.lang.Exception`
  `javax.servlet.RequestDispatcher`

Which is an example of the syntax used to import a class in a JSP?

- A. `<%@ page import="java.util.Date" %>`
- B. `<%@ page import="java.util.Date" %>`
- C. `<%@ page import="java.util.Date" %>`
- D. `<% import java.util.Date; %>`
- E. `<%@ import file="java.util.Date" %>`
Given this DD element:

1. `<jsp-property-group>
2. <url-pattern>*.jsp</url-pattern>
3. <el-ignored>true</el-ignored>
4. </jsp-property-group>

What does the element accomplish? (Choose all that apply.)

- A. All files with the specified extension mapping should be treated by the JSP container as well-formed XML files.
- B. All files with the specified extension mapping should have any Expression Language code evaluated by the JSP container.
- C. By default, all files with the specified extension mapping should NOT have any Expression Language code evaluated by the JSP container.
- D. Nothing, this tag is NOT understood by the container.
- E. Although this tag is legal, it is redundant, because the container behaves this way by default.

Which directives specify an HTTP response that will be of type “image/svg”?

(Choose all that apply.)

- A. `<%@ page type="image/svg" %>`
- B. `<%@ page mimetype="image/svg" %>`
- C. `<%@ page language="image/svg" %>`
- D. `<%@ page content-type="image/svg" %>`
- E. `<%@ page pageEncoding="image/svg" %>`
Given this JSP:

1. `<%@ page import="java.util.*" %>`
2. `<html><body>` The people who like
3. `<%= request.getParameter("hobby") %>`
4. `<a>`
5. `<% ArrayList al = (ArrayList) request.getAttribute("names"); %>`
6. `<% Iterator it = al.iterator(); %>`
7. `while (it.hasNext()) { %>`
8. `&lt;%= it.next() %&gt;`
9. `<br>`
10. `<% } %>`
11. `</body></html>`

Which types of code are used in this JSP? (Choose all that apply.)

- A. EL
- B. directive
- C. expression
- D. template text
- E. scriptlet

Which statements about `jspInit()` are true? (Choose all that apply.)

- A. It has access to a `ServletContext`
- B. It has access to a `ServletConfig`
- C. It is only called once.
- D. It can be overridden.
mock answers

5 Which types of objects are available to the jspInit() method? (Choose all that apply.)

- ServletConfig
- ServletContext
- JspServletConfig
- JspServletContext
- HttpServletRequest
- HttpServletResponse

6 Given:

```jsp
<%@ page isELIgnored="true" %>
```

What is the effect? (Choose all that apply.)

- A. Nothing, this page directive is NOT defined.
- B. The directive turns off the evaluation of Expression Language code by the JSP container in all of the web application’s JSPs.
- C. The JSP containing this directive should be treated by the JSP container as a well-formed XML file.
- D. The JSP containing this directive should NOT have any Expression Language code evaluated by the JSP container.
- E. This page directive will only turn off EL evaluation if the DD declares a <el-ignored>true</el-ignored> element with a URL pattern that includes this JSP.

7 Which statement concerning JSPs is true? (Choose one.)

- A. Only jspInit() can be overridden.
- B. Only jspDestroy() can be overridden.
- C. Only _jspService() can be overridden.
- D. Both jspInit() and jspDestroy() can be overridden.
- E. jspInit(), jspDestroy(), and _jspService() can all be overridden.
Which JSP lifecycle step is out of order?

- A. Translate the JSP into a servlet.
- B. Compile servlet source code.
- C. Call _jspService().
- D. Instantiate the servlet class.
- E. Call jspInit().
- F. Call jspDestroy().

Which are valid JSP implicit variables? (Choose all that apply)

- A. stream
- B. context
- C. exception
- D. listener
- E. application

Given a request with two parameters: one named “first” represents a user’s first name and another named “last” represents his last name.

Which JSP scriptlet code outputs these parameter values?

- Option A uses the “out” implicit object and its println() method.
- Options B, C, and D don’t exist as implicit objects created by the container for JSPs.

(using JSP v2.0 section 1.8.3)
mock answers

Given:
11. Hello ${user.name}!
12. Your number is <:out value="${user.phone}"/>
13. Your address is <jsp:getProperty name="user" property="addr" />
14. <% if (user.isValid()) { %><p>You are valid!</p><% } %> 
Which statements are true? (Choose all that apply.)
- Option C is incorrect because all four lines include template text.
- Option E is incorrect because the EL in line 11 is valid.

12. Which JSP expression tag will print the context initialization parameter named “javax.sql.DataSource”?
- Option B shows the correct use of the application implicit object.
- Option C is incorrect because the <jsp:getInitParameter> element allows you to disable scripting in selective JSPs by specifying URL patterns to be disabled.

13. Which statements about disabling scripting elements are true? (Choose all that apply.)
- Option D is incorrect because line 12 does not include a JSP standard action.
- Option E is incorrect because the EL in line 11 is valid.
In sequence, what are the Java types of the following JSP implicit objects:

- application, out, request, response, session?

- A. java.lang.Throwable
  - java.lang.Object
  - java.util.Map
  - java.util.Set
  - java.util.List

- B. javax.servlet.ServletConfig
  - java.lang.Throwable
  - java.lang.Object
  - javax.servlet.jsp.PageContext
  - java.util.Map

- C. javax.servlet.ServletContext
  - javax.servlet.jsp.JspWriter
  - javax.servlet.HttpServletRequest
  - javax.servlet.HttpServletResponse
  - javax.servlet.http.HttpSession

- D. javax.servlet.HttpServletRequest
  - java.io.PrintWriter
  - javax.servlet.ServletContext
  - java.lang.Exception
  - javax.servlet.RequestMappingDispatcher

Which is an example of the syntax used to import a class in a JSP?

- A. <% page import="java.util.Date" %>
- B. <%= page import="java.util.Date" %>
- C. <% page import="java.util.Date" %>
- D. <% import java.util.Date; %>
- E. <%= import file="java.util.Date" %>

---

Option C shows the Java type of each implicit object.

Options A & D are invalid because only Java statements may be included within `<% ... %> tags.

Option C is the only example that shows the correct syntax.

Option E is invalid because there is no import directive.
Lose the scripting. Do your web page designers really have to know Java? Is that fair? Do they expect server-side Java programmers to be, say, graphic designers? And even if it’s just you on the team, do you really want a pile of bits and pieces of Java code in your JSPs? Can you say, “maintenance nightmare”? Writing scriptless pages is not just possible, it’s become much easier and more flexible with the new JSP 2.0 spec, thanks to the new Expression Language (EL). Patterned after JavaScript and XPATH, web designers feel right at home with EL, and you’ll like it too (once you get used to it). But there are some traps... EL looks like Java, but isn’t. Sometimes EL behaves differently than if you used the same syntax in Java, so pay attention!
Official Sun Exam Objectives

Building JSP pages using the Expression Language (EL) and Standard Actions

7.1 Write a code snippet using top-level variables in the EL. This includes the following implicit variables: pageScope, requestScope, sessionScope, and applicationScope; param and paramValues; header and headerValues; cookies; and initParam.

7.2 Write a code snippet using the following EL operators: property access (the . operator), collection access (the [] operator).

7.3 Write a code snippet using the following EL operators: arithmetic operators, relational operators, and logical operators.

7.4 For EL functions: Write a code snippet using an EL function; identify or create the TLD file structure used to declare an EL function; and identify or create a code example to define an EL function.

8.1 Given a design goal, create a code snippet using the following standard actions: jsp:useBean (with attributes: id, scope, type, and class), jsp:getProperty, and jsp:setProperty (with all attribute combinations).

8.2 Given a design goal, create a code snippet using the following standard actions: jsp:include, jsp:forward, and jsp:param.

6.7 Given a specific design goal for including a JSP segment in another page, write the JSP code that uses the most appropriate inclusion mechanism (the include directive or the <jsp:include> standard action).

Coverage Notes:

All of the objectives in this section are covered completely in this chapter. And it’s a big one.
Take your time in this chapter; there’s a lot of picky details to go through.

In this chapter, we cover BOTH include mechanisms: <jsp:include> from objective 8.2, and the include page directive from objective 6.7 (most of the objectives in section 6 were covered in the previous chapter on JSPs).
Our MVC app depends on attributes

Remember in the original MVC beer app, the Servlet controller talked to the model (Java class with business logic), then set an attribute in the request scope before forwarding to the JSP view.

The JSP had to get the attribute from the request scope, and use it to render a response to send back to the client. Here’s a quick, simplified look at how the attribute goes from controller to view (just imagine the servlet talks to the model):

**Servlet (controller) code**

```java
public void doPost(HttpServletRequest request, HttpServletResponse response)
    throws IOException, ServletException {

    String name = request.getParameter("username");
    request.setAttribute("name", name);

    RequestDispatcher view = request.getRequestDispatcher("/result.jsp");
    view.forward(request, response);
}
```

**JSP (view) code**

```html
<html>
<body>
Hello
<title>
<!-- request.getAttribute("name") --&gt;
</title>
</body>
</html>
```

You are here

*scriptless JSPs*
**non-String attributes**

**But what if the attribute is not a String, but an instance of Person?**

And not just a Person, but a Person with a “name” property.

We’re using the term “property” in the non-enterprise JavaBean way—the Person class has a `getName()` and `setName()` method pair, which in the JavaBean spec means Person has a property called “name”. Don’t forget that the “name” property means a change in case for the first letter, “n”. In other words, the name of the property is what you get when you strip off the prefix “get” and “set”, and make the first character after that lower case. So, `getName/setName` becomes `name`.

**Servlet code**

```java
public void doPost(HttpServletRequest request, HttpServletResponse response) throws IOException, ServletException {
    foo.Person p = new foo.Person();
    p.setName("Evan");
    request.setAttribute("person", p);
    RequestDispatcher view = request.getRequestDispatcher("result.jsp");
    view.forward(request, response);
}
```

**JSP code**

```html
<html>
<body>
   Person is: <%= request.getAttribute("person") %>
</body>
</html>
```

*What we WANT:

Person is: Evan

*What we GOT:

Person is: foo.Person@512666

"Oh... obviously the expression just called the attribute’s default `toString()` method..."

"We’ll talk about JavaBeans in a few pages, but for now, just know that it’s a plain old Java class that has getters and setters that follow a naming convention."
We need more code to get the Person’s name

Sending the result of `getAttribute()` to print/write statement doesn’t give us what we want—it just runs the object’s `toString()` method. And since class Person doesn’t override its inherited `Object.toString()`, well, you know what happens. But we want to print the Person’s name.

**JSP code**

```html
<% foo.Person p = (foo.Person) request.getAttribute("person"); %>
Person is: <%= p.getName() %>
```

**OR using an expression**

```html
Person is: <%= ((foo.Person) request.getAttribute("person")).getName() %> 
```

**What we GOT:**

![Image of output]

Person is: Evan

**But then we remember that MEMO...**

The one that can be summarized as “Use Scripting and Die”

We need a different approach.
JavaBean standard actions

Person is a JavaBean, so we'll use the bean-related standard actions

With a couple of standard actions, we can eliminate all the scripting code in our JSP (remember: scripting code includes declarations, scriptlets, and expressions) and still print out the value of the person attribute’s name property. Don’t forget that name is not an attribute—only the person object is an attribute. The name property is simply the thing returned from a Person’s getName() method.

Without standard actions (using scripting)

```html
<html><body>
<%! foo.Person p = (foo.Person) request.getAttribute("person"); %>
Person is: <%= p.getName() %>
</body></html>
```

With standard actions (no scripting)

```html
<html><body>
<jsp:useBean id="person" class="foo.Person" scope="request" />
Person created by servlet: <jsp:getProperty name="person" property="name" />
</body></html>
```
Deconstructing `<jsp:useBean>` and `<jsp:getProperty>`

All we really wanted was the functionality of `<jsp:getProperty>` because we wanted only to display the value of the person’s “name” property. But how does the Container know what “person” means? If we had only the `<jsp:getProperty>` tag in the JSP, it’s almost like using an undeclared variable—the name “person”. The Container usually has no idea what you’re talking about, unless you FIRST put a `<jsp:useBean>` into the page. The `<jsp:useBean>` is a way of declaring and initializing the actual bean object you’re using in `<jsp:getProperty>`.

**Declare and initialize a bean attribute with `<jsp:useBean>`**

- `<jsp:useBean id="person" class="foo.Person" scope="request" />`
  - Identifies the standard action.
  - Declares the identifier for the bean object. This corresponds to the name used when the servlet code said `request.setAttribute("person", p);`.
  - Identifies the class type (fully-qualified, of course) for the bean object.
  - Identifies the attribute scope for this bean object.

**Get a bean attribute’s property value with `<jsp:getProperty>`**

- `<jsp:getProperty name="person" property="name" />`
  - Identifies the standard action.
  - Identifies the actual bean object. This will match the `id` value from the `<jsp:useBean>` tag.
  - Identifies the property name (in other words, the thing with the getter and setter in the bean class).
  - Note: this “name” property has nothing to do with the name “person” part of this tag. The property is called “name” simply because of the way the Person class is defined.
<jsp:useBean>

**<jsp:useBean> can also CREATE a bean!**

If the `<jsp:useBean>` can’t find an attribute object named “person”, it can make one! It’s kind of the way `request.getSession()` (or `getSession(true)`) works—it first searches for an existing thing, but if it doesn’t find one, it creates one.

Look at the code from the generated servlet, and you’ll see what’s happening—there’s an if/else in there! It checks for a bean based on the values of `id` and `scope` in the tag, and if it doesn’t get one, it makes an instance of the class specified in `class`, assigns the object to the `id` variable, then sets it as an attribute in the `scope` you defined in the tag.

**This tag**

```
<jsp:useBean id="person" class="foo.Person" scope="request" />
```

**Turns into this code in the _jspService() method**

```
foo.Person person = null;

synchronized (request) {

    person = (foo.Person) _jspx_page_context.getAttribute("person", PageContext.REQUEST_SCOPE);

    if (person == null) {

        person = new foo.Person();

        _jspx_page_context.setAttribute("person", person, PageContext.REQUEST_SCOPE);

    }

    // other code...

}
```

Declare a variable based on the value of `id`. This variable is what lets other parts of your JSP (including other bean tags) refer to that variable.

Tries to get the attribute at the scope you defined in the tag, and assigns the result to the `id` variable.

BUT, if there was NOT an attribute with that name at that scope...

Make one, and assign it to the `id` variable.

Finally, set the new object as an attribute at the scope you defined.
**scriptless JSPs**

You can use `<jsp:setProperty>`

But you already knew that there’s a `get` there’s usually a `set`. The `<jsp:setProperty>` tag is the third and final bean standard action. It’s simple to use:

```jsp
<jsp:useBean id="person" class="foo.Person" scope="request" />
<jsp:setProperty name="person" property="name" value="Fred" />
```

That’s worse! NOW it means that if the bean already existed, my JSP will reset the existing bean’s property value! I want to set the property on only the NEW bean(s)...

---

Chapter 8. Script-free pages

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: O'Reilly

Prepared for Stephen Goss, Safari ID: stephengoss@gmx.net

Redistribution or other use that violates the fair use privilege under U.S. copyright laws (see 17 USC107) or that otherwise violates the Safari Terms of Service is strictly prohibited.
<jsp:useBean> can have a body!</jsp:useBean>

If you put your setter code `<jsp:setProperty>` inside the body of `<jsp:useBean>`, the property setting is conditional. In other words, the property values will be set only if a new bean is created. If an existing bean with that scope and id are found, the body of the tag will never run, so the property won’t be reset from your JSP code.

```jsp
<jsp:useBean id="person" class="foo.Person" scope="page">
    <jsp:setProperty name="person" property="name" value="Fred" />
</jsp:useBean>
```

Q: Why didn’t they just let you specify arguments to the constructor of the bean? Why do you have to go through the extra trouble of setting values anyway?

A: The simple answer is this: beans can’t “HAVE constructors with arguments! Well, as a Java class, they can, but when an object is going to be treated as a bean, Bean Law states that ONLY the bean’s public, no-arg constructor will be called. End of story. In fact if you do NOT have a public no-arg constructor in your bean class, this whole thing will fail anyway.

Q: What the heck is Bean Law?

A: The law according to the creakingly-ancient JavaBeans specification. We’re talking JavaBeans—NOT Enterprise JavaBeans (EJB) which is completely unrelated. (Go figure.) The plain old non-enterprise JavaBeans spec defines what it takes for a class to be a JavaBean. Although the spec actually gets pretty complex, the only things you need to know for using beans with JSP and servlets are these few rules (we’re showing only those that apply to what we’re doing with servlets and JSPs):

1) You MUST have a public, no-arg constructor.
2) You MUST name your public getter and setter methods starting with “get” (or “is” for a boolean) and “set”, followed by the same word. (e.g. `getFoo()`, `setFoo()`) The property name is derived from stripping off the “get” and “set”, and changing the first character of what’s left to lowercase.
3) The setter argument type and the getter return type MUST be identical. This defines the property type.
4) The property name and type are derived from the getters and setters and NOT from a member in the class. For example, just because you have a private int foo variable does NOT mean a thing in terms of properties. You can name your variables whatever you like. The “foo” property name comes from the method. In other words, you have a property simply because you have a getter and setter. How you implement them is up to you.
5) For use with JSPs, the property type SHOULD be a type that is either a String or a primitive. If it isn’t, it can still be a legal bean, but you won’t be able to rely only on standard actions, and you might have to use scripting.
Generated servlet when `<jsp:useBean>` has a body

It’s simple. The Container puts the extra property-setting code inside the `if` test.

```java
Code in _jspService() WITH the `<jsp:useBean> body

foo.Person person = null; ← Declare the reference variable
person = (foo.Person) _jspx_page_context.getAttribute("person", PageContext.PAGE_SCOPE);
if (person == null){ ← If there isn’t one, make a new instance.
    person = new foo.Person();
    _jspx_page_context.setAttribute("person", person, PageContext.PAGE_SCOPE);

    org.apache.jasper.runtime.JspRuntimeLibrary.introspectHelper(
        _jspx_page_context.findElement("person"), "name", "Fred", null, null, false);

    You were expecting
    person.setName("Fred");
    but that’s what this code does. Except it uses a
generic property-setting method that takes the
attribute, the property, and the value as arguments.
The end result is still the same; ultimately it invokes
setName() on the Person object.
(Remember you aren’t expected to know the Tomcat
implementation code...only the end result.)
```
polymorphic references

Can you make polymorphic bean references?

When you write a <jsp:useBean>, the class attribute determines the class of the new object (if one is created). It also determines the type of the reference variable used in the generated servlet.

The way it is NOW in the JSP

<jsp:useBean id="person" class="foo.Person" scope="page" />

Generated servlet

```java
foo.Person person = null;
// code to get the person attribute
if (person == null)
    person = new foo.Person();
```

But... what if we want the reference type to be different from the actual object type? We'll change the Person class to make it abstract, and make a concrete subclass Employee.

Imagine we want the reference type to be Person, and the new object type to be Employee.

```java
package foo;
public abstract class Person {
    private String name;
    public void setName(String name) {
        this.name = name;
    }
    public String getName() {
        return name;
    }
}
```

```java
package foo;
public class Employee extends Person {
    private int empID;
    public void setEmpID(int empID) {
        this.empID = empID;
    }
    public int getEmpID() {
        return empID;
    }
}
```
Adding a type attribute to `<jsp:useBean>`

With the changes we just made to the Person class, we’re in trouble if the attribute can’t be found:

**Our original JSP**

```jsp
<jsp:useBean id="person" class="foo.Person" scope="page"/>
```

**Has this result**

java.lang.InstantiationException: foo.Person

**Because the Container tries to:**

```java
new foo.Person();
```

We need to make the `reference` variable type Person, and the `object` an instance of class Employee. Adding a type attribute to the tag lets us do that.

**Our new JSP with a type**

```jsp
<jsp:useBean id="person" type="foo.Person" class="foo.Employee" scope="page"/>
```

**Generated servlet**

```java
foo.Person person = null;
// code to get the person attribute
if (person == null) {
    person = new foo.Employee();
    ...
```

Type can be a class type, abstract type, or an interface—anything that you can use as a declared reference type for the class type of the bean object. You can’t violate Java typing rules, of course. If the `class` type can’t be assigned to the `reference` type, you’re screwed. So that means the `class` must be a subclass or concrete implementation of the `type`.
type without class

Using type without class

What happens if we declare a type, but not a class?

Does it matter if the type is abstract or concrete?

JSP

```jsp
<jsp:useBean id="person" type="foo.Person" scope="page"/>
```

Result if the person attribute already exists in “page” scope

It works perfectly.

Result if the person attribute does NOT exist in “page” scope

WON'T WORK!!

```java
java.lang.InstantiationException: bean person not found within scope
```

If type is used without class, the bean must already exist.

If class is used (with or without type) the class must NOT be abstract, and must have a public no-arg constructor.

Q: In your example, “foo.Person” is an abstract type, so of COURSE it can’t be instantiated. What if you change the type to “foo.Employee”? Will it use the type for both the reference AND the object type?

A: NO! It never works. If the Container discovers that the bean doesn’t exist, and it sees only a type attribute without a class, it knows that you’ve given it only HALF of what it needs—the reference type but not the object type. In other words, you haven’t told it what to make a new instance of!

There is no fallback rule that says, “If you can’t find the object, go ahead and use the type for BOTH the reference and the object.” No, that is NOT how it works.

Bottom line: if you use type without class, you better make CERTAIN that the bean is already stored as an attribute, at the scope and with the id you put in the tag.
The scope attribute defaults to "page"

If you don’t specify a scope in either the `<jsp:useBean>` or `<jsp:getProperty>` tags, the Container uses the default of "page".

**This**

```jsp
<jsp:useBean id="person" class="foo.Employee" scope="page"/>
```

**Is the same as this**

```jsp
<jsp:useBean id="person" class="foo.Employee"/>
```

---

Don’t confuse type with class!

Check out this code:

```jsp
<jsp:useBean id="person" type="foo.Employee" class="foo.Person"/>
```

Be prepared to recognize that this will NEVER work! You’ll get a big fat:

org.apache.jasper.JasperException: Unable to compile class for JSP

foo.Person is abstract; cannot be instantiated

Person = new foo.Person();

Be SURE that you remember:

```
type == reference type
class == object type
```

Or to put it another way:

**type is what you DECLARE (can be abstract)**

**class is what you INSTANTIATE (must be concrete)**

```java
type x = new class()
```

Now, you’re probably thinking, “Well DUH—class is always a class while type doesn’t have to be—type can be an interface. So of COURSE they used “class” to represent things that must ALWAYS be a class, and “type” for things that can be interfaces as well.” And you’d be right. But you’re also thinking, “Of course, not EVERYTHING in the spec has the most intuitive and obvious name, so I better be sure.” Sometimes like security `<auth-constraint>`, the name of a thing is the opposite of what it actually is. But in this case, class is class, and type is... type.
bean-related standard actions exercise

BE the Container

Look at this standard action:

```jsp
<jsp:useBean id="person" type="foo.Employee" />
<jsp:setProperty name="person" property="name" value="Fred" />
</jsp:useBean>

Name is: <jsp:getProperty name="person" property="name" />
```

Now imagine that a servlet does some work and then forwards the request to the JSP that has the code above. Figure out what the JSP code above would do for each of the three different servlet code examples. (The answers are at the end of the chapter.)

1. What happens if the servlet code looks like:
   ```java
   foo.Employee p = new foo.Employee();
p.setName("Evan");
   request.setAttribute("person", p);
   ```

2. What happens if the servlet code looks like:
   ```java
   foo.Person p = new foo.Person();
p.setName("Evan");
   request.setAttribute("person", p);
   ```

3. What happens if the servlet code looks like:
   ```java
   foo.Employee p = new foo.Employee();
p.setName("Evan");
   request.setAttribute("person", p);
   ```

356 chapter 8
Chapter 8. Script-free pages

I just thought of something... suppose we aren't using a server controller, and the HTML form action goes straight to the JSP... is there a way I can use the request parameters to set a bean property, WITHOUT using scripting?

Going straight from the request to the JSP without going through a servlet...

Imagine this is our form:

```html
<html><body>
<form action="TestBean.jsp">
  name: <input type="text" name="userName">
  ID#: <input type="text" name="userID">
  <input type="submit">
</form>
</body></html>
```

We know we can do it with a combination of standard actions and scripting:

```jsp
<jsp:useBean id="person" type="foo.Person" class="foo.Employee" />
\% person.setName(request.getParameter("userName")); \%
</jsp:useBean>
```

We can even do it with scripting INSIDE a standard action:

```jsp
<jsp:useBean id="person" type="foo.Person" class="foo.Employee" />
\% jsp:setProperty name="person" property="name" value="\% request.getParameter("userName") \%" / \%
</jsp:useBean>
```

Yes, you ARE setting an expression INSIDE the body of a `<jsp:useBean>` tag.

And yes, it DOES look bad.
The **param** attribute to the rescue

It’s so simple. You can send a request parameter straight into a bean, without scripting, using the **param** attribute.

**The **param** attribute lets you set the value of a bean property to the value of a request parameter. JUST by naming the request parameter!**

**Inside TestBean.jsp**

```jsp
<jsp:useBean id="person" type="foo.Person" class="foo.Employee"/>
<jsp:setProperty name="person" property="name" param="userName"/>
</jsp:useBean>

<html><body>
<form action="TestBean.jsp">
    name: <input type="text" name="userName">
    ID#: <input type="text" name="userID">
    <input type="submit">
</form>
</body></html>
```

The param value ÒuserNameÓ comes from the name attribute of the form’s input field.
**But wait! It gets even better...**

And all you have to do is make sure your form **input field name** (which becomes the request parameter name) is the same as the **property name** in your bean. Then in the `<jsp:setProperty>` tag, you don’t have to specify the **param** attribute. If you name the **property** but don’t specify a **value or param**, you’re telling the Container to get the value from a request parameter with a matching name.

**If we change the HTML so that the input field name matches the property name:**

```html
<form action="TestBean.jsp">
    name: <input type="text" name="name" />
    ID: <input type="text" name="userID" />
    <input type="submit" />
</form>
</body></html>
```

**We get to do THIS**

```jsp
<jsp:useBean id="person" type="foo.Person" class="foo.Employee">
    <jsp:setProperty name="person" property="name" />
</jsp:useBean>
```

If the request parameter name matches the bean property name, you don’t need to specify a value in the `<jsp:setProperty>` tag for that property.
properties and request parameters

If you can stand it, it gets even BETTER...

Watch what happens if you make ALL the request parameter names match
the bean property names. The person bean (which is an instance of foo.
Employee) actually has two properties—name and emplD.

If we change the HTML again

abstract foo.Person
String getName()
void setName(String)

foo.Employee
int getEmpID()
void setEmpID(int)

We get to do this

<jsp:useBean id="person" type="foo.Person" class="foo.Employee"/>
<jsp:setProperty name="person" property="*"/>

I want you to iterate
through the request parameters,
and find any that match this bean's
property names, and set the VALUE of
the matching properties equal to the
value of the corresponding request
parameter...

Oh sure... make ME do all
the work. I have to look at
the bean class geters and
setters to figure out the bean
properties, then match that to
the parameter names.

JSP

Container

chapter 8
Bean tags convert primitive properties automatically

If you’re familiar with JavaBeans from any earlier lifetime, this is no surprise to you. JavaBean properties can be anything, but if they’re Strings or primitives, all the coercing is done for you. That’s right—you don’t have to do the parsing and conversion yourself.

If we make the type Employee (instead of Person)

```html
<html><body>
<jsp:useBean id="person" type="foo.Employee" class="foo.Employee" />
<jsp:setProperty name="person" property="name" />
</jsp:useBean>

Person is: <jsp:getProperty name="person" property="name" />
ID is: <jsp:getProperty name="person" property="empID" />
</body></html>
```

It all works

The `<jsp:setProperty>` action takes the String request parameter, converts it to an int, and passes that int to the bean’s setter method for that property.

The generated servlet will say:

```java
Employee person = new Employee();
```

... instead of:

```java
Person person = new Employee();
```
Q: OK, I'm thinking that the Container code is doing some kind of Integer.parseInt("343"), so wouldn't you get a NumberFormatException even if the user doesn't type in something that can be parsed to an int? Like, what if the user types "three" in the employee ID field?

A: Good catch. Yes, something will definitely go wrong if the request parameter for the empID property can't be parsed into an int. You need to validate the contents of that field, to make sure it contains only numeric characters. You could send the form data to a servlet first, instead of sending it straight to the JSP. But if you're committed to going from the form straight to the JSP, and you don't want scripting, just use JavaScript in the HTML form to check the field before sending the request. If you're not familiar with JavaScript (which of course has virtually NOTHING to do with Java), it's a simple scripting language that's processed on the client side. In other words, by the browser. A quick Google search on "JavaScript validate input field" should turn up some scripts you can use to stop users from entering, say, anything but numbers into an input field.

Q: If a bean property doesn't have to be a String or a primitive, then HOW can you set the property without scripting? The value attribute of the tag is always a String, right?

A: It is possible (but potentially a "lot" of extra work) to create a special class, called a custom property editor, that supports the bean. It takes your String value and figures out how to parse that into something that can be used to set a more complex type. This is part of the JavaBeans spec, though, not the JSP spec. Also, if the value attribute in the <jsp:setProperty> tag is an expression rather than a String literal, then if that expression evaluates to an object that's compatible with bean property type, then it will probably work. If you pass in an expression that evaluates to a Dog, for example, the Person bean's setDog(Dog) method will be called. But think about it—this means the Dog object must already exist. Anyway, you're way better off NOT trying to construct new things in your JSP. Trying to get away with constructing and setting even marginally complex data types is gonna be tough without scripting. (And none of that is on the exam.)

Automatic String-to-primitive conversion does NOT work if you use scripting!! It fails even if an expression is INSIDE the <jsp:setProperty> tag.

Q: These all work!

A: This does NOT work!

if you use the <jsp:setProperty> standard action tag with the property wildcard, OR just a property name without a value or param attribute (which means the property name matches the request parameter name), OR you use a param attribute to indicate the request parameter whose value should be assigned to the bean's property. OR you type a literal value, the automatic conversion from String to int works. Each of these examples converts automatically:

```java
<jsp:setProperty name="person" property="*" />
<jsp:setProperty name="person" property="empID" />
<jsp:setProperty name="person" property="empID" value="343" />
<jsp:setProperty name="person" property="empID" param="empID" />
```

BUT... if you use scripting, the automatic conversion does NOT work:

```java
<%= request.getParameter("empID") %>
```

org.apache.jasper.JasperException: Unable to compile class for JSP
Generated servlet error:
setEmpID(int) in foo.Employee cannot be applied to (java.lang.String)
Person.setEmpID(request.getParameter("empID"));
The bean standard action tags are more natural to a non-programmer.

Once again, the benefit of using tags over scripting is more about the web page designers than about you (the Java programmer). Although even Java programmers find that tags are easier to maintain than hard-coded Java scripting elements. With the bean-related tags, the designer needs only the basic identification info (attribute name, scope, and property name). True, they do have to know the fully-qualified class name, but as far as the web page designer knows—it’s just a name with dots (.) in it. The web designer doesn’t need any knowledge of what’s really behind it, and they can think of beans as simply records with fields. You tell the designers the record (the class and the identifier) and the fields (the properties).

Still, the bean standard actions aren’t as elegant as they could be.

And that’s why this isn’t the end of the story on scriptless pages. Read on...
**But what if the property is something OTHER than a String or primitive?**

We know how easy it is to print an attribute when the attribute itself is a String. Then we made an attribute that was a non-String object (a Person bean instance). But we didn’t want to print the attribute (person)—we wanted to print a property of the attribute (in our example, the person’s name and empID). That worked fine, because the standard actions can handle String and primitive properties. So, we know that standard actions can deal with an attribute of any type, as long as all the attribute’s properties are Strings or primitives.

But what if they’re not? What if the bean has a property that is not a String or primitive? What if the property is yet another Object type? An Object type with properties of its own?

*What if what we really want is to print a property of that property?*

- Person has a String “name” property.
- Person has a Dog “dog” property.
- Dog has a String “name” property.

**What if we want to print the name of the Person’s dog?**

**Servlet code**

```java
public void doPost(HttpServletRequest request, HttpServletResponse response)
        throws IOException, ServletException {

    foo.Person p = new foo.Person();
    p.setName("Evan");

    foo.Dog dog = new foo.Dog();
    dog.setName("Spika");
    p.setDog(dog);

    request.setAttribute("person", p);

    RequestDispatcher view = request.getRequestDispatcher("result.jsp");
    view.forward(request, response);
}
```

364 chapter 8
Trying to display the property of the property

We know we can do it with scripting, but can we do it with the bean standard actions? What happens if we put “dog” as the property in the `<jsp:getProperty>` tag?

**Without standard actions (using scripting)**

```html
<html><body>
<% ((foo.Person) request.getAttribute("person")).getDog().getName() %>
</body></html>
```

**With standard actions (no scripting)**

```html
<html><body>
<jsp:useBean id="person" class="foo.Person" scope="request" />
Dog's name is: <jsp:getProperty name="person" property="dog" />
</body></html>
```

**What we WANT**

Dog’s name is: Spike

**What we GOT**

Dog’s name is: foo.Dog@799338

All we got was the result of Dog's toString() method

There’s no combination of the bean standard actions that’ll work given the original servlet code, because the Dog is not an attribute! Dog is a property of the attribute, so you can display the Dog, but you can’t navigate to the name property of the Dog property of the Person attribute.

The `<jsp:getProperty>` lets you access only the properties of the bean attribute. There’s no capability for nested properties, where you want a property of a property, rather than a property of the attribute.

scriptless JSPs
**EL to the rescue**

**Expression Language (EL) saves the day!**

Yes, just in time to save us, the JSP Expression Language (EL) was added to the JSP 2.0 spec, releasing us from the tyranny of scripting. Look how beautifully simple our JSP is now...

**JSP code without scripting, using EL**

```html
<html><body>
  Dog’s name is: ${person.dog.name}
</body></html>
```

This:

```java
${person.dog.name}
```

Replaces this:

```java
<%=
  ((foo.Person) request.getAttribute("person")).getDog().getName() %>
```

---

**You don’t need to know EVERYTHING about EL.**

The exam doesn’t expect you to be a complete EL being. Everything you might typically use, or be tested on, is covered in the next few pages. So, if you want to study the EL spec, knock yourself out. Just so you’re clear that WE didn’t tell you to do that.

---

366  chapter 8
Deconstructing the JSP Expression Language (EL)

The syntax and range of the language are dirt simple. The tricky part is that some of EL looks like Java, but behaves differently. You’ll see when we get to the [] operator in a moment. So you’ll find things that wouldn’t work in Java but will work in EL, and vice-versa. Just don’t try to map Java language/syntax rules onto EL, and you’ll be fine. For the next few pages, think of EL as a way to access Java objects without using Java.

EL expressions are ALWAYS within curly braces, and prefixed with the dollar sign

$$\{\text{person.name}\}$$

Note: EL implicit objects are not the same as the implicit objects available to JSP scripting, except for pageContext.

### EL Implicit Object

- pageScope
- requestScope
- sessionScope
- applicationScope
- param
- paramValues
- header
- headerValues
- cookie
- initParam
- pageContext

Of all the implicit objects, only pageContext is not a map. It’s an actual reference to the pageContext object! (And the pageContext is a JavaBean.)
**Using the dot (.) operator to access properties and map values**

The first variable is either an implicit object or an attribute, and the thing to the right of the dot is either a map *value* (if the first variable is a map) or a bean *property* if the first variable is an attribute that's a JavaBean.

1. **If the expression has a variable followed by a dot, the left-hand variable MUST be a Map or a bean.**

   ```
   ${person.name}
   ```

   When the variable is on the left side of the dot, it's either a Map (something with keys) or a bean (something with properties).

   This is true regardless of whether the variable is an implicit object or an attribute.

   The `pageContext` implicit object is a bean—it has getter methods. All other implicit objects are Maps.

2. **The thing to the right of the dot MUST be a Map key or a bean property.**

   ```
   ${person.name}
   ```

   ```
   name = "Evan"
   ```

3. **And the thing on the right must follow normal Java naming rules for identifiers.**

   ```
   ${person.name}
   ```

   * Must start with a letter, _, or $.
   * After the first character, you can include numbers.
   * Can't be a Java keyword.
The [] operator is like the dot only way better

The dot operator works only when the thing on the right is a bean property or map key for the thing on the left. That’s it. But the [] operator is a lot more powerful and flexible...

This:

```
${person."name"}
```

is the same
as this:

```
${person.name}
```

The simple dot operator version works because person is a bean, and name is a property of person.

But what if person is an array?

Or what if person is a List?

Or what if name is something that can’t be expressed with the normal Java naming rules?
but the [ ] is better

The [ ] gives you more options...

When you use the dot operator, the thing on the left can be only a Map or a bean, and the thing on the right must follow Java naming rules for identifiers. But with the [ ], the thing on the left can also be a List or an array (of any type). That also means the thing on the right can be a number, or anything that resolves to a number, or an identifier that doesn’t fit the Java naming rules. For example, you might have a Map key that’s a String with dots in the name (“com.foo.trouble”).

1. If the expression has a variable followed by a bracket [], the left-hand variable can be a Map, a bean, a List, or an array.

\[
\text{musicList["something"]}
\]

2. If the thing inside the brackets is a String literal (i.e., in quotes), it can be a Map key or a bean property, or an index into a List or array.

\[
\text{musicList["something"]}
\]
Using the [] operator with an array

**In a Servlet**

```java
String[] favoriteMusic = {"Zero 7", "Tahiti 80", "BT", "Frou Frou"};
request.setAttribute("musicList", favoriteMusic);
```

**In a JSP**

```jsp
Music is: 

```
First song is: 

Second song is: 

This is a joke, right? Or else there's more than punch in this drink... I could SWEAR that those are quoted around the array index, and that's just not right, dude...
```

Makes sense... calls toString() on the array.

duh..

you are here

371
**accessing lists and arrays**

### A String index is coerced to an int for arrays and Lists

The EL for accessing an array is the same as the EL for accessing a List.

Remember folks, this is NOT Java. In EL, the [ ] operator is NOT the array access operator. No, it’s just called the [ ] operator. (We swear, look it up in the spec—it has no name! Just the symbol [ ]. Like Prince, kind of.) If it DID have a name, it would be the array/List/Map/bean Property access operator.

**In a Servlet**

```java
collections.ArrayList favoriteFood = new java.util.ArrayList();
favoriteFood.add("chai ice cream");
favoriteFood.add("tajitas");
favoriteFood.add("thai pizza");
favoriteFood.add("anything in dark chocolate");
request.setAttribute("favoriteFood", favoriteFood);
```

**In a JSP**

```
Foods are: ${favoriteFood}
```

Obviously ArrayList has a nice overridden toString()

```
Foods are: [chai ice cream, tajitas, thai pizza, anything in dark chocolate]
```

```
First food is ${favoriteFood[0]}
```

First food is chai ice cream

```
Second food is ${favoriteFood["1"]}
```

Second food is fajitas

If the thing to the left of the bracket is an array or a List, and the index is a String literal, the index is coerced to an int.

This would NOT work:

```
${favoriteFood["one"]}
```

Because “one” can’t be turned into an int. You’ll get an error if the index can’t be coerced.

Very, very weird, but OK... if that’s the way it works, I’ll have to get used to it.
Chapter 8. Script-free pages

---

**scriptless JSPs**

Face the facts, dot-boy. I'm way cooler than you. Do you know what it says in the spec about you? It calls you a convenience operator. That's almost too cute.

Oh come on, seriously, does ANYBODY use arrays anymore? Arrays and lists are so... 2003. Linear. Boring.

Right... like Hashtables haven't been around since the stone age.

The fact that you even used the word HashTable shows how up to date YOU are. They're, like, legacy code now. I'm talking about Maps and JavaBeans. That's all anyone uses these days.

Have you actually checked the date on the JavaBeans spec lately? If that spec were milk, it would be some hideous creature from the X-Files by now...

You just don't get it.
[] and the dot

For beans and Maps you can use either operator

For JavaBeans and Maps, you can use either the [] operator or the convenient dot operator. Just think of map keys the same way you think of property names in a bean.

You ask for the key or property name, and you get back the value of the key or property.

In a Servlet

```java
Map musicMap = new HashMap();
musicMap.put("Ambient", "Zero 7");
musicMap.put("Surf", "Tahiti 80");
musicMap.put("DJ", "BT");
musicMap.put("Indie", "Travis");
request.setAttribute("musicMap", musicMap);
```

In a JSP

```
<%=
Map musicMap = new HashMap();
musicMap.put("Ambient", "Zero 7");
musicMap.put("Surf", "Tahiti 80");
musicMap.put("DJ", "BT");
musicMap.put("Indie", "Travis");
request.setAttribute("musicMap", musicMap);
%>
```

Ambient is: ${musicMap.Ambient}

Ambient is: Zero 7

Both expressions use Ambient as the key into a Map (since musicMap is a Map!).

Ambient is: ${musicMap["Ambient"]}

Ambient is: Zero 7

Both expressions use Ambient as the key into a Map (since musicMap is a Map!).
If it’s NOT a String literal, it’s evaluated

If there are no quotes inside the brackets, the Container evaluates what’s inside the brackets by searching for an attribute bound under that name, and substitutes the value of the attribute. (If there is an implicit object with the same name, the implicit object will always be used.)

```
Music is: ${musicMap[Ambient]}
```

*Find an attribute named “Ambient”.*

*Use the VALUE of that attribute as the key into the Map, or return null.*

In a servlet

```java
java.util.Map musicMap = new java.util.HashMap();
musicMap.put("Ambient", "Zero 7");
musicMap.put("Surf", "Tahiti 80");
musicMap.put("DJ", "BT");
musicMap.put("Indie", "Frou Frou");
request.setAttribute("musicMap", musicMap);
request.setAttribute("Genre", "Ambient");
```

This DOES work in a JSP

```text
Music is ${musicMap[Genre]}
```

because there IS a request attribute named “Genre” with a value of “Ambient”, and “Ambient” is a key into musicMap.

This does NOT work in a JSP (given the servlet code)

```text
Music is ${musicMap["Genre"]}
```

because there IS no key in musicMap named “Genre”.

With the quotes around it, the Container didn’t try to evaluate it and just assumed it was a literal key name.

Without quotes around Ambient, this does NOT work! Since there’s no bound attribute named “Ambient”, the result comes back null.
nested expressions

You can use nested expressions inside the brackets

It’s expressions all the way down in EL. You nest expressions to any arbitrary level. In other words, you can put a complex expression inside a complex expression inside a... (it keeps going). And the expressions are evaluated from the inner most brackets out.

This part will seem completely intuitive to you, because it’s no different than nesting Java code within parens. The tricky part is to watch out for quotes vs. no quotes.

In a servlet

```java
java.util.Map musicMap = new java.util.HashMap();
musicMap.put("Ambient", "Zero 7");
musicMap.put("Surf", "Tahiti 80");
musicMap.put("DJ", "87");
musicMap.put("Indie", "Frou Frou");
request.setAttribute("musicMap", musicMap);

String[] musicTypes = {"Ambient", "Surf", "DJ", "Indie");
request.setAttribute("MusicType", musicTypes);
```

This DOES work in a JSP

```html
Music is ${musicMap[MusicType[0]]}
```

This becomes

```html
Music is Zero 7
```

```html
Music is ${musicMap["Ambient"]}
```

This becomes

```html
Music is Zero 7
```
**You can’t do ${{foo .1}}**

With beans and Maps, you can use the dot operator, but only if the thing you type after the dot is a legal Java identifier.

This

```java
${musicMap.Ambient}  // works
```

Is the same as this

```java
${musicMap['Ambient']}  // works
```

But this

```java
${musicList['1']};
```

CANNOT be turned into this

```java
${musicList.1};  // NO! NO! NO!
```

---

**Sharpen your pencil**

What prints?

Given the servlet code below, figure out what would print (or if there’d be an error, just write, you know, “error”). Answers are at the bottom of the next page.

```java
java.util.ArrayList nums = new java.util.ArrayList();
nums.add("1");
nums.add("2");
nums.add("3");
request.setAttribute("numbers", nums);
String[] favoriteMusic = {"Zero 7", "Tahiti 80", "BT", "Frou Frou");
request.setAttribute("musicList", favoriteMusic);
```

1. `$(musicList[numbers[0]])`
2. `$(musicList[numbers[0]+1])`  
   *(We’ll talk more about EL operators in a few pages.)*
3. `$(musicList[numbers["2"])`
4. `$(musicList[numbers[numbers[1]])`

---

*(We’ll talk more about EL operators in a few pages.)*
**Big exercise on EL**

**Code Magnets**

Don’t be surprised if you find something like this on the exam (except in the real exam it’ll look uglier).

Study the three classes on the page, and the servlet code on the opposite page, then construct the code magnets to make the EL that’ll produce the response shown in the browser. (Turn the page for the answers, but not until you DO THIS, especially if you’re going to take the exam.)

---

```java
package foo;
public class Toy {
    private String name;
    public void setName(String name) {
        this.name = name;
    }
    public String getName() {
        return name;
    }
}
```

```java
package foo;
public class Dog {
    private String name;
    private Toy[] toys;
    public void setName(String name) {
        this.name = name;
    }
    public String getName() {
        return name;
    }
    public void setToys(Toy[] toys) {
        this.toys = toys;
    }
    public Toy[] getToys() {
        return toys;
    }
}
```

```java
package foo;
public class Person {
    private Dog dog;
    private String name;
    public void setDog(Dog dog) {
        this.dog = dog;
    }
    public Dog getDog() {
        return dog;
    }
    public void setName(String name) {
        this.name = name;
    }
    public String getName() {
        return name;
    }
}
```

---

Answers to Sharpen on previous page: 1) Tahiti 80 2) BT 3) Frou Frou 4) Frou Frou

---

Chapter 8. Script-free pages
Chapter 8. Script-free pages

Servlet code

```java
foo.Person p = new foo.Person();
p.setName("Leelu");
foo.Dog d = new foo.Dog();
d.setName("Clyde");
foo.Toy tl = new foo.Toy();
t1.getName("stick");
foo.Toy t2 = new foo.Toy();
t2.getName("neighbor's cat");
foo.Toy t3 = new foo.Toy();
t3.getName("Barbie doll head");
d.setToys(new foo.Toy[]{t1, t2, t3});
p.setDog(d);
request.setAttribute("person", p);
```

Compose the EL for this output:

Leelu's dog Clyde's toys are: stick, neighbor's cat, and a Barbie doll head

---

**scriptless JSPs**
exercise answers

Code Magnets Answers

This is not the ONLY way to produce the output, but it's the only way using this set of magnets. Bonus exercise: write the EL expressions a little differently (forget the magnets), but print the same result.

Servlet code

```java
foo.Person p = new foo.Employee();
p.setName("LeeLu");
foo.Dog d = new foo.Dog();
d.setName("Clyde");
foo.Toy t1 = new foo.Toy();
t1.setName("stick");
foo.Toy t2 = new foo.Toy();
t2.setName("neighbor\'s cat");
foo.Toy t3 = new foo.Toy();
t3.setName("Barbie\' doll head");
d.setToys(new foo.Toy[] { t1, t2, t3 });
p.setDog(d);
request.setAttribute("person", p);
```

Compose the EL for this output:

```
LeeLu\'s dog Clyde\'s toys are: 

stick, neighbor\'s cat, and a 

Barbie\' doll head
```

```el
$(person.person).dog$(person.person).dog.name

$(person.person).dog.toys[0].name, $(person.person).dog.toys[1].name, and $(person.person).dog.toys[2].name
```

380 chapter 8
Remember that my HTML form action goes straight to the JSP... is there a way I can use the request parameters just using EL?

The EL implicit objects

Remember, EL has some implicit objects. But these are not the same as the JSP implicit objects (except for one, `pageContext`). Here’s a quick list; we’ll look at some of them in more detail on the next few pages. You’ll notice that all but one (pageContext again), are simple Maps—name/value pairs.

- `pageScope`
- `requestScope`
- `sessionScope`
- `applicationScope`
- `param`
- `paramValues`
- `header`
- `headerValues`
- `cookie`
- `initWith`
- `pageContext`

Remember, the only thing that is NOT a Map is the pageContext object, which you can think of as a bean. Look in the API for the PageContext getter methods.
param and paramValues

Request parameters in EL

Piece of cake. The param implicit object is fine when you know you have only one parameter for that particular parameter name. Use paramValues when you might have more than one parameter value for a given parameter name.

In the HTML form

```html
<form action="TestBean.jsp">
  Name: <input type="text" name="name">
  ID#: <input type="text" name="empID">
  First food: <input type="text" name="food">
  Second food: <input type="text" name="food">
  <input type="submit">
</form>
```

In the JSP

Request param name is: ${param.name} <br>
Request param empID is: ${param.empID} <br>
Request param food is: ${param.food} <br>
First food request param: ${paramValues.food[0]} <br>
Second food request param: ${paramValues.food[1]} <br>
Request param name: ${paramValues.name[0]}

In the client's browser (client fills in the form and hits the submit button)

The response

```
Request param name is: Fluffy
Request param empID is: 423
Request param food is: Sushi
First food request param: Sushi
Second food request param: Macaroni & Cheese
Request param name: Fluffy
```
What if you want more information from the request?

What if you want, say, the server host information that comes with the "host" header in the request? If you look in the HttpServletRequest API, you can see a getHeader(String) method. We know that if we pass "host" to the getHeader() method, we'll get back something like: "localhost:8080" (because that's where the web server is).

Getting the "host" header

We know we can do it with scripting

```java
Host is: <% request.getHeader("host") %>
```

But with EL, we've got the header implicit object

```java
Host is: ${header["host"]}
Host is: ${header.host}
```

Getting the HTTP request method

Uh-oh. This is a little trickier... there's a method in the HttpServletRequest API for getMethod(), that returns GET, POST, etc. But how do I get it using EL?

We know we can do it with scripting

```java
Method is: <% request.getMethod() %>
```

But with EL, this will NOT work

```java
Method is: ${request.method}
```

And this will NOT work

```java
Method is: ${requestScope.method}
```

Can you figure out how to do it?

Hint: look at the other implicit objects.

```java
you are here
```
scope maps are NOT the real object

The requestScope is NOT the request object

The implicit requestScope is just a Map of the request scope attributes, not the request object itself! What you want (the HTTP method) is a property of the request object, not an attribute at request scope. In other words, you want something that comes from calling a getter method on the request object (if we treat the request object like a bean).

But there is no request implicit object, only requestScope! What to do? You need something else...

Use requestScope to get request ATTRIBUTES, not request PROPERTIES. For request properties, you need to go through pageContext.

Use pageContext to get to everything else...

Method is: $(pageContext.request.method)

pageContext has a request property
request has a method property

Don't confuse the Map scope objects with the objects to which the attributes are bound.

It's so easy to think that, say, applicationScope is a reference to ServletContext, since that's where application-scoped attributes are bound. But just as with requestScope and the request object, the scope Map for application-scoped attributes is just that—a Map of attributes, and nothing more. You can't treat it like a ServletContext, so don't expect to get ServletContext properties back from the applicationScope implicit object!
Scope implicit objects can save you

If all you need is to print the name of a person, and you really don’t care what scope the person is in (or, you do care, but you know there’s only one person out of all four scopes), you just use:

```
${person.name}
```

Or, if you’re worried about a potential naming conflict, you can be explicit about which person you want:

```
${requestScope.person.name}
```

But is there another reason you might have to preface the attribute with the implicit scope object? Other than to control...scoping?

Think about this scenario: if you have a name that’s not in quotes in brackets {}, that means it MUST adhere to Java naming rules, right? Here, we’re OK, because person is a perfectly legal Java variable name. But that’s because somewhere, someone said,

request.setAttribute("person", p);

But an attribute name is a String!

Strings don’t follow Java variable name rules!

That means someone could say:

```
request.setAttribute("foo.person", p);
```

And then you’d be in trouble, because THIS won’t work:

```
${foo.person.name}
```

But you’ll be so thankful for scope objects, because using a scope object lets you switch to the [] operator, that can take String names that don’t conform to Java naming rules.

```
${requestScope["foo.person"].name}
```
two more implicit objects

Getting Cookies and init params

We’ve looked at all the implicit objects except cookies and init params, so here we are. And yes, any of the implicit objects can show up on the exam.

Printing the value of the “userName” Cookie

We know we can do it with scripting

```java
<% Cookie[] cookies = request.getCookies();
for (int i = 0; i < cookies.length; i++) {
    if (cookies[i].getName().equals("userName") == true) {
        out.println(cookies[i].getValue());
    }
} %>
```

But with EL, we’ve got the Cookie implicit object

```java
${cookie.userName}val
```

Printing the value of a context init parameter

We have to configure the parameter in the DD

```xml
<context-param>
    <param-name>mainEmail</param-name>
    <param-value>likewecare@wickedlysmart.com</param-value>
</context-param>
```

We know we can do it with scripting

```java
email is: <%= application.getInitParameter("mainEmail") %>
```

And with EL, it’s even easier

```java
email is: ${initParam.mainEmail}
```

Here’s what’s confusing: servlet init params are configured using `<init-param>` while context params use `<context-param>`, but the EL implicit “initParam” is for context params! Had they consulted us, we would have suggested the spec designers might consider naming this variable, oh, “contextParam”… but once again, they forgot to ask us.
She doesn’t know about EL functions

When you need a little extra help from, say, a Java method, but you don’t want scripting, you can use an EL function. It’s an easy way to write a simple EL expression that calls a static method in a plain old Java class that you write. Whatever the method returns is used in the expression. It does take a tiny bit more work to configure things, but functions give you a lot more functionality.
Imagine you want your JSP to roll dice

You’ve decided it would be awesome to have a web-based dice-rolling service. That way, instead of hunting around behind desks and in the sofa cushions for real dice, a user could just go to your web page, click on the virtual dice, and voila! They roll! (Of course, you have no idea that a Google search will probably bring up, oh, about 4,420 sites that do this.)

1. **Write a Java class with a public static method.**
   
   This is just a plain old Java class. The method MUST be public and static, and it can have arguments. It should (but isn’t required to) have a non-void return type. After all, the whole point is to call this from a JSP and get something back that you can use as part of the expression or to print out.
   
   Put the class file in the WEB-INF/classes directory structure (matching the appropriate package directory structure, just like you would with any other class).

2. **Write a Tag Library Descriptor (TLD) file.**
   
   For an EL function, the TLD provides a mapping between the Java class that defines the function and the JSP that calls the function. That way, the function name and the actual method name can be different. You might be stuck with a class with a really stupid method name, for example, and maybe you want to provide a more obvious or intuitive name to page designers using EL. No problem—the TLD says: “This is the Java class, this is the method signature for the function (including return type) and this is the name we’ll use in EL expressions”. In other words, the name used in EL doesn’t have to be the same as the actual method name, and the TLD is where you map that.
   
   Put the TLD file inside the WEB-INF directory. Name it with a .tld extension. (There are other places the TLD can go; we’ll talk about that in the next two chapters.)

3. **Put a taglib directive in your JSP.**
   
   The taglib directive tells the Container, “I’m going to use this TLD, and in the JSP, when I want to use a function from this TLD, I’m going to prefix it with this name...” In other words, it lets you define the namespace. You can use functions from more than one TLD, and even if the functions have the same name, that’s OK. The taglib directive is kind of like giving all your functions fully-qualified names. You invoke the function by giving both the function name AND the TLD prefix. The prefix can be anything you like.

4. **Use EL to invoke the function.**
   
   This is the easy part. You just call the function from an expression using ${prefix.name}().
The function class, the TLD, and the JSP

The function method MUST be public AND stable.

The class with the function

```java
package foo;
public class DiceRoller {
    public static int rollDie() {
        return (int) (Math.random() * 6) + 1;
    }
}
```

The Tag Library Descriptor (TLD) file

```xml
<?xml version="1.0" encoding="ISO-8859-1" ?>
<taglib xmlns="http://java.sun.com/xml/ns/j2ee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee/web-jstl/1.2.xsd" version="2.0">
    <tlib-version>1.2</tlib-version>
    <function>
        <name>rollIt</name>
        <function-class>foo.DiceRoller</function-class>
        <function-signature>
            int rollDie()
        </function-signature>
    </function>
</taglib>
```

The JSP

```jsp
<%@ taglib prefix="mine" uri="DiceFunctions" %>
<html><body>

\$\{mine:rollIt()\}

</body></html>
```

The prefix "mine" is just the nickname we'll use inside THIS page, so that we can tell one TLD from another (in case you DO have more than one).

Page 389
**Deploying an app with static functions**

The only thing that's new here is the "myFunctions.tld" file. It has to be somewhere within WEB-INF or one of its subdirectories (unless it's deployed in a JAR file, but we'll talk about that later in the book). Here, because this app is so simple, we have both the DD (web.xml) and the TLD (myFunctions.tld) at the top level of WEB-INF, but you could organize them into subdirectories.

The key point is that the class with the static function MUST be available to the app, so... for now, you know that putting it inside WEB-INF/classes will work. And remember that in the `taglib` directive in the JSP, we specified a URI that matches the URI declared in the TLD. For now, think of the URI as simply whatever you decided to name the TLD. It's just a name. In the next chapter on using custom tags, we'll go into all the details about TLDs and URIs.

```xml
<taglib prefix="mine" uri="DiceFunctions"/>
```

The class with the function (the public static method) must be available to the web app just like servlet, bean, and listener classes. That means somewhere in WEB-INF/classes...

Put the TLD file somewhere under WEB-INF, and make sure the `taglib` directive in the JSP includes a `uri` attribute that matches the `<uri>` element in the TLD.
Q: A regular scriptlet expression MUST return something. If you say `<%= foo, getFoo() %>, getFoo()` must NOT have a void return type. (At least that’s what you said earlier.) So I’m thinking it’s the same with EL functions?

A: No! It’s NOT the same with EL functions, although just about everybody finds that surprising. Think about this—if you’re calling an EL function that doesn’t return anything, then you’re calling it just for its side effects! Given that part of the goal for EL is to reduce the amount of logic in a JSP (a JSP supposed to be the VIEW), invoking an EL function just for its side effects doesn’t sound like a good idea.

Q: How did the Container find the TLD? The URI doesn’t match the path or file name of the TLD. Was this a miracle?

A: Just the question we were hoping someone would ask. Yes, you’re right—we never did tell the Container exactly where to find the real TLD file. When the app is deployed, the Container searches through WEB-INF and its subdirectories (or in JAR files within WEB-INF/lib) looking for .did files. When it finds one, it reads the URI and creates a map that says, “The TLD with this URI is actually this file at this location...” There’s a little more to the story that we’ll cover in the next chapter.

Q: Can an EL function have arguments?

A: Definitely. Just remember in the TLD to specify the fully-qualified class name (unless it’s a primitive) for each argument. A function that takes a Map would be:

```
<function-signature>
int rollDice(java.util.Map)
</function-signature>
```
EL operators

And a few other EL operators...

You probably won’t (and shouldn’t) do calculations and logic from EL. Remember, a JSP is the View, and the View’s job is to render the response, not to make Big Important Decisions or do Big Processing. If you need real functionality, that’s normally the job of the Controller and Model. For lesser functionality, you’ve got custom tags (including the JSTL tags) and EL functions.

But... for little things, sometimes a little arithmetic or a simple boolean test might come in handy. So, with that perspective, here’s a look at the most useful EL arithmetic, relational, and logical operators.

Arithmetic (5)

Addition: +
Subtraction: -
Multiplication: *
Division: / and div
Remainder: % and mod

By the way... you CAN divide by zero in EL—you get INFINITY, not an error. But you CANNOT use the Remainder operator against a zero—you’ll get an exception.

Logical (3)

AND: && and and
OR: || and or
NOT: ! and not

Relational (6)

Equals: == and eq
Not equals: != and ne
Less than: < and lt
Greater than: > and gt
Less than or equal to: <= and le
Greater than or equal to: >= and ge

Watch it!

Don’t use EL reserved words as identifiers!

You can already see 11 of them on this page—the alternate “words” for the relational, logical and some arithmetic operators. But there are a few more:

true a boolean literal
false the OTHER boolean literal
null It means... null
instanceof (this is reserved for “the future”)
empty an operator to see if something is null or empty (e.g. $[empty]) returns true if A is null or empty (you’ll see this in action a little later in the chapter)
Look at the servlet code, then figure out what prints next to each EL expression.
You’ll have to guess in a few places, since we haven’t covered every possible rule.
This exercise will help you figure out how EL behaves. Hint: EL is flexible and forgiving.
Another hint: the actual nine answers are printed at the bottom of this page upside down, but they are NOT in any order. But if you really need help, at least you’ll have the nine answers, and you can use elimination to figure out where they all go.

**Given this servlet code:**

```java
String num = "2";
request.setAttribute("num", num);
Integer i = new Integer(3);
request.setAttribute("integer", i);
java.util.ArrayList list = new java.util.ArrayList();
list.add("true");
list.add("false");
list.add("2");
list.add("10");
request.setAttribute("list", list);
```

**What prints for each of these?**

Assume that the Dog bean class and rollIt() function are both available.

- $(num > 3)
- $(integer le 12)
- ${requestScope[integer] ne 4 and 6 le num || false}
- ${list[0] || list["1"] and true}
- $(num > integer)
- $(num == integer-1)

```xml
<jsp:useBean class="foo.Dog" id="myDog" value="/list[1]" />
```

- $(myDog.name and true)
- $(42 div 0)
- $(miner:rollIt() le 0)
**EL operator answers**

Given this servlet code:

```java
String num = "2";
request.setAttribute("num", num);
Integer i = new Integer(3);
request.setAttribute("integer", i);
java.util.ArrayList list = new java.util.ArrayList();
list.add("true");
list.add("false");
list.add("2");
list.add("10");
request.setAttribute("list", list);
```

What prints for each of these?

- `false`  
  `$$\{\text{num > }3\}$$`  
  The "num" attribute was found, and its value "2" coerced to an int.

- `true`  
  `$$\{\text{integer le }12\}$$`  
  Even better! The integer value was converted to its primitive value, and then compared.

- `false`  
  `$$\{\text{requestScope[\text{integer}] ne }4 \text{ and } 6 \text{ le num || false}\}$$`  
  See if you can figure out the precedence rules for when you don't use parens. It's very intuitive (left to right), and you should have NO problems with precedence on the exam.

- `true`  
  `$$\{\text{list[0] || list["2"] and true}\}$$`  
  There is NO `= in EL`

- `false`  
  `$$\{\text{num > integer}\}$$`  
  Watch out for using `==` instead of `==`. There is NO `= in EL`

- `true`  
  `$$\{\text{num == integer-1}\}$$`  
  `<$jsp:useBean class="foo.Dog" id="myDog"$>  
  <$jsp:setProperty name="myDog" property="name" value="\$\{list[1]\}" />$>`

- `false`  
  `$$\{\text{myDog.name and true}\}$$`

- `Infinity`  
  `$$\{\text{42 div 0}\}$$`

- `false`  
  `$$\{\text{mine.rollIt() le 0}\}$$`

If you remember the `rollIt()` code, it always returns a number greater than zero.
EL handles null values gracefully

A key design decision the developers of EL came up with is to handle null values without throwing exceptions. Why? Because they figured “it’s better to show a partial, incomplete page than to show the user an error page.”

Assume that there is not an attribute named “foo”, but there IS an attribute named “bar”, but that “bar” does not have a property or key named “foo”.

<table>
<thead>
<tr>
<th>EL</th>
<th>What prints</th>
</tr>
</thead>
<tbody>
<tr>
<td>$[foo]</td>
<td>Nothing prints out for these expressions. If you say “The value is [[foo]].” You’ll just see “The value is”</td>
</tr>
<tr>
<td>$[foo[bar]]</td>
<td></td>
</tr>
<tr>
<td>$[bar[foo]]</td>
<td></td>
</tr>
<tr>
<td>$[foo.bar]</td>
<td></td>
</tr>
<tr>
<td>$[7 + foo]</td>
<td>7</td>
</tr>
<tr>
<td>$[7 / foo]</td>
<td>Infinity</td>
</tr>
<tr>
<td>$[7 - foo]</td>
<td>7</td>
</tr>
<tr>
<td>$[7 % foo]</td>
<td>Exception is thrown</td>
</tr>
<tr>
<td>$[7 &lt; foo]</td>
<td>false</td>
</tr>
<tr>
<td>$[7 == foo]</td>
<td>false</td>
</tr>
<tr>
<td>$[foo == foo]</td>
<td>true</td>
</tr>
<tr>
<td>$[7 != foo]</td>
<td>true</td>
</tr>
<tr>
<td>$[true and foo]</td>
<td>false</td>
</tr>
<tr>
<td>$[true or foo]</td>
<td>true</td>
</tr>
<tr>
<td>$[not foo]</td>
<td>true</td>
</tr>
</tbody>
</table>

EL is null-friendly. It handles unknown or null values so that the page still displays, even if it can’t find an attribute/property/key with the name in the expression.

In arithmetic, EL treats the null value as “zero”.

In logical expressions, EL treats the null value as “false”.
EL review

**JSP Expression Language (EL) review**

**BULLET POINTS**

- EL expressions are always within curly braces, and prefixed with a dollar($) sign ${expression}.
- The first named variable in the expression is either an implicit object or an attribute in one of the four scopes (page, request, session, or application).
- The dot operator lets you access values by using a Map key or a bean property name, for example $[foo.bar] gives you the value of bar, where bar is the name of Map key into the Map foo, or bar is the property of bean foo. Whatever comes to the right of the dot operator must follow normal Java naming rules for identifiers! (In other words, must start with a letter, underscore, or dollar sign, can include numbers after the first character, but nothing else, etc.)
- You can NEVER put anything to the right of the dot that wouldn’t be legal as a Java identifier. For example, you can’t say ${foo!}.
- The [] operator is more powerful than the dot, because it lets you access arrays and Lists, and you can put other expressions including named variables within the brackets, and you can nest them to any level you can stand.
- For example, if musicList is an ArrayList, you can access the first value in the list by saying $[musicList[0]] or $[musicList[0]]. EL doesn’t care if you put quotes around the list index.
- If what’s inside the brackets is not in quotes, the Container evaluates it. if it is in quotes, and it’s not an index into an array or List, the Container sees it as the literal name of a property or key.
- All but one of the EL implicit objects are Maps. From the Map implicit objects you can get attributes from any of the four scopes, request parameter values, header values, cookie values, and context init parameters. The non-map implicit object is pageContext, which is a reference to... the PageContext object.
- Don’t confuse the implicit EL scope objects (Maps of the attributes) with the objects to which the attributes are bound. In other words, don’t confuse the requestScope implicit object with the actual JSP implicit request object. The only way to access the request object is by going through the pageContext implicit object. (Although some of what you might want from the request is already available through other EL implicit objects, including param/paramValues, header/headerValues, and cookie.)
- EL functions allow you to call a public static method in a plain old Java class. The function name does not have to match the actual method name! For example, ${foo(rollIt)} does not mean that there must be a method named rollIt() in a class that has a function.
- The function name (e.g. rollIt()) is mapped to a real static method using a TLD (Tag Library Descriptor) file. Declare a function using the <function> element, including the <name> of the function (rollIt()), the fully-qualified <func-class>, and the <function-signature> which includes the return type as well as the method name and argument list.
- To use a function in a JSP, you must declare the namespace using a taglib directive. Put a prefix attribute in the taglib directive to tell the Container the TLD in which the function you’re calling can be found. Example:

```jsp
<%@ taglib prefix="mine" uri="/WEB-INF/foo.tld"%>
```
Hey, have you guys noticed that they haven't even mentioned, like, the ONE thing that's most important to a web site designer?

Yeah, I haven't heard ONE thing about using layout templates. The last thing I want to do is put the same navigation bar code into all 23 of my JSPs... what if it changes?

Hmmm... I always thought the important thing was to make sure you don't end up on webpagesthatstuck.com.
layout templates

OF COURSE we'll talk about layout templates. If ANYONE knows about reusable components it's a Java programmer.

Reusable template pieces

You have headers on every page on your web site. They’re always the same. You have the same footer on every page as well. How stupid would it be to code in the same header and footer tags into every JSP in your web app?

If you’re thinking like a Java programmer (which of course you are), you know that doing that is about as un-OO as it gets.

The thought of all that duplicate code probably makes you feel a little sick. What happens when the site designer makes, oh, a tiny little change to the header or footer?

You have to propagate the change everywhere. Relax. There’s a mechanism for handling this in a JSP—it’s called include: You write your JSP in the usual way, except that instead of putting the reusable stuff explicitly into the JSP you’re authoring, you instead tell the Container to include the other file into the existing page, at the location you select. It’s kind of like saying:

```html
<html>
<body>
   <!-- insert the header file here -->
Welcome to our site...
   blah blah blah more stuff here...
   <!-- insert the footer file here -->
</body></html>
```

In this section we’ll look at two different include mechanisms: the include directive and the `jsp:include` standard action.
The include directive

The include directive tells the Container one thing: copy everything in the included file and paste it into this file, right here...

Standard header file (“Header.jsp”)

```html
<html><body>
  <img src="images/Web-Services.jpg"/>
  We know how to make SOAP suck less. 
</body></html>
```

A JSP from the web app (“Contact.jsp”)

```html
<html><body>
  <% include file="Header.jsp"%>
  We can help.
  Contact us at: ${initParam.mainEmail}
</body></html>
```
<jsp:include> standard action

The <jsp:include> standard action

The <jsp:include> standard action appears to do the same thing as the include standard action.

Standard header file (“Header.jsp”)

```html
<html><body>
<% include page="Header.jsp" %>
<br>
<em>We know how to make SOAP suck less.</em>
</body></html>
```

A JSP from the web app (“Contact.jsp”)

```html
<html><body>
<% include page="Header.jsp" %>
<br>
<em>We can help.</em><br>
Contact us at: <%=initParam.mainEmail%>
</body></html>
```

This says “Insert the response of Header.jsp file into this point in THIS page, then keep going with the rest of this JSP.”

We know how to make SOAP suck less.

We can help.

Contact us at: likewecare@wickedlysmart.com

400  chapter 8
They’re NOT the same underneath...

The `<jsp:include />` standard action and the include directive look the same, and often give the same result, but take a look at the generated servlets. We took this code directly out of the `<jspService()>` method from Tomcat’s generated servlet code...

Generated servlet code for the header file

```java
out.write("<html<body>
<em><img src="images/Web-Services.jpg" />
<br><strong>We know how to make SOAP suck less.</strong></em>
</body>");
```

Simple... it just does the output.

Generated servlet for the JSP using the include directive

```java
out.write("<html<body>
<em><img src="images/Web-Services.jpg" />
<br><strong>We know how to make SOAP suck less.</strong></em>
</body>");
```

This part in bold is EXACTLY the same as the Header.jsp page generates.

```java
out.write("<br><em>We can help.</em>
<br><strong>Contact us at: "});
proprietaryEvaluate("[initParam.mainEmail]", java.lang.String.class,
(PageContext)_jspx_page_context, null, false));
```

The include directive just takes the contents of the page BEFORE it does the translation!

Generated servlet for the JSP using the `<jsp:include />` standard action

```java
org.apache.jasper.runtime.JspRuntimeLibrary.include(request, response,
"Header.jsp", out, false);
```

This is different! The original Header.jsp file is NOT inside the generated servlet, instead, it’s some kind of runtime call...

```java
out.write("<br><em>We can help.</em>
<br><strong>Contact us at: "});
proprietaryEvaluate("[initParam.mainEmail]", java.lang.String.class,
(PageContext)_jspx_page_context, null, false));
```

you are here ➔ 401
include directive vs. standard action

The include directive happens at translation time

The include directive happens at runtime

With the include directive, there is NO difference between you opening your JSP page and pasting in the contents of "Header.jsp". In other words, it really is just as though you duplicated the code from the header file into your other JSP. Except the Container does it at translation time for you, so that you don’t have to duplicate the code everywhere. You can write all your pages with an include directive, and the Container will go through the trouble of copying the header code into each JSP before translating and compiling the generated servlet.

But <jsp:include> is a completely different story. Rather than copying in the source code from "Header.jsp", the include standard action inserts the \( \text{response} \) of "Header.jsp", at runtime. The key to <jsp:include> is that the Container is creating a RequestDispatcher from the page attribute and applying the include() method. The dispatched/included JSP executes against the same request and response objects, within the same thread.

The include directive inserts the SOURCE of "Header.jsp", at translation time.
But the \(<\text{jsp:include }\rangle\text{ standard action inserts the RESPONSE of “Header.jsp”, at runtime.}\)

Q: So why wouldn’t you always use \(<\text{jsp:include}>\)? That way you can guarantee you’ll always have the latest content.

A: Think about it. There’s an extra performance hit with every \(<\text{jsp:include}>\). With the directive, on the other hand, the hit happens only once—when the including page is translated. So if you’re pretty sure that once you go to production the included file won’t change, the directive might be the way to go. Of course there’s still the tradeoff that the generated servlet class is a little larger when you use the directive.

Q: I tried this with Tomcat— I made a static HTML file, and included it with the directive. Then I changed the HTML file, without redeploying or anything, and the output from the JSP reflected the difference! So if that’s the case, then why ever use \(<\text{jsp:include}>\)?

A: Ahhh... you have a friendly Container (like Tomcat 5). Yes, most of the newer Containers have a way of detecting when the included files have changed, and they do retranslate the included file and everything’s great. The problem is that this is NOT GUARANTEED BY THE SPEC! So if you write your code to depend on it, your app won’t necessarily be portable to other Containers.
The **include** directive at first request

With the **include** directive, the Container has a lot of work to do, but **only** on the first request. From the second request on, there’s no extra runtime overhead.

1. **request Contact.jsp**
   - request file
   - read file
   - Contact.jsp
   - Header.jsp
   - The client makes a request for Contact.jsp, which has not been translated. The Container reads the Contact.jsp page to start the translation process.

2. **combine**
   - translate into
   - Contact.jsp.java
   - The container sees the include directive, and combines the source code of Header.jsp and Contact.jsp, and creates/translates that into a Java source file for the generated servlet.

3. **Compile into**
   - Contact.jsp.java
   - Contact.jsp_class
   - The Container compiles the translated source file into a servlet class. It’s just like any other servlet at this point, and the previous step never has to happen again, unless Contact.jsp changes (or, if your Container is smart and can tell that the included Header.jsp has changed).

4. **Call class**
   - (A) load class
   - (B) initialize servlet
   - (C) service
   - Contact
   - Contact.jsp_class
   - Contact.jsp
   - Header.jsp
   - To complete the request, the Container loads the newly-compiled class, initializes a servlet (instantiates the servlet then calls init) on the new object), allocates a thread for the request, and calls the _jspService() method. From the second request on, the Container does only step (C): allocates a thread and calls the _jspService() method.
The `<jsp:include>` standard action at first request

With the include standard action, there’s less work at translation time, and more work with each request, especially if the included file is a JSP.

1. The client makes a request for Contact.jsp, which has not been translated. The Container reads the Contact.jsp page to start the translation process.

2. The container sees the include standard action, and uses that to insert a method call in the generated servlet code that—at runtime—will dynamically combine the response from Header.jsp into the response from Contact.jsp. The Container generates servlets for both JSP files. (This is not dictated by the spec, so we’re showing only an example of how it could work.)

3. The Container compiles the translated source file into a servlet class. It’s just like any other servlet at this point. The generated servlet class file is loaded into the Container’s JVM and is initialized. Next, the Container allocates a thread for the request and calls the JSP’s `_jspService()` method.

4. The Contact servlet hits the method that does the dynamic include, and something vendor-specific happens! All we care about is that the response generated by the Header servlet is combined with the response from the Contact servlet (at the appropriate place). (NOT SHOWN: at some point the Header.jsp is translated and compiled, then the generated servlet class is loaded and initialized.)
**Q:** Can the included JSP have its own dynamic content? In your examples, the Header.jsp might as well have been a static Header.html page.

**A:** It’s a JSP, so yes it can be dynamic (but you’re right—it in our example we could have made the header a static HTML page and it would have worked in exactly the same way). There are a few limitations, though: an included page CANNOT change the response status code or set headers (which means it can’t call, say, addCookies()). You won’t get an error if the included JSP tries to do things it can’t—you just won’t get what you asked for.

**Q:** But if the included thing is dynamic, and you’re using the static include directive, does that mean that the dynamic stuff is evaluated only once?

**A:** Let’s say you include a JSP that has an EL expression that calls the rollit function that generates a random number. Remember, with the include directive, that EL expression is simply copied into the inclusion JSP. So each time that page is accessed, the EL expression runs and a new random number is generated. But this is not the include directive, the source of the included thing becomes PART of the page with the include directive.

And it’s the ONLY directive whose position in the JSP actually matters. With a page directive, for example, you can put it anywhere in the page, although by convention most people put page directives at the top.

But the include directive tells the Container exactly WHERE to insert the source from the included file! For example, if you’re including both a header and a footer, it might look something like this: 

```jsp
<%@ include file="Header.jsp" %>

<%@ include file="Footer.html" %>
```

This has to be at the bottom of your JSP (before the closing tag), if that’s where you want the stuff from Footer.html to appear. Remember, everything from the JSP plus the two included files is combined into one big page, and THE ORDER MATTERS!

And, yes, the `<jsp:include>` is of course ALSO position-sensitive, but that’s more obvious than with the page directive.
Uh-oh. She's right...

Think about what we did. We made a page for the header, "Header.jsp". It was a nice JSP all on its own, complete with its opening and closing HTML and BODY tags. Then we made the "Contact.jsp" and it, too, had nice opening and closing tags. Well, didn’t we say that everything in the included file is pasted (virtually) into the page with the include? That means everything.

The code below, from the generated servlet, will NOT work in all browsers. It worked in ours because we got lucky.

```java
out.write("<html><body>\r\n";
out.write("<html>\r<body>
<img src="images/Web-Services.jpg" />
<em><strong>We know how to make SOAP suck less.</strong></em> \r
</body></html>\r\n");
out.write("\r\r\r<em>We can help.</em> \r
Contact us at: ");
out.write((java.lang.String) org.apache.jasper.runtime.
PageContextImpl[proprietaryEvaluate("$\{initParam.
mainEmail\}\", java.lang.String.class,
(PageContext) _jspx_page_context, null, false));
out.write("<body></html>");
```

**Do NOT put opening and closing HTML and BODY tags within your reusable pieces!**

Design and write your layout template chunks (like headers, nav bars, etc.) assuming they will be included in some OTHER page.
The way we SHOULD have done it

Here we took the opening and closing tags out of the included files. This does mean that the included files can no longer generate valid HTML pages on their own; they now depend on being included in something bigger. Something with <html><body> and </body></html> tags. But that’s the point—you’re designing these reusable chunks so that you can compose complete layouts from smaller pieces, without duplicating the code by hand. These reusable chunks aren’t meant to live on their own.

1. The Header file ("Header.jsp")

```html
<img src="images/Web-Services.jpg" />
<br />
<br />
<em><strong>We know how to make SOAP suck less.</strong></em>
<br />
<br />
```.

2. Contact.jsp

```html
<html>
<body>

<%@ include file="Header.jsp" %>
<br />
<br />
<em>W</em>e can help.</em>
<br />
Contact us at: <i>{initParam.mainEmail}</i>
<br />
<%@ include file="Footer.html" %>
</body>
</html>
```

3. The Footer file ("Footer.jsp")

```html
<a href="index.html">home page</a>
```
Customizing the included content with `<jsp:param>`

OK, so you’ve got a header that’s supposed to appear the same way on every page. But what if you want to customize part of the header? What if you want, say, a context-sensitive subtitle that’s part of the header, but that changes depending on the page?

You have a couple options. 

- **The dumb way**: put the subtitle information into the main page, as, say, the first thing in your page after the include for the header.
- **The smarter way**: pass the subtitle information as a new request parameter to the included page!

*Why that’s cool:* if the subtitle information is supposed to be part of the header, but it’s a part that changes, you still want the header part of the template to make the decision about how that subtitle should appear in the final page. In other words, let the person who designed the header decide how the subtitle should be rendered!

**JSP that does the include**

```jsp
<html><body>

<jsp:include page="Header.jspf">

  <jsp:param name="subTitle" value="We take the sting out of SOAP." />

</jsp:include>

</body></html>
```

**The included header that USES the new param (“Header.jspf”)**

```jsp
<em src="/images/Web-Services.jpg" > <br>
<em> <s> layoffs </s> <em> <s>broadcat</s> <em>
</em> <br>
```

Note: this idea of params doesn’t make any sense with the include directive (which is not dynamic), so it applies ONLY to the `<jsp:include>` standard action.
This got me thinking... if I can include one JSP in another, what if I wanted to forward from one JSP to another? If the client gets to my page and hasn’t logged in, I want to send him to a different page...

The `<jsp:forward>` standard action

You can forward from one JSP to another. Or from one JSP to a servlet. Or from one JSP to any other resource in your web app.

Of course, you don’t usually want to do this in production, because if you’re using MVC, the View is supposed to be the View! And the View has no business doing control logic. In other words, it shouldn’t be the View’s job to figure out if the guy is logged in or not—someone else should have made that decision (the Controller), before deciding to forward to the View.

But let’s suspend all that good MVC judgement for the time being, and see how we could do it, if we were to forward from a JSP page to something else.

Why bother if you’ll never do it? Well, you might one day stumble on a problem where `<jsp:forward>` is a useful solution. More importantly, like a lot of what’s in the book (and the exam), the use of `<jsp:forward>` is out there. Lurking in gazillions of JSPs that you might one day find yourself maintaining (or ideally refactoring).
using \texttt{<jsp:forward/>}

A conditional forward...

So imagine you’re a JSP and you assume you’re being called from a request that includes a \texttt{userName} parameter. Since you’re counting on that parameter, you want to first check that the \texttt{userName} parameter isn’t null. If it’s not, no problem—finish the response. But if the \texttt{userName} parameter is null, you want to stop right here and turn the whole request over to something else—like a different JSP that will ask for the \texttt{userName}.

For now, we know we can do it with scripting:

\textbf{JSP with a conditional forward (Hello.jsp)}

```html
<html><body>
Welcome to our page!

\texttt{<\% if (request.getParameter("userName") == null) \{
  
  \texttt{<jsp:forward page="HandleIt.jsp" />}

\}\%>}

Hello ${param.userName}

</body></html>
```

\textbf{JSP to which the request is forwarded (HandleIt.jsp)}

```html
<html><body>
We’re sorry... you need to log in again.

\texttt{<form action="Hello.jsp" method="get">}
\texttt{Name: <input name="userName" type="text">}
\texttt{<input name="Submit" type="submit">}
\texttt{</form>}

</body></html>
```
How it runs...

The first time you request the Hello.jsp, the JSP does the conditional test, discovers there’s no value for userName, and forwards to the HandleIt.jsp. Assuming the user types a name into the name input field, the second request won’t do the forward, since the userName request parameter has a non-null value.

First request for Hello.jsp

We’re sorry...you need to log in again.
Name: Johannes Submit

Second request for Hello.jsp

Welcome to our page!
Hello Johannes

How come the “Welcome to our page!” text didn’t print out the first time?
With `<jsp:forward>`, the buffer is cleared BEFORE the forward

When a forward happens, the resource to which the request is forwarded starts with a clear response buffer! In other words, anything written to the response before the forward happens is thrown out.

Q: This makes sense if the page is buffered... because what you write is sent to the buffer, and the Container just clears the buffer. But what if you commit the response BEFORE you do the forward? Like, what happens if you write something and then call `flush()` on the object?

A: OK, we know you’re just asking this out of intellectual curiosity since it would be a phenomenally stupid and pointless thing to do. But you know that.

But you also know that weird things can still be on the exam, since your too-lazy-to-learn-it co-worker might just put something this crazy into his code, in which case you better get used to it.

You can probably think through the answer, though. If you write something like:

```
<html><body>
Welcome to our page!

<% out.flush(); %>
<% if (request.getParameter("userName") == null) {
  %>
  Hello ${param.userName}
<% } %>
</body></html>
```

The Container dutifully commits (sends) “Welcome to our page!” as the response and then the Container sees the forward. Uh-oh. Too late. And an `IllegalStateException` happens.

Except nobody will see the exception! The client just sees “Welcome to our page!... and nothing else. The forward throws an exception but it’s too late for the Container to take back the response, so the client sees what was flushed, and that’s it. The forward doesn’t happen, the rest of the current page doesn’t happen. End of story for that page. So never do a flush-and-forward!

```
412 chapter 8
```
She doesn’t know about JSTL tags

When you need more functionality, something beyond what you can get with the standard actions or EL, you don’t have to resort to scripting. In the next chapter, you’ll learn how to use the JSP Standard Tag Library 1.1 (JSTL 1.1) to do just about everything you’ll ever need, using a combination of tags and EL. Here’s a sneak peek of how to do our conditional forward without scripting:

```jsp
<%@ taglib prefix="c" uri="http://java.sun.com/jsp/jstl/core" %>
<html>
<body>
Welcome to our page:

```jstl
<c:if test="${empty param.userName}">
  <jsp:forward page="HandleIt.jsp"/>
</c:if>

Hello ${param.userName}
</body>
</html>
```

declares a taglib directive that names the library where the tags live.

This replaces the scriptlet if test

By the way... you probably won’t be able to run this yet because you don’t have JSTL in your web app. We’ll do that in the next chapter.
**Bean-related standard action review**

- The `<jsp:useBean>` standard action defines a variable that holds a reference to either an existing bean or, if the bean doesn’t already exist, a new bean.
- The `<jsp:useBean>` MUST have an “id” attribute which declares the variable name that’ll be used in this JSP to refer to the bean.
- If you don’t include a “scope” attribute with `<jsp:useBean>`, the scope defaults to page scope.
- The “class” attribute is optional, and it declares the class type that will be used if a new bean is created. The type must be public, non-abstract, and have a public no-arg constructor.
- If you put a “type” attribute in `<jsp:useBean>`, it must be a type to which the bean can be cast.
- If you have a “type” attribute but do NOT have a “class” attribute, the bean must already exist, since you haven’t specified the class type that should be instantiated for the new bean.
- The `<jsp:useBean>` tag can have a body, and anything in the body runs ONLY if a new bean is created as a result of `<jsp:useBean>` (which means no bean with that “id” was found in the specified (or default) scope).
- The main purpose of the body of `<jsp:useBean>` is to set the new bean’s properties, using `<jsp:setProperty>`.
- `<jsp:setProperty>` must have a name attribute (which will match the “id” from `<jsp:useBean>`), and a “property” attribute. The “property” attribute must be either an actual property name or the wildcard “*”.
- If you don’t include a “value” attribute, the Container will set the property value only if there’s a request parameter with a name that matches the property name. If you use the wildcard (*) for the “property” attribute, the Container will set the value of all properties that have a matching request parameter name. (Other properties won’t be affected.)
- If the request parameter name is different from the property name but you want to set the value of the property equal to the request parameter value, you can use the “param” attribute in the `<jsp:setProperty>` tag.
- If you specify a “type” attribute in `<jsp:useBean>`, you can set properties in `<jsp:setProperty>` ONLY on properties of the “type”, but NOT on properties that exist only in the actual “class” type. (In other words, polymorphism and normal Java type rules apply.)
- Property values can be Strings or primitives, and the `<jsp:setProperty>` standard action will do the conversions automatically.
The include review

**BULLET POINTS**

- You can build a page with reusable components using one of two include mechanisms—the `include` directive or the `<jsp:include>` standard action.
- The `include` directive does the include at translation time, only once. So the `include` directive is considered the appropriate mechanism for including content that isn’t likely to change after deployment.
- The `include` directive essentially copies everything from within the included file and pastes it into the page with the include. The Container combines all the included files and compiles just one file for the generated servlet. At runtime, the page with the include runs exactly as though you had typed all the source into one file yourself.
- The `<jsp:include>` standard action includes the response of the included page into the original page at runtime. So the include standard action is considered appropriate for including content that may be updated after deployment, while the include directive is not.
- Either mechanism can include dynamic elements (JSP code with EL expressions, for example) as well as static HTML pages.
- The `include` directive is the only position-sensitive directive; the included content is inserted into the page at the exact location of the directive.
- The attributes for the `include` directive and the `include` standard action are inconsistently named—the directive uses “file” as the attribute while the standard action uses a “page” attribute.
- In your reusable components, be sure to strip out the opening and closing tags, which not all browsers can handle. Design and construct your reusable pieces knowing that they’ll be included/inserted into something else.
- You can customize an included file by setting (or replacing) a request parameter using the `<jsp:param>` standard action inside the body of a `<jsp:include>`.
- We didn’t show it in this chapter, but the `<jsp:param>` can be used inside the body of a `<jsp:forward>` tag as well.
- The ONLY places where a `<jsp:param>` makes sense are within a `<jsp:include>` or a `<jsp:forward>` standard action.
- If the param name used in `<jsp:param>` already has a value as a request parameter, the new value will overwrite the previous one. Otherwise, a new request parameter is added to the request.
- The included resource has some limitations: it cannot change the response status code or set headers.
- The `<jsp:forward>` standard action forwards the request (just using a RequestDispatcher) to another resource from the same web app.
- When a forward happens, the response buffer is cleared first. The resource to which the request was forwarded gets to start with a clean output. So anything written to the response before the forward will be thrown away.
- If you commit the response before the forward (by calling out.flush()), for example), the client will be sent whatever was flushed, but that’s it. The forward won’t happen, and the rest of the original page won’t be processed.
exercise answers

BE the Container
ANSWERS

Look at this standard action:

```jsp
<jsp:useBean id="person" type="foo.Employee" />
<jsp:setProperty name="person" property="name" value="Fred" />
</jsp:useBean>
Name is: <jsp:getProperty name="person" property="name" />
```

What happens if the servlet code looks like:

```
foo.Person p = new foo.Employee();
p.setName("Evan");
request.setAttribute("person", p);
```

FAILS at request time! The "person" attribute is stored at request scope, so the `<jsp:useBean>` tag won't work since it specifies only a type. The Container KNOWS that if you have only a type specified, there MUST be an existing bean attribute of that name and scope.

What happens if the servlet code looks like:

```
foo.Person p = new foo.Person();
p.setName("Evan");
request.setAttribute("person", p);
```

Actually, this servlet fails to compile. We cheated a little, since on this question it isn't "Be the Container", it's more like "Be the COMPILER".

What happens if the servlet code looks like:

```
foo.Employee p = new foo.Employee();
p.setName("Evan");
request.setAttribute("person", p);
```

This works fine, and prints out "Evan". Remember, the code INSIDE the body of `<jsp:useBean>` will NEVER run, since we specified a type without class.
Mock Exam Chapter 8

1
Given an HTML form that uses checkboxes to allow a user to select multiple values for a parameter called hobbies.

Which EL expressions evaluate to the first value of the hobbies parameter? (Choose all that apply)

- A. ${param.hobbies}
- B. ${paramValue.hobbies}
- C. ${paramValues.hobbies[0]}
- D. ${paramValues.hobbies[1]}
- E. ${paramValues[hobbies][0]}
- F. ${paramValues[hobbies][1]}

2
Given that a web application stores the webmaster email address in the servlet context initialization parameter called master-email.

Which retrieves that value? (Choose all that apply)

- A. `<a href="mailto:${initParam.master-email}">email me</a>`
- B. `<a href="mailto:${contextParam.master-email}">email me</a>`
- C. `<a href="mailto:${initParam.'master-email'}">email me</a>`
- D. `<a href="mailto:${contextParam.'master-email'}">email me</a>`
mock exams

3. Given the following Java class:

```java
package com.mycompany;
public class MyFunctions {
  public static String hello(String name) {
    return "Hello " + name;
  }
}
```

This class represents the handler for a function that is part of a tag library.

```xml
<%@ taglib uri="http://mycompany.com.tags" prefix="comp" %>
```

Which Tag Library Descriptor entry defines this custom function so that it can be used in an EL expression?

- A. `<taglib>
  ...
  <tag>
    <tag-name>Hello</tag-name>
    <tag-class>com.mycompany.MyFunctions</tag-class>
    <body-content>JSP</body-content>
  </tag>
</taglib>`

- B. `<taglib>
  ...
  <function>
    <name>Hello</name>
    <function-class>com.mycompany.MyFunctions</function-class>
    <function-signature>java.lang.String hello(java.lang.String)
  </function>
</taglib>`

- C. `<web-app>
  ...
  <servlet>
    <servlet-name>hello</servlet-name>
    <servlet-class>com.mycompany.MyFunctions</servlet-class>
  </servlet>
</web-app>`

- D. `<taglib>
  ...
  <function>
    <name>Hello</name>
    <function-class>com.mycompany.MyFunctions</function-class>
    <function-signature>hello(java.lang.String)</function-signature>
  </function>
</taglib>`
4

Given:

```java
package com.example;
public class TheBean {
  private int value;
  public TheBean() { value = 42; }
  public int getValue() { return value; }
  public void setValue(int v) { value = v; }
}
```

Assuming no instances of TheBean have been created yet, which JSP standard action statements create a new instance of this bean and store it in the request scope? (Choose all that apply.)

- A. `<jsp:useBean name="myBean" type="com.example.TheBean" />`
- B. `<jsp:makeBean name="myBean" type="com.example.TheBean" />`
- C. `<jsp:useBean id="myBean" class="com.example.TheBean" scopes="request" />`
- D. `<jsp:makeBean id="myBean" class="com.example.TheBean" scopes="request" />`

5

Given a Model 1 architecture in which a JSP page handles all of the controller functions, that JSP controller needs to dispatch the request to another JSP page. Which standard action code will perform this dispatch?

- A. `<jsp:forward page="view.jsp" />`
- B. `<jsp:forward file="view.jsp" />`
- C. `<jsp:dispatch page="view.jsp" />`
- D. `<jsp:dispatch file="view.jsp" />`
mock exams

Given:

```java
<% java.util.List list = new java.util.ArrayList();
list.add("a");
list.add("2");
list.add("c");
request.setAttribute("list", list);
request.setAttribute("listIdx", "1");
%>
<-- insert code here -->
```

Which, inserted at line 18, are valid and evaluate to c? (Choose all that apply)

- A. `$(list.2)`
- B. `$(list[2])`
- C. `$(list.listIdx+1)`
- D. `$(list[listIdx+1])`
- E. `$(list['listIdx' + 1])`
- F. `$(list[list['listIdx']])`

Which statements about the . (dot) and [] EL operators are true? (Choose all that apply)

- A. `$(foo.bar)` is equivalent to `$(foo[bar])`
- B. `$(foo.bar)` is equivalent to `$(foo["bar"])`
- C. `$(foo["5"])` is valid syntax if `foo` is a `Map`
- D. `$(header.User-Agent)` is equivalent to `$(header[User-Agent])`
- E. `$(header.User-Agent)` is equivalent to `$(header["User-Agent"])`
- F. `$(foo[5])` is valid syntax if `foo` is a `List` or an array
Given a JSP page with the line:

```
$(101 % 10)
```

What will be displayed?

- A. 1
- B. 10
- C. 1001
- D. 101 % 10
- E. $(101 % 10)

---

Given:

10. `$(param.firstname)`
11. `$(param.middleName)`
12. `$(param.lastname)`
13. `$(paramValues.lastname[0])`

Which describes the output produced by this portion of a JSP page when passed the query string `?firstname=John&lastname= Doe`?

- A. John Doe
- B. John Doe Doe
- C. John null Doe
- D. John null Doe Doe
- E. A null pointer exception will be thrown.

---

Which show valid usage of EL implicit variables? (Choose all that apply.)

- A. `$(cookies.foo)`
- B. `$(initParam.foo)`
- C. `$(pageContext.foo)`
- D. `$(requestScope.foo)`
- E. `$(header["User-Agent"])`
- F. `$(requestDispatcher.foo)`
- G. `$(pageContext.request.requestURI)`
mock exams

11. Which are true about the `<jsp:useBean>` standard action? (Choose all that apply.)
   - A. The `id` attribute is optional.
   - B. The `scope` attribute is required.
   - C. The `scope` attribute is optional and defaults to `request`.
   - D. Either the `class` or `type` attributes may be specified, but at least one.
   - E. It is valid to include both the `class` attribute and the `type` attribute, even if their values are NOT the same.

12. How would you include dynamic content in a JSP, similar to a server-side include (SSI)? (Choose all that apply.)
   - A. `<%@ include file="/segments/footer.jspf" %>`
   - B. `<jsp:forward page="/segments/footer.jspf" />`
   - C. `<jsp:include page="/segments/footer.jspf" />`
   - D. `RequestDispatcher dispatcher = request.getRequestDispatcher("/segments/footer.jspf"); dispatcher.include(request,response);`

13. In an HTML page with a rich, graphical layout, which JSP standard action can be used to import an image file into the JSP page?
   - A. `<jsp:image pages="logo.png" />`
   - B. `<jsp:image file="logo.png" />`
   - C. `<jsp:include page="logo.png" />`
   - D. `<jsp:include file="logo.png" />`
   - E. This CANNOT be done using a JSP standard action.
Chapter 8. Script-free pages

Given:
1. package com.example;
2. public class MyFunctions {
3.   public static String repeat(int x, String str) {
4.     // method body
5.   }
6. }

and given the JSP:
1. <%= taglib url="/WEB-INF/myfuncts" prefix="my" %>
2. <!-- insert code here -->

Which, inserted at line 2 in the JSP, is a valid EL function invocation?

- A. ${repeat(2, "420")}
- B. ${repeat("2", "420")}
- C. ${my:repeat(2, "420")}
- D. ${my:repeat("2", "420")}
- E. A valid invocation CANNOT be determined.

Given:
10. public class MyBean {
11.   private java.util.Map params;
12.   private java.util.List objects;
13.   private String name;
14.   public java.util.Map getParams() { return params; }
15.   public String getName() { return name; }
16.   public java.util.List getObjects() { return objects; }
17. }

Which will cause errors (assume that an attribute named mybean can be found, and is of type MyBean)? (Choose all that apply.)

- A. ${mybean.name}
- B. ${mybean["name"]}
- C. ${mybean.objects.a}
- D. ${mybean["params"].a}
- E. ${mybean.params["a"]}
- F. ${mybean["objects"].a}
mock exams

Given a JSP page:
1. The user has sufficiently logged in or out:
   2. `$(param.login) or param.loggedOut`.
If the request includes the query string "logout=true", what will be this statement’s displayed value?
   - A. The user has sufficiently logged in or out: false.
   - B. The user has sufficiently logged in or out: true.
   - C. The user has sufficiently logged in or out: `$(param.login) or param.loggedOut`.
   - D. The user has sufficiently logged in or out: param.login or param.loggedOut.
   - E. The user has sufficiently logged in or out: true.

Which about EL access operators are true? (Choose all that apply.)
   - A. Anywhere the . (dot) operator is used, the [] could be used instead.
   - B. Anywhere the [] operator is used, the (dot) could be used instead.
   - C. If the . (dot) operator is used to access a bean property but the property doesn’t exist, then a runtime exception is thrown.
   - D. There are some situations where the . (dot) operator must be used and other situations where the [] operator must be used.

The following code fragment appears in a JSP page:

```jsp
<jsp:include page="/jspf/header.html"/>
```

The JSP page is part of a web application with the context root myapp. Given that the application’s top level directory is myapp, what is the path to the header.html file?
   - A. /header.html
   - B. /jspf/header.html
   - C. /myapp/jspf/header.html
   - D. /includes/jspf/header.html
Given an HTML form that uses checkboxes to allow a user to select multiple values for a parameter called `hobbies`.

Which EL expressions evaluate to the first value of the `hobbies` parameter? (Choose all that apply.)

- Option A. `${param.hobbies}`
- Option B. `${paramValue.hobbies}`
- Option C. `${paramValues.hobbies[0]}`
- Option D. `${paramValues.hobbies[1]}`
- Option E. `${paramValues[hobbies][0]}`
- Option F. `${paramValues[hobbies][1]}`

Given that a web application stores the webmaster email address in the servlet context initialization parameter called `master-email`.

Which retrieves that value? (Choose all that apply.)

- Option A. `<a href="mailto:${initParam.master-email}">email me</a>`
- Option B. `<a href="mailto:${contextParam.master-email}">email me</a>`
- Option C. `<a href="mailto:${initParam['master-email']}">email me</a>`
- Option D. `<a href="mailto:${contextParam['master-email']}">email me</a>`

Option B is incorrect because there is no `paramValue` implicit variable.
Option D is incorrect, arrays are 0 indexed.
Option E and F have incorrect syntax.
Option A is trying to subtract email from master.
Option B, there is no `contextParam` implicit variable.
Option D, there is no `contextParam` implicit variable.
mock answers

Given the following Java class:

```java
package com.mycompany;
public class MyFunctions {
    public static String hello(String name) {
        return "Hello " + name;
    }
}
```

This class represents the handler for a function that is part of a tag library.

```xml
<%@ taglib uri="http://mycompany.com.tags" prefix="comp" %>
```

Which Tag Library Descriptor entry defines this custom function so that it can be used in an EL expression?

- Option A: `<taglib>`
  ```xml
  ...
  <tag>
  <tag-name>Hello</tag-name>
  <tag-class>com.mycompany.MyFunctions</tag-class>
  <body-content>JSP</body-content>
  </tag>
  </taglib>
  ```

- Option B: `<taglib>`
  ```xml
  ...
  <function>
  <name>Hello</name>
  <function-class>com.mycompany.MyFunctions</function-class>
  <function-signature>java.lang.String hello(java.lang.String)</function-signature>
  </function>
  </taglib>
  ```

- Option C: `<web-app>`
  ```xml
  ...
  <servlet>
  <servlet-name>hello</servlet-name>
  <servlet-class>com.mycompany.MyFunctions</servlet-class>
  </servlet>
  </web-app>
  ```

- Option D: `<taglib>`
  ```xml
  ...
  <function>
  <name>Hello</name>
  <function-class>com.mycompany.MyFunctions</function-class>
  <function-signature>hello(java.lang.String)</function-signature>
  </function>
  </taglib>
  ```

426 chapter 8

4

Given:

1. package com.example;
2. public class TheBean {
3.     private int value;
4.     public TheBean() { value = 42; }
5.     public int getValue() { return value; }
6.     public void setValue(int v) { value = v; }
7. }

Assuming no instances of TheBean have been created yet, which JSP standard action statements create a new instance of this bean and store it in the request scope? (Choose all that apply)

- Option A is invalid because the type attribute is NOT used to create a new instance and the scope attribute must be specified (or defaults to page).
- Option B is invalid for all of the above reasons plus jsp:makeBean is NOT a real tag.
- Option D is invalid because jsp:makeBean is NOT a real tag.

5

Given a Model 1 architecture in which a JSP page handles all of the controller functions, that JSP controller needs to dispatch the request to another JSP page.

Which standard action code will perform this dispatch?

- Option A is correct (pg 1-110).
- Option B is invalid because the forward action has no file attribute
- Options C and D are invalid because there is no dispatch action.
mock answers

6 Given:
11. `<% java.util.List list = new java.util.ArrayList();
12. list.add("a");
13. list.add("2");
14. list.add("c");
15. request.setAttribute("list", list);
16. request.setAttribute("listIdx", "1");
17. %>
18. `<%-- insert code here --%>
Which, inserted at line 18, are valid and evaluate to c? (Choose all that apply)

- A. `${list.2}`
- B. `${list[2]}`
- C. `${list.listIdx+1}`
- D. `${list[0]}`
- E. `${list["listIdx' + 1]}`
- F. `${list[list["listIdx'"]}]`

7 Which statements about the . (dot) and [] EL operators are true? (Choose all that apply)
- A. `${foo.bar}` is equivalent to `${foo[bar]}`
- B. `${foo.bar}` is equivalent to `${foo["bar"]}`
- C. `${foo["5"]}` is valid syntax if foo is a Map
- D. `${header.User-Agent}` is equivalent to `${header[User-Agent]}`
- E. `${header.User-Agent}` is equivalent to `${header["User-Agent"]}`
- F. `${foo[5]}` is valid syntax if foo is a List or an array

---

Chapter 8. Script-free pages

Options A and C are incorrect because the dot operator cannot be used with a primitive.

Options E is incorrect because `${listIdx' + 1}` becomes a String.

Option A is incorrect because it should be `${foo.bar'}`.

Options D and E are incorrect because of the dash in User-Agent. Only `header["User-Agent"]` will work.
Given a JSP page with the line:

$$\{\text{101} \% \text{10}\}$$

What will be displayed?

- Option A is correct. The modulus operator returns the remainder of a division operation.

- Option B is incorrect. The variable is "cookie".

- Option C is incorrect because pageContext is not a Map and it doesn't have a "foo" property.

- Option D is invalid because line 13 prints the user's last name as well.

- Option E is invalid because line 13 prints the user's last name as well.

Which show valid usage of EL implicit variables? (Choose all that apply.)

- Option A is incorrect because the variable is "cookie".

- Option B is incorrect because pageContext is NOT a Map and it doesn't have a "foo" property.

- Option C is incorrect because this is NOT an implicit object.

- Option D is incorrect because this is NOT an implicit object.

- Option E is incorrect because this is NOT an implicit object.

- Option F is incorrect because this is NOT an implicit object.

- Option G is incorrect because this is NOT an implicit object.

- Option H is incorrect because this is NOT an implicit object.

- Option I is incorrect because this is NOT an implicit object.

- Option J is incorrect because this is NOT an implicit object.

- Option K is incorrect because this is NOT an implicit object.

- Option L is incorrect because this is NOT an implicit object.

- Option M is incorrect because this is NOT an implicit object.

- Option N is incorrect because this is NOT an implicit object.

- Option O is incorrect because this is NOT an implicit object.

- Option P is incorrect because this is NOT an implicit object.

- Option Q is incorrect because this is NOT an implicit object.

- Option R is incorrect because this is NOT an implicit object.

- Option S is incorrect because this is NOT an implicit object.

- Option T is incorrect because this is NOT an implicit object.

- Option U is incorrect because this is NOT an implicit object.

- Option V is incorrect because this is NOT an implicit object.

- Option W is incorrect because this is NOT an implicit object.

- Option X is incorrect because this is NOT an implicit object.

- Option Y is incorrect because this is NOT an implicit object.

- Option Z is incorrect because this is NOT an implicit object.

You are here → 429
mock answers

11 Which are true about the <jsp:useBean> standard action? (Choose all that apply.)

- Option A is incorrect because id is required.
- Option B and C are incorrect because scope is optional and defaults to page.
- Option E is valid to include both the class attribute and the type attribute, even if their values are NOT the same.

12 How would you include dynamic content in a JSP, similar to a server-side include (SSI)? (Choose all that apply.)

- Option A is incorrect because it uses an include directive, which is for static includes that happen at translation time.
- Option D would be correct if it was a scriptlet: it functionally does the same thing as option C, but its syntax is only used by servlets.

13 In an HTML page with a rich, graphical layout, which JSP standard action can be used to import an image file into the JSP page?

- Option A and B are invalid because there is no image standard action.
- Option C is invalid, not because the syntax of the include action is wrong, but because it does not make sense to import the binary data of the image file into the JSP content.
- Option D is invalid because the include action does not take a file attribute.
- Option E is invalid because it is NOT possible to import the contents of any binary file into a JSP page, which generates an HTML response.

This is a tricky question because it is NOT possible to import the contents of any binary file into a JSP page, which generates an HTML response.
scriptless JSPs

Given:

1. package com.example;
2. public class MyFunctions {
3.   public static String repeat(int x, String str) {
4.      // method body
5.   }
6. }

and given the JSP:

1. <%@ taglib uri="/WEB-INF/myfuncs" prefix="my" %>
2. <!-- insert code here -->

Which, inserted at line 2 in the JSP, is a valid EL function invocation?

- Option C is correct. The necessary mapping information is NOT known.

Given:

10. public class MyBean {
11.   private java.util.Map params;
12.   private java.util.List objects;
13.   private String name;
14.   public java.util.Map getParams() { return params; }
15.   public String getName() { return name; }
16.   public java.util.List getObjects() { return objects; }
17. }

Which will cause errors (assume that an attribute named mybean can be found, and is of type MyBean)? (Choose all that apply.)

- Option C and F will cause errors.
- Options C and F will cause errors.
- Options C and F will cause errors.
- Options C and F will cause errors.

mock answers

16. Given a JSP page:

1. The user has sufficiently logged in or out: 
   - $(param.loggedin or param.logedOut).

   If the request includes the query string “loggedOut=true”, what will be this statement’s displayed value?
   - A. The user has sufficiently logged in or out: false.
   - B. The user has sufficiently logged in or out: true.
   - C. The user has sufficiently logged in or out: $(param.loggedin or param.logedOut).
   - D. The user has sufficiently logged in or out: param.loggedin or param.logedOut.
   - E. The user has sufficiently logged in or out: or true.

Which about EL access operators are true? (Choose all that apply.)

- A. Anywhere the . (dot) operator is used, the [] could be used instead.
- B. Anywhere the [] operator is used, the . (dot) could be used instead.
- C. If the .. (dot) operator is used to access a bean property but the property doesn’t exist, then a runtime exception is thrown.
- D. There are some situations where the .. (dot) operator must be used and other situations where the [] operator must be used.

17. The following code fragment appears in a JSP page:

<jsp:include page="/jspf/header.html"/>

The JSP page is part of a web application with the context root myapp. Given that the application’s top level directory is myapp, what is the path to the header.html file?

- A. /header.html
- B. /jspf/header.html
- C. /myapp/jspf/header.html
- D. /includes/jspf/header.html

18. (JSP v2.0 section 5.4)

The path /jspf/header.html when used as the value of the <jsp:include action’s page attribute is relative to the web application, so a leading back slash (/) means “begin at the application’s top level.”
9 using JSTL

Custom tags are powerful

You mean, I spent all this time writing scriptlets for the things I can't do with EL and standard actions, when I could have used JSTL?

Sometimes you need more than EL or standard actions.

What if you want to loop through the data in an array, and display one item per row in an HTML table? You know you could write that in two seconds using a for loop in a scriptlet. But you're trying to get away from scripting. No problem. When EL and standard actions aren't enough, you can use custom tags. They're as easy to use in a JSP as standard actions. Even better, someone's already written a pile of the ones you're most likely to need, and bundled them into the JSP Standard Tag Library (JSTL). In this chapter we'll learn to use custom tags, and in the next chapter we'll learn to create our own.
Chapter 9. Custom tags are powerful

Objectives

Building JSP pages using tag libraries

9.1 Describe the syntax and semantics of the `taglib` directive: for a standard tag library, for a library of Tag Files.

9.2 Given a design goal, create the custom tag structure to support that goal.

9.3 Identify the tag syntax and describe the action semantics of the following JSP Standard Tag Library (JSTL v1.1) tags: (a) core tags: out, set, remove, and catch, (b) conditional tags: if, choose, when, and otherwise, (c) iteration tags: forEach, and (d) URL-related: url.

Coverage Notes:

All of the objectives in this section are covered in this chapter, although some of the content is covered again in the next chapter (Developing Custom Tags).

Installing the JSTL 1.1

The JSTL 1.1 is NOT part of the JSP 2.0 specification! Having access to the Servlet and JSP API's doesn't mean you have access to JSTL.

Before you can use JSTL, you need to install the `jstl.jar` file into the WEB-INF/lib directory of your web app. That means each web app needs a copy.

In Tomcat 5, the JSTL is already in the example applications that ship out-of-the-box with Tomcat, so all you need to do is copy it out of one directory and into your own WEB-INF/lib directory.

Copy the JSTL from the Tomcat examples at:

webapps.jsp-examples/WEB-INF/lib/jstl.jar

And place it in your own web app's WEB-INF/lib directory.
EL and standard actions are limited

What happens when you bump into a brick wall? You can go back to scripting, of course—but you know that’s not the path.

Developers usually want way more standard actions or—even better—the ability to create their own actions.

That’s what custom tags are for. Instead of saying `<jsp:getProperty>`, you want to do something like `<my:doCustomThing>`. And you can.

But it’s not that easy to create the support code that goes behind the tag. For the JSP page creator, custom tags are much easier to use than scripting. For the Java programmer, however, building the custom tag handler (the Java code invoked when a JSP uses the tag) is tougher.

Fortunately, there’s a standard library of custom tags known as the JSP Standard Tag Library (JSTL 1.1). Given that your JSP shouldn’t be doing a bunch of business logic anyway, you might find that the JSTL (combined with EL) is all you’ll ever need. Still, there could be times when you need something from, say, a custom tag library developed specifically for your company.

In this chapter, you’ll learn how to use the core JSTL tags, as well as custom tags from other libraries. In the next chapter, we’ll learn how to actually build the classes that handle calls to the custom tags, so that you can develop your own.
the `<c:forEach>` tag

Looping without scripting

Imagine you want something that loops over a collection (say, an array of catalog items), pulls out one element at a time, and prints that element in a dynamically-generated table row. You can’t possibly hard-code the complete table—you have no idea how many rows there will be at runtime, and of course you don’t know the values in the collection. The `<c:forEach>` tag is the answer. This does require a very slight knowledge of HTML tables, but we’ve included notes here for those who aren’t familiar with the topic.

By the way, on the exam you are expected to know how to use `<c:forEach>` with tables.

Servlet code

```java
...  
String[] movieList = {"Amelie", "Return of the King", "Mean Girls"};  
request.setAttribute("movieList", movieList);  
...
```

What you want

![Movie list: Amelie, Return of the King, Mean Girls](image)

In a JSP, with scripting

```jsp
<table>
  <c:forEach items = (String[]) request.getAttribute("movieList")>
    <tr>
      <td>${var}</td>
    </tr>
  </c:forEach>
</table>
```

436 chapter 9
<c:forEach>

The `<c:forEach>` tag from the JSTL is perfect for this—it gives you a simple way to iterate over arrays and collections.

**JSP code**

```jsp
<%@ taglib prefix="c" uri="http://java.sun.com/jsp/jstl/core" %>
<html><body>
<br>
Movie list:<strong><br></strong>
<table>
  <c:forEach var="movie" items="${movieList}">
    <tr>
      <td>${movie}</td>
    </tr>
  </c:forEach>
</table>
</body></html>
```

**Crash refresher on HTML tables**

<table>
<thead>
<tr>
<th>&lt;tr&gt;</th>
<th>&lt;td&gt;data for this cell&lt;/td&gt;</th>
<th>&lt;td&gt;data for this cell&lt;/td&gt;</th>
<th>&lt;td&gt;data for this cell&lt;/td&gt;</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;tr&gt;</td>
<td>&lt;td&gt;data for this cell&lt;/td&gt;</td>
<td>&lt;td&gt;data for this cell&lt;/td&gt;</td>
<td>&lt;td&gt;data for this cell&lt;/td&gt;</td>
<td>...</td>
</tr>
<tr>
<td>&lt;tr&gt;</td>
<td>&lt;td&gt;data for this cell&lt;/td&gt;</td>
<td>&lt;td&gt;data for this cell&lt;/td&gt;</td>
<td>&lt;td&gt;data for this cell&lt;/td&gt;</td>
<td>...</td>
</tr>
</tbody>
</table>

Tables are pretty straightforward. They’ve got **cells**, arranged into **rows** and **columns**, and the data goes inside the cells. The trick is telling the table how many rows and columns you want.

Rows are defined with the `<tr>` (Table Row) tag, and columns are defined with the `<td>` (Table Data) tag. The number of rows comes from the number of `<tr>` tags, and the number of columns comes from the number of `<td>` tags you put inside the `<tr>` tags.

*Data to print/display goes only inside the `<td>` tags!*

---

**using JSTL**

(We’ll talk about this taglib directive later in the chapter.)

Chapter 9. Custom tags are powerful
**Deconstructing `<c:forEach>`**

The `<c:forEach>` tag maps nicely into a for loop—the tag repeats the body of the tag for each element in the collection (and we use “collection” here to mean either an array or Collection or Map or comma-delimited String).

The key feature is that the tag assigns each element in the collection to the variable you declare with the `var` attribute.

```
<c:forEach var="movie" items="${movieList}">
    ${movie}
</c:forEach>
```

The variable that holds each ELEMENT in the collection. Its value changes with each iteration.

The actual thing to loop over (array, Collection, Map, or a comma-delimited String).

Getting a loop counter with the optional `varStatus` attribute

```
<%=
    varStatus = new javax.servlet.jsp.jstl.core.LoopTagStatus;
%>
<table>
    <c:forEach var="movie" items="${movieList}" varStatus="movieLoopCount">
        <tr>
            <td>Count: ${movieLoopCount.count}</td>
        </tr>
    </c:forEach>
</table>
```

**Chapter 9. Custom tags are powerful**
You can even nest `<c:forEach>` tags

What if you have something like a collection of collections? An array of arrays? You can nest `<c:forEach>` tags for more complex table structures. In this example, we put String arrays into an ArrayList, then make the ArrayList a request attribute. The JSP has to loop through the ArrayList to get each String array, then loop through each String array to print the actual elements of the array.

**Servlet code**

```
String[] movies1 = {"Matrix Revolutions", "Kill Bill", "Boondock Saints"};
String[] movies2 = {"Amelie", "Return of the King", "Mean Girls"};
java.util.List movieList = new java.util.ArrayList();
movieList.add(movies1);
movieList.add(movies2);
request.setAttribute("movies", movieList);
```

**JSP code**

```
<table>
  <c:forEach var="listElement" items="${movies}">
    <c:forEach var="movie" items="${listElement}">
      <tr>
        <td>${movie}</td>
      </tr>
    </c:forEach>
  </c:forEach>
</table>
```

Chapter 9. Custom tags are powerful

the <c:forEach> tag

日常疑问

Q: How did you know that the "varStatus" attribute was an instance of whatever that was, and how did you know that it has a "count" property?

A: Ahhhh... we looked it up.

It's all there in the JSTL 1.1 spec. If you don't have the spec already, go download it NOW (the intro of this book tells you where to get the specs covered on the exam). It is THE reference for all the tags in the JSTL, and tells you all the possible attributes, whether they're optional or required, the attribute type, and any other details on how you use the tag.

Everything you need to know about these tags (for the exam) is in this chapter. But some of the tags have a few more options than we cover here, so you might want to have a look in the spec.

Q: Since you know more than you're telling about this tag... does it give you a way to change the iteration steps? In a real Java for loop, I don't have to do i++, I can do i+=3, for example, to get every third element instead of every element...

A: Not a problem. The <c:forEach> tag has optional attributes for begin, end (in case you want to iterate over a subset of the collection), and step if you want to skip over some elements.

Q: Is the "c" in <c:forEach> a required prefix?

A: Well, some prefix is required, of course; all tags and EL functions must have a prefix to give the Container the namespace for that tag or function name. But you don't HAVE to name the prefix "c". It's just the standard convention for the set of tags in JSTL known as "Core." We recommend using something other than "c" as a prefix, whenever you want to totally confuse the people you work with.

440 chapter 9
Doing a conditional include with `<c:if>`

Imagine you have a page where users can view comments from other users. And imagine that members can also post comments, but non-member guests cannot. You want everyone to get the same page, but you want members to “see” more things on the page. You want a conditional `<jsp:include>` and of course, you don’t want to do it with scripting!

What members see:

```
Member Comments
This site rocks.
This site is cool.
This site is great.
```

What NON-members see:

```
Member Comments
This site rocks.
This site is cool.
This site is great.

We don’t want the “Add…” parts to appear if the client is NOT a member.
```

JSP code

```
<%@ taglib prefix=”c” uri=”http://java.sun.com/jsp/jstl/core” %>
<html>
<body>
<p>Member Comments</p>
<br/>
<p>${commentList}</p>
<br/>
<c:if test=”${userType eq ‘member’}”>
<jsp:include page=”inputComments.jsp”/>
</c:if>
<br/>
</body>
</html>
```

Included page (“inputComments.jsp”)

```
<form action=”commentsProcess.jsp” method=”post”>

Add your comment: <br/>
<textarea name=”input” cols=”40” rows=”10”></textarea> <br/>
<input name=”commentSubmit” type=”button” value=”Add Comment”>
</form>
```
But what if you need an else?

What if you want to do one thing if the condition is true, and a different thing if the condition is false? In other words, what if we want to show either one thing or the other, but nobody will see both? The `<c:if>` on the previous page worked fine because the logic was: everybody sees the first part, and then if the test condition is true, show a little extra.

But now imagine this scenario: you have a car sales web site, and you want to customize the headline that shows up on each page, based on a user attribute set up earlier in the session. Most of the page is the same regardless of the user, but each user sees a customized headline—one that best fits the user’s personal motivation for buying. (We are, after all, trying to sell him a car and become obscenely wealthy.) At the beginning of the session, a form asks the user to choose what’s most important...

At the beginning of the session:

![Image of a form asking about car preferences]

Somewhere later in the session:

![Image of a car details page]

Imagine a web site for a car company. The first page asks the user what he feels is most important. Just like a good salesman, the pages that talk about features of the car will customize the presentation based on the user’s preference, so that each feature of the car looks like it was made with his personal needs in mind...

The user's page is customized a little, to fit his interests.
The `<c:if>` tag won’t work for this

There’s no way to do exactly what we want using the `<c:if>` tag, because it doesn’t have an “else”. We can almost do it, using something like:

**JSP using `<c:if>`, but it doesn’t work right...**

```jsp
<c:if test=""${userPref=='performance'}"">
    Now you can stop even if you <em>don’t</em> drive insanely fast.
</c:if>
<c:if test=""${userPref=='safety'}"">
    Our brakes won’t lock up no matter how bad a driver you are.
</c:if>
<c:if test=""${userPref=='maintenance'}"">
    Lost your tech job? No problem—you won’t have to service these brakes for at least three years.
</c:if>
```

But what happens if `userPref` doesn’t match any of these? There’s no way to specify the default headline. -- --

```jsp
<-- continue with the rest of the page that EVERYONE should see -->
```

The `<c:if>` won’t work unless we’re CERTAIN that we’ll never need a default value. What we really need is kind of an if/else construct:

**JSP with scripting, and it does what we want**

```jsp
<html><body><h2>
<% String pref = (String) session.getAttribute("userPref");
    if (pref.equals("performance")) {
        out.println("Now you can stop even if you <em>don’t</em> drive insanely fast.");
    } else if (pref.equals("safety")) {
        out.println("Our brakes won’t lock up no matter how bad a driver you are.");
    } else if (pref.equals("maintenance")) {
        out.println("Lost your tech job? No problem—you won’t have to service these brakes for at least three years.");
    } else {
        // userPref doesn’t match those, so print the default headline
        out.println("Our brakes are the best.");
    }
</h2></strong>The Brakes</strong> <br>Our advanced anti-lock brake system (ABS) is engineered to give you the ability to steer even as you’re stopping. We have the best speed sensors of any car this size. <br>
</body></html>
```

Yes, we agree with you—there’s nearly always a better approach than chained if tests. But you’re just gonna have to suspend disbelief long enough to learn how this all works....

*you are here* 443
Chapter 9. Custom tags are powerful

the `<c:choose>` tag

I will choose you
when you are ready to give up your obsession with Pilates.
otherwise, I’ll have to go
with Kerey for the synchronized
swim team.

The `<c:choose>` tag and its partners
`<c:when>` and `<c:otherwise>`

```xml
<c:choose>
  <c:when test="${userPref == 'performance'}">
    Now you can stop even if you `<em>`do</em>` drive insanely fast.
  </c:when>
  <c:when test="${userPref == 'safety'}">
    Our brakes will never lock up, no matter how bad a driver you are.
  </c:when>
  <c:when test="${userPref == 'maintenance'}">
    Lost your tech job? No problem—you won’t have to service these brakes
    for at least three years.
  </c:when>
  <c:otherwise>
    Our brakes are the best.
  </c:otherwise>
</c:choose>
```

Note: the `<c:choose>` tag is NOT
required to have a `<c:otherwise>` tag.

No more than ONE of these four bodies
(including the `<c:otherwise>`) will run.
(it’s not like a switch statement—
there’s no fall-through.)

Chapter 9. Custom tags are powerful

**The `<c:set>` tag... so much cooler than `<jsp:setProperty>`**

The `<jsp:setProperty>` tag can only do one thing—set the property of a bean. But what if you want to set a value in a Map? What if you want to make a new entry in a Map? Or what if you simply want to create a new request-scoped attribute?

You get all that with `<c:set>`, but you have to learn a few simple rules. `<c:set>` comes in two flavors: var and target. The var version is for setting attribute variables, the target version is for setting bean properties or Map values. Each of the two flavors comes in two variations: with or without a body. The `<c:set>` body is just another way to put in the value.

### Setting an attribute variable var with `<c:set>`

1. **With NO body**
   - `<c:set var="userLevel" scope="session" value="Cowboy" />`
   - The scope is optional, but is required. You **MUST** specify a value, but you have a choice between putting in a value attribute or putting the value in the tag body (see #2 below).
   - value doesn’t have to be a String—If `$person.dog` evaluates to a Dog object, then “Fido” is of type Dog.

2. **WITH a body**
   - `<c:set var="Fido" value="${person.dog}" />`
   - The body is evaluated and used as the value of the variable.
   - Remember, no slash here when the tag has a body.

---

**If the value evaluates to null, the variable will be REMOVED! That’s right, removed.**

Imagine that for the value (either in the body of the tag or using the value attribute), you use `$person.dog`. If `$person.dog` evaluates to null (meaning there is no person, or person’s dog property is null), then if there is a variable with a name “Fido”, that attribute will be removed! (if you don’t specify a scope, it will be removing at page, then request, etc.). This happens even if the “Fido” attribute was originally set as a Seizing, or a Duck, or a Broccoli.

Key points and gotchas with `<c:set>`

Yes, `<c:set>` is easy to use, but there are a few deal-breakers you have to remember...

- You can never have BOTH the "var" and "target" attributes in a `<c:set>`.
- "Scope" is optional, but if you don’t use it the default is page scope.
- If the "value" is null, the attribute named by "var" will be removed!
- If the attribute named by "var" does not exist, it’ll be created, but only if "value" is not null.
- If the "target" expression is null, the Container throws an exception.
- The "target" is for putting in an expression that resolves to the Real Object. If you put in a String literal that represents the "id" name of the bean or Map, it won’t work. In other words, "target" is not for the attribute name of the bean or Map—it’s for the actual attribute object.
- If the "target" expression is not a Map or a bean, the Container throws an exception.
- If the "target" expression is a bean, but the bean does not have a property that matches "property", the Container throws an exception. But be careful, because the EL expression by itself will NOT cause an exception if the property doesn’t exist. So even though: `$fooBean.notAPROPERTY` won’t cause an exception by itself (it just returns null), if that same "notAPROPERTY" is the value of a "target" attribute, the Container throws an exception.

Q: Why would I use the body version instead of the no-body version? It looks like they both do exactly the same thing.

A: That’s because they do... do the same thing. The body version is just for convenience when you want more room for the value. It might be a long and complex expression, for example, and putting it in the body makes it easier to read.

Q: If I don’t specify a scope, does that mean it will find attributes that are ONLY within page scope, or does it do a search beginning with page scope?

A: If you don’t use the optional "scope" attribute in the tag, and you’re using "var" or "target", the Container will search scopes in the order in which you’ve come to expect—page, then request, then session, then application (context).

If you use the "var" version without a scope, and the Container can’t find an attribute of that name in any of the four scopes, the Container makes a new one in page scope.

Q: Why is the word “attribute” so overloaded? It means both “the things that go inside tags” and “the things that are bound to objects in one of the four scopes.” So you end up with an attribute of a tag whose value is an attribute of the page and...

A: We hear you. But that’s what they’re called. Once again, nobody asked Us. We would have called the bound objects something like, oh, "bound objects!"
the `<c:remove>` tag

I can’t believe you have to use `<c:set>` to remove an attribute. That feels wrong.

We agree with Dick—using a `<c:set>` to remove something feels wrong. (But remember, `<c:set>` does a `<c:remove>` only when you pass in a null value.)

The `<c:remove>` tag is intuitive and simple:

```xml
<c:remove var="userStatus" scope="request"/>
```

The var attribute MUST be a String literal! It can’t be an expression!

The value of userStatus was removed, so nothing prints when the EL expression is used after the `<c:remove>`.

The var attribute MUST be a String literal! It can’t be an expression!

The scope is optional, and like always—page is the default scope.

The var attribute MUST be a String literal! It can’t be an expression!

Chapter 9. Custom tags are powerful

---

**Sharpen your pencil**

**Test your Tag memory**

If you're studying for the exam, don't skip this one.
The answers are at the end of the chapter.

1. Fill in the name of the optional attribute.

   ```xml
   <c:forEach var="movie" items="${movieList}" foo="foo" >
     ${movie}
   </c:forEach>
   ```

2. Fill in the missing attribute name.

   ```xml
   <c:if>${userPref=='safety'"} >
     Maybe you should just walk...
   </c:if>
   ```

3. Fill in the missing attribute name.

   ```xml
   <c:set var="userLevel" scope="session" foo="foo" />
   ```

4. Fill in the missing tag names (two different tag types), and the missing attribute name.

   ```xml
   <c:choose>
     <c:when>${userPref == ‘performance’}">
       Now you can stop even if you <em>do</em> drive insanely fast.
     </c:when>
     <c:otherwise>
       Our brakes are the best.
     </c:otherwise>
   </c:choose>
   ```

the `<c:import>` tag

With `<c:import>`, there are now THREE ways to include content

So far, we’ve used two different ways to add content from another resource into a JSP. But there’s yet another way, using JSTL.

1. The `include` directive

    `<%@ include file="Header.html" %>`

    Static: adds the content from the value of the `file` attribute to the current page at translation time.

2. The `<jsp:include>` standard action

    `<jsp:include page="Header.jsp" />`

    Dynamic: adds the content from the value of the `page` attribute to the current page at request time.

3. The `<c:import>` JSTL tag

    `<c:import url="http://www.wickedlysmart.com/skyler/horse.html" />`

    Dynamic: adds the content from the value of the `URL` attribute to the current page at request time. It works a lot like `<jsp:include>`, but it’s more powerful and flexible.

Do NOT confuse `<c:import>` (a type of include) with the "import" attribute of the page directive (a way to put a Java import statement in the generated servlet).

They all have different attribute names!
(And watch out for "include" vs. "import")

Each of the three mechanisms for including content from another resource into your JSP uses a different word for the attribute. The include directive uses `file`, the `<jsp:include>` uses `page`, and the JSTL `<c:import>` tag uses `url`. This makes sense, when you think about it... but you do have to memorize all three. The directive was originally intended for static layout templates, like HTML headers. In other words, a "file". The `<jsp:include>` was intended more for dynamic content coming from JSPs, so they named the attribute "page" to reflect that. The attribute for `<c:import>` is named for exactly what you give it—a URL! Remember, the first two "includes" can’t go outside the current Container, but `<c:import>` can.
<c:import> can reach OUTSIDE the web app

With <jsp:include> or the include directive, you can include only pages that are part of the current web app. But now with <c:import>, you have the option to pull in content from outside the Container. This simple example shows a JSP on Server A importing the contents of a URL on Server B. At request time, the HTML chunk in the imported file is added to the JSP. The imported chunk uses a reference to an image that is also on Server B.

Server A, the JSP doing the import

```jsp
<%@ taglib prefix="c" uri="http://java.sun.com/jsp/jstl/core" %>
<html>

<br/>
This is my horse.
</body>
</html>
```

Server B, the imported content

The imported file

```html
<img src="http://www.wickedlysmart.com/skylers/horse.gif">
```

The response

This is my horse.

The horse is coming from a completely different web server than the page that contains the text.

“horse.html” and “horse.gif” are both on Server B, a completely different web server from the one with the JSP.

using JSTL
the `<c:import>` tag

**Customizing the thing you include**

Remember in the previous chapter when we did a `<jsp:include>` to put in the layout header (a graphic with some text), but we wanted to customize the subtitle used in the header? We used `<jsp:param>` to make that happen...

1. **The JSP with the `<jsp:include>`**

   ```html
   <html><body>
   
   `<jsp:include pages="Header.jsp">
   
   `<jsp:param name="subTitle" value="We take the sting out of SOAP." />
   
   `<br>
   `<em>Welcome to our Web Services Support Group.</em>
   `<br>
   Contact us at: $[param.mainEmail]
   
   `</body>`
   ```

2. **The included file ("Header.jsp")**

   ```html
   `<img src="images/Web-Services.jpg" />
   `</br>
   `<em><strong>${param.subTitle}</strong></em>`
   `</br>`
   ```

We made the subtitle “We take the sting out of SOAP.” available to the header JSP by setting it as a new request parameter.
Doing the same thing with <c:param>

Here we accomplish the same thing we did on the previous page, but using a combination of <c:import> and <c:param>. You'll see that the structure is virtually identical to the one we used with standard actions.

1. The JSP with the <jsp:include>

```jsp
<%@ taglib prefix="c" uri="http://java.sun.com/jsp/jstl/core" %>
<html><body>
<c:import url="Header.jsp">
    <c:param name="subTitle" value="We take the sting out of SOAP."/>
</c:import>
<br/>
<em>Welcome to our Web Services Support Group.</em> <br>
Contact us at: ${initParam.mainEmail}
</body></html>
```

2. The included file ("Header.jsp")

```jsp
<img src="images/Web-Services.jpg" />
<em><strong>${param.subTitle}</strong></em>
<br/>
```
Chapter 9. Custom tags are powerful

URL rewriting in a JSP

Sorry to change the subject here, but I just noticed a HUGE problem with JSPs. How can you guarantee session tracking from a JSP... without using scripting?

He missed the point. I said "guarantee". My real question is—if the client doesn’t support cookies, how can I get URL rewriting to happen? How can I get the session ID added to the URLs in my JSP?

Session tracking happens automatically with JSPs, unless you explicitly disable it with a page directive that has a session attribute that says sessions="false".

Ahh... he obviously doesn’t know about the <c:url> tag. It does URL rewriting automatically.

454  chapter 9
<c:url> for all your hyperlink needs

Remember way back in our old servlet days when we wanted to use a session? First we had to get the session (either the existing one or a new one). At that point, the Container knows that it’s supposed to associate the client from this request with a particular session ID. The Container wants to use a cookie—it wants to include a unique cookie with the response, and then the client will send that cookie back with each subsequent request. Except one problem... the client might have a browser with cookies disabled. Then what?

The Container will, automatically, fall back to URL rewriting if it doesn’t get a cookie from the client. But with servlets, you STILL have to encode your URLs. In other words, you still have to tell the Container to “append the sessionid to the end of this particular URL...” for each URL where it matters. Well, you can do the same thing from a JSP, using the <c:url> tag.

**URL rewriting from a servlet**

```java
public void doGet(HttpServletRequest request, HttpServletResponse response) throws IOException, ServletException {
    response.setContentType("text/html");
    PrintWriter out = response.getWriter();
    HttpSession session = request.getSession();
    out.println("<html><body>");
    out.println("<a href="" + response.encodeURL("/BeerTest.do") + ">") +"\"click\"/a>);";
    out.println("</body></html>"");
    }
}
```

Add the extra session ID info to this URL.

**URL rewriting from a JSP**

```html
<%@ taglib prefix="c" uri="http://java.sun.com/jsp/jstl/core" %>
<html><body>

This is a hyperlink with URL rewriting enabled.

<a href="<c:url value='/inputComments.jsp' />">Click here</a>

</body></html>
```

*you are here*  455
the `<c:url>` tag

What if the URL needs encoding?

Remember that in an HTTP GET request, the parameters are appended to the URL as a query string. For example, if a form on an HTML page has two text fields—first name and last name—the request URL will stick the parameter names and values on to the end of the request URL. But...an HTTP request won’t work correctly if it contains unsafe characters (although most modern browsers will try to compensate for this).

If you’re a web developer, this is old news, but if you’re new to web development, you need to know that URLs often need to be encoded. URL encoding means replacing the unsafe/reserved characters with other characters, and then the whole thing is decoded again on the server side. For example, spaces aren’t allowed in a URL, but you can substitute a plus sign “+” for the space. The problem is, `<curl>` does NOT automatically encode your URLs!

Using `<curl>` with a query string

Remember, the `<curl>` tag does URL rewriting, but **not** URL encoding!

```jsp
<set var="last" value="Hidden Cursor" />
<set var="first" value="Crouching Pixels"/>

<c:url value="/inputComments.jsp?first=${first}&last=${last}" var="inputURL" />
The URL using params is: ${inputURL} <br/>
```

Use the optional “var” attribute when you want access to this value later.

```
Vain! Query string parameters have to be encoded... spaces, for example, must be replaced with a plus “+” sign.
```

Using `<c:param>` in the body of `<curl>`

This solves our problem! Now we get both URL rewriting and URL encoding.

```jsp
<c:url value="/inputComments.jsp" var="inputURL" />
<c:param name="firstName" value="${first}" />
<c:param name="lastName" value="${last}" />
</curl>
```

Now the URL looks like this:

```
/myApp/inputComments.jsp?firstName=Crouching+Pixels&lastName=Hidden+Cursor
```

456  
chapter 9
Chapter 9. Custom tags are powerful

I’m interrupting this JSTL talk for a few moments to talk about your error-handling. We’re about to do something that might cause an exception.

You do NOT want your clients to see this:

```
HTTP Status 500 -

Problem description

The given request resulted in an internal error that occurred after fulfilling the request.

Exception

java.lang.ArithmeticException: / by zero

you are here → 457
```
**error pages**

**Make your own error pages**

The guy surfing your site doesn’t want to see your stack trace. And he’s not too thrilled to get a standard “404 Not Found”, either.

You can’t prevent all errors, of course, but you can at least give the user a friendlier (and more attractive) error response page. You can design a custom page to handle errors, then use the page directive to configure it.

**The designated ERROR page (“errorPage.jsp”)**

```
<%@ page isErrorPage="true" %>
<html><body>
  <strong>Bummer.</strong>
</body></html>
```

**The BAD page that throws an exception (“badPage.jsp”)**

```
<%@ page errorPage="errorPage.jsp" %>
<html><body>
  About to be bad...
  <% int x = 10/0 %>
</body></html>
```

**What happens when you request “badPage.jsp”**

The REQUEST was for “badPage.jsp”, but that page threw an exception, so the RESPONSE came from “errorPage.jsp”.

---

Chapter 9. Custom tags are powerful

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham

Chapter 9. Custom tags are powerful

She doesn't know about the `<error-page>` DD tag.

You can declare error pages in the DD for the entire web app, and you can even configure different error pages for different exception types, or HTTP error code types (404, 500, etc.).

The Container uses `<error-page>` configuration in the DD as the default, but if a JSP has an explicit `errorPage` page directive, the Container uses the directive.

**using JSTL**

It will take me FOREVER to put page directives in all my JSPs, to specify the error page to use. And what if I want a different error page depending on the error? If only there were a way to configure error pages for the whole web app...
Configuring error pages in the DD

You can declare error pages in the DD based on either the <exception-type> or the HTTP status <error-code> number. That way you can show the client different error pages specific to the type of the problem that generated the error.

Declaring a catch-all error page

This applies to everything in your web app—not just JSPs. You can override it in individual JSPs by adding a page directive with an errorPage attribute.

```xml
<error-page>
  <exception-type>java.lang.Throwable</exception-type>
  <location>/errorPage.jsp</location>
</error-page>
```

Declaring an error page for a more explicit exception

This configures an error page that’s called only when there’s an ArithmeticException. If you have both this declaration and the catch-all above, any exception other than ArithmeticException will still end up at the “errorPage.jsp”.

```xml
<error-page>
  <exception-type>java.lang.ArithmeticException</exception-type>
  <location>/arithmeticError.jsp</location>
</error-page>
```

Declaring an error page based on an HTTP status code

This configures an error page that’s called only when the status code for the response is “404” (file not found).

```xml
<error-page>
  <exception-type>java.lang.Throwable</exception-type>
  <location>/notFoundError.jsp</location>
</error-page>
```

The <location> MUST be relative to the web-app root/context, which means it MUST start with a slash. (This is true regardless of whether the error page is based on <error-code> or <exception-type>).
Error pages get an extra object: exception

An error page is essentially the JSP that handles the exception, so the Container gives the page an extra object for the exception. You probably won’t want to show the exception to the user, but you’ve got it. In a scriptlet, you can use the implicit object exception, and from a JSP you can use the EL implicit object ${pageContext.exception}. The object is type java.lang.Throwable, so in a script you can call methods, and with EL you can access the stackTrace and message properties.

A more explicit ERROR page (“errorPage.jsp”)

```jsp
<%@ page isErrorPage="true" %>

<html><body>
<stron>Bummer.</stron><br>
You caused a ${pageContext.exception} on the server.<br>
<img src="images/bummerGuy.jpg">
</body></html>
```

What happens when you request “badPage.jsp”

This time, you get more details. You probably won’t show this to the user, you just did this so you could see it.
the `<c:catch>` tag

What if I think there’s an exception I might be able to recover from in a JSP? What if there are some errors I want to catch myself?

The `<c:catch>` tag. Like try/catch...sort of

If you have a page that invokes a risky tag, but you think you can recover, there’s a solution. You can do a kind of try/catch using the `<c:catch>` tag, to wrap the risky tag or expression. Because if you don’t, and an exception is thrown, your default error handling will kick in and the user will get the error page declared in the DD. The part that might feel a little strange is that the `<c:catch>` serves as both the try and the catch—there’s no separate `try` tag. You wrap the risky EL or tag calls or whatever in the body of a `<c:catch>`, and the exception is caught right there. But you can’t assume it’s exactly like a catch block, either, because once the exception occurs, control jumps to the end of the `<c:catch>` tag body (more on that in a minute).

```jsp
taglib prefix="c" uri="http://java.sun.com/jsp/jstl/core" />
tag page errorPage="errorPage.jsp" />
<html>body
	About to do a risky thing: <br>
	<c:catch>
		<%! int x = 10/0; %>
	</c:catch>
If you see this, we survived.
</body></html>
```

This scriptlet will DEFINITELY cause an exception... but we caught it instead of triggering the error page.

If this prints out, then we KNOW we made it past the exception (which in this example, means we successfully caught the exception).

About to do a risky thing:
If you see this, we survived.

the catch must have worked...
You can make the exception an attribute

In a real Java try/catch, the catch argument is the exception object. But with web app error handling, remember, only officially-designated error pages get the exception object. To any other page, the exception just isn’t there. So this does not work:

```jsp
<br>
<c:catch>
  <%! int x = 10/0; %>
</c:catch>
<br>
Exception was: ${pageContext.exception}
```

Using the "var" attribute in `<c:catch>`

Use the optional var attribute if you want to access the exception after the end of the `<c:catch>` tag. It puts the exception object into the page scope, under the name you declare as the value of var.

```jsp
<br>
<c:catch var="myException">
  Inside the catch...
  <%! int x = 10/0; %>
</c:catch>
<br>
<%if test="$\{myException\} != null"%>
  We survived.
</%if>
```

This creates a new page-scoped attribute named "myException", and assigns the exception object to it. Now there’s an attribute myException, and since it’s a Throwable, it has a message property (because Throwable has a getMessage() method).
the `<c:catch>` tag

Flow control works in a `<c:catch>` the way it does in a try block—NOTHING runs inside the `<c:catch>` body after the exception.

In a regular Java try/catch, once the exception occurs, the code below that point in the try block never executes—control jumps directly to the catch block. With the `<c:catch>` tag, once the exception occurs, two things happen:

1) If you used the optional "var" attribute, the exception object is assigned to it.

2) Flow jumps to below the body of the `<c:catch>` tag.

```xml
<c:catch>
  <c:choose>
    <c:when test=" ${x == 0} ">
      control
    </c:when>
    <c:otherwise>
      After the catch...
    </c:otherwise>
  </c:choose>
</c:catch>
```

Inside the catch...

```java
int x = 10/0; %
```

You'll NEVER see this!

We survived.

Be careful about this. If you want to use the "var" exception object, you must wait until AFTER you get to the end of the `<c:catch>` body. In other words, there is simply no way to use any information about the exception WITHIN the `<c:catch>` tag body.

It's tempting to think of a `<c:catch>` tag as being just like a normal Java code catch block, but it isn't. A `<c:catch>` acts more like a try block, because it's where you put the risky code. Except it's like a try that never needs (or has) a catch or finally block. Confused? The point is—learn this tag for exactly what it is, rather than mapping it into your existing knowledge of how a normal try/catch works. And on the exam, if you see code within the `<c:catch>` tag that is below the point at which the exception is thrown, don't be fooled.
What if you need a tag that’s NOT in JSTL?

The JSTL is huge. Version 1.1 has five libraries—four with custom tags, and one with a bunch of functions for String manipulation. The tags we cover in this book (which happen to be the ones you’re expected to know for the exam) are for the generic things you’re most likely to need, but it’s possible that between all five libraries, you’ll find everything you might ever need. On the next page, we’ll start looking at what happens when the tags below aren’t enough.

<table>
<thead>
<tr>
<th>The “Core” library</th>
<th>The “Formatting” library</th>
<th>The “XML” library</th>
</tr>
</thead>
<tbody>
<tr>
<td>General purpose</td>
<td>Internationalization</td>
<td>Core XML actions</td>
</tr>
<tr>
<td>&lt;c:out&gt;</td>
<td><a href="">fmt:message</a></td>
<td>&lt;x:parse&gt;</td>
</tr>
<tr>
<td>&lt;c:set&gt;</td>
<td><a href="">fmt:setLocale</a></td>
<td>&lt;x:out&gt;</td>
</tr>
<tr>
<td>&lt;c:remove&gt;</td>
<td><a href="">fmt:bundle</a></td>
<td>&lt;x:set&gt;</td>
</tr>
<tr>
<td>&lt;c:catch&gt;</td>
<td><a href="">fmt:setBundle</a></td>
<td>XML flow control</td>
</tr>
<tr>
<td>Conditional</td>
<td><a href="">fmt:param</a></td>
<td>&lt;x:if&gt;</td>
</tr>
<tr>
<td>&lt;c:if&gt;</td>
<td><a href="">fmt:requestEncoding</a></td>
<td>&lt;x:choose&gt;</td>
</tr>
<tr>
<td>&lt;c:choose&gt;</td>
<td>Formatting</td>
<td>&lt;x:when&gt;</td>
</tr>
<tr>
<td>&lt;c:when&gt;</td>
<td><a href="">fmt:timeZone</a></td>
<td>&lt;x:otherwise&gt;</td>
</tr>
<tr>
<td>&lt;c:otherwise&gt;</td>
<td><a href="">fmt:setTimeZone</a></td>
<td>&lt;x:forEach&gt;</td>
</tr>
<tr>
<td>URL related</td>
<td><a href="">fmt:formatNumber</a></td>
<td>Transform actions</td>
</tr>
<tr>
<td>&lt;c:import&gt;</td>
<td><a href="">fmt:parseNumber</a></td>
<td>&lt;x:transform&gt;</td>
</tr>
<tr>
<td>&lt;c:url&gt;</td>
<td><a href="">fmt:parseDate</a></td>
<td>&lt;x:param&gt;</td>
</tr>
<tr>
<td>&lt;c:redirect&gt;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>&lt;c:param&gt;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Iteration</td>
<td></td>
<td></td>
</tr>
<tr>
<td>&lt;c:forEach&gt;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>&lt;c:forEachToken&gt;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

We didn’t cover this one... it lets you iterate over tokens where you give it the delimiter. Works a lot like StringTokenizer. We also didn’t cover <c:redirect> and <c:out>, but that gives you a wonderful excuse to get the JSTL docs.

The “XML” library

Core XML actions

<xml:parse>  
<xml:out>  
<xml:set>  
XML flow control

<x:if>  
<x:choose>  
<x:when>  
<x:otherwise>  
<x:forEach>  
Transform actions

<x:transform>  
<x:param>  

Only the “core” library is covered on the exam.

The “core” library (which by convention we always prefix with “<x:”) is the only JSTL library covered on the exam. The rest are specialized, so we don’t go into them. But you should at least know that they’re available. The XML transformation tags, for example, could save your life if you need to process XML documents. Writing your own custom tags can be a pain, so make sure before you write one that you’re not reinventing the wheel.

using JSTL
Chapter 9. Custom tags are powerful

Creating the code that goes behind a tag (in other words, the Java code that’s invoked when you put the tag in your JSP) isn’t trivial. We have a whole chapter (the next one) devoted to developing your own custom tag handlers. But the last part of this chapter is about how to use custom tags. What happens, for example, if someone hands you a custom tag library they created for your company or project? How do you know what the tags are and how to use them? With JSTL, it’s easy—the JSTL 1.1 specification documents each tag, including how to use each of the required and optional attributes.

But not every custom tag will come so nicely packaged and well-documented. You have to know how to figure out a tag even if the documentation is weak or nonexistent, and, one more thing—you have to know how to deploy a custom tag library.

Main things you have to know:

1. **The tag name and syntax**
   The tag has a name, obviously. In `<c:if>`, the tag name is `if`, and the prefix is `c`. You can use any prefix you want, but the name comes from the TLD. The syntax includes things like required and optional attributes, whether the tag can have a body (and if so, what you can put there), the type of each attribute, and whether the attribute can be an expression (vs. a literal String).

2. **The library URI**
   The URI is a unique identifier in the Tag Library Descriptor (TLD). In other words, it’s a unique name for the tag library the TLD describes. The URI is what you put in your `<taglib>` directive. It’s what tells the Container how to identify the TLD file within the web app, which the Container needs in order to map the tag name used in the JSP to the Java code that runs when you use the tag.
Making sense of the TLD

The TLD describes two main things: custom tags and EL functions. We used one when we made the dice rolling function in the previous chapter, but we had only a <function> element in the TLD. Now we have to look at the <tag> element, which can be more complex. Besides the function we declared earlier, the DD below describes one tag, advice.

```xml
  <taglib-version>0.9</taglib-version>
  <short-name>RandomTags</short-name>
  <name>rollit</name>
  <function-class>foo.DiceRoller</function-class>
  <function-signature>int rollDice()</function-signature>
  <uri>randomThings</uri>
  <tag>
    <description>random advice</description>
    <name>advice</name>
    <tag-class>foo.AdvisorTagHandler</tag-class>
    <body-content>empty</body-content>
  </tag>
</taglib>
```

This is the version of the XML schema that you use for JSP 2.0. Don't memorize it—just copy it into your <taglib> element.

The EL function we used in the last chapter.

The unique name we use in the taglib directive!

Optional, but a really good idea...

MANDATORY; mainly for tools to use.

REQUIREd! This says that the tag must NOT have anything in the body.

REQUIREd! This says the tag has attributes, then one <attribute> element per tag attribute is required.

This says you MUST put a "user" attribute in the tag.

This says the "user" attribute can be a runtime expression value (i.e. doesn't have to be a String literal).

Chapter 9. Custom tags are powerful
Using the custom "advice" tag

The "advice" tag is a simple tag that takes one attribute—the user name—and prints out a piece of random advice. It’s simple enough that it could have been just a plain old EL function (with a static method getAdvice(String name)), but we made it a simple tag to show you how it all works...

The TLD elements for the advice tag

```
<taglib ...>
  ...
  <url>randomThings</url>
  <tag>
    <description>Random advice</description>
    <tag-class>foo.AdvisorTagHandler</tag-class>
    <body-content>empty</body-content>
    <attribute>
      <name>user</name>
      <required>true</required>
      <rexpvalue>true</rexpvalue>
    </attribute>
  </tag>
</taglib>...
```

JSP that uses the tag

```
<html>
  <body>
    {@ taglib prefix="mine" uri="randomThings"} 
    Advisor tag <br>
    <mine:advice user="${userName}" />
  </body>
</html>
```
Chapter 9. Custom tags are powerful

The custom tag handler

This simple tag handler extends SimpleTagSupport (a class you’ll see in the next chapter), and implements two key methods: doTag(), the method that does the actual work, and setUser(), the method that accepts the attribute value.

Java class that does the tag work

```java
package foo;
import javax.servlet.jsp.JspException;
import javax.servlet.jsp.tagext.SimpleTagSupport;
import java.io.IOException;

public class AdvisorTagHandler extends SimpleTagSupport {

    private String user;

    public void doTag() throws JspException, IOException {
        getJspContext().getOut().write("Hello "+ user + " <br>");
        getJspContext().getOut().write("Your advice is: "+ getAdvice());
    }

    public void setUser(String user) {
        this.user = user;
    }

    String getAdvice() {
        String[] adviceStrings = {"That color’s not working for you.",
                                  "You should call in sick.",
                                  "You might want to rethink that haircut."};
        int random = (int) (Math.random() * adviceStrings.length);
        return adviceStrings[random];
    }
}
```

Custom tag handlers don’t use custom method names!

With EL functions, you created a Java class with a static method, named the method whatever you wanted, then used the TLD to map the actual method <function-signature> to the function name. But with custom tags, the method name is ALWAYS doTag(), so you never declare the method name for a custom tag. Only functions use a method signature declaration in the TLD!
understanding <rtexprvalue>

Pay attention to <rtexprvalue>

The <rtexprvalue> is especially important because it tells you whether the value of the attribute is evaluated at translation or runtime. If the <rtexprvalue> is false, or the <rtexprvalue> isn't defined, you can use only a String literal as that attribute's value!

If you see this:

```
<attribute>
  <name>rate</name>
  <required>true</required>
  <rtexprvalue>false</rtexprvalue>
</attribute>
```

OR this:

```
<attribute>
  <name>rate</name>
  <required>true</required>
</attribute>
```

Then you know THIS WON'T WORK!

```
<html><body>
  <$taglib prefix="my" uri="myTags">$
  <my:handleIt rate="${currentRate}" />
</body></html>
```

Q: You still didn't answer the question about how you know what type the attribute is...

A: We'll start with the easy one. If the <rtexprvalue> is false (or not there at all), then the attribute type can be ONLY a String literal. But if you can use an expression, then you have to hope that it's either dead obvious from the tag description and attribute name, OR that the developer included the optional <type> subelement of the <attribute> element. The <type> takes a fully-qualified class name for the type. Whether the TLD declares the type or not, the Container expects the type of the expression to match the type of argument in the tag handler's setter method for that attribute. In other words, if the tag handler has a setDog(Dog) method for the "dog" attribute, then the value of your expression for that attribute better evaluate to a Dog object! (Or something that can be implicitly assigned to a Dog reference type.)
<rtexprvalue> is NOT just for EL expressions

You can use three kinds of expressions for the value of an attribute (or tag body) that allows runtime expressions.

1. EL expressions
   `<mine:advice user="${userName}" />

2. Scripting expressions
   `<mine:advice user="<%= request.getAttribute("username") %>" />
   It has to be an expression, not just a scriplet.
   So it must have the "=" sign in there and no semicolon on the end

3. `<jsp:attribute` standard actions
   `<mine:advice>
   `<jsp:attribute name="user">${userName}</jsp:attribute>
   `<jsp:attribute name="other">value</jsp:attribute>
   </mine:advice>

What is this?? I thought this tag didn’t have a body...

The `<jsp:attribute>` lets you put attributes in the BODY of a tag, even when the tag body is explicitly declared "empty" in the TLD!

The `<jsp:attribute>` is simply an alternate way to define attributes to a tag. The key point is, there must be only ONE `<jsp:attribute>` for EACH attribute in the enclosing tag. So if you have a tag that normally takes three attributes IN the tag (as opposed to in the body), then inside the body you’ll now have three `<jsp:attribute>` tags, one for each attribute. Also notice that the `<jsp:attribute>` has an attribute of its own, name, where you specify the name of the outer tag’s attribute for which you’re setting a value.

There’s a little more about this on the next page...
**Tag bodies**

### What can be in a tag body

A tag can have a body only if the `<body-content>` element for this tag is not configured with a value of `empty`. The `<body-content>` element can be one of either three or four values, depending on the type of tag.

- `<body-content>empty</body-content>`: The tag must NOT have a body
- `<body-content>scriptless</body-content>`: The tag must NOT have scripting elements (scriptlets, scripting expressions, and declarations), but it CAN have template text and EL and custom and standard actions.
- `<body-content>tagdependent</body-content>`: The tag body is treated as plain text, so the EL is NOT evaluated and tags/actions are not triggered
- `<body-content>JSP</body-content>`: The tag body can have anything that can go inside a JSP.

### THREE ways to invoke a tag that can't have a body

Each of these are acceptable ways to invoke a tag configured in the TLD with `<body-content>empty</body-content>`:

1. **An empty tag**
   ```xml
   <mine:advice user="${userName}" />
   ```

2. **A tag with nothing between the opening and closing tags**
   ```xml
   <mine:advice user="${userName}" />
   ```

3. **A tag with only `<jsp:attribute>` tags between the opening and closing tags**
   ```xml
   <mine:advice>
     <jsp:attribute name="user">${userName}</jsp:attribute>
   </mine:advice>
   ```

The `<jsp:attribute>` tag is the ONLY thing you can put between the opening and closing tags of a tag with a `<body-content>` of `empty`. It’s just an alternate way to put the attributes in, but `<jsp:attribute>` tags don’t count as “body content”.
The tag handler, the TLD, and the JSP

The tag handler developer creates the TLD to tell both the Container and the JSP developer how to use the tag. A JSP developer doesn’t care about the `<tag-class>` element in the TLD; that’s for the Container to worry about. The JSP developer cares most about the uri, the tag name, and the tag syntax. Can the tag have a body? Does this attribute have to be a String literal, or can it be an expression? Is this attribute optional? What type does the expression need to evaluate to?

Think of the TLD as the API for custom tags. You have to know how to call it and what arguments it needs.
The taglib <uri>

The <uri> element in the TLD is a unique name for the tag library. That’s it. It does NOT need to represent any actual location (path or URL, for example). It simply has to be a name—the same name you use in the taglib directive.

“But,” you’re asking, “how come with the JSTL it gives the full URL to the library?” The taglib directive for the JSTL is:

```xml
<%@ taglib prefix="c" uri="http://java.sun.com/jsp/jstl/core" %>
```

The web Container doesn’t normally try to request something from the uri in the taglib directive. It doesn’t need to use the uri as a location! If you type that as a URL into your browser, you’ll be redirected to a different URL, one that has information about JSTL. The Container could care less that this particular uri happens to also be a valid URL (the whole “http://...” thing). It’s just the convention Sun uses for the uri, to help ensure that it’s a unique name. Sun could have named the JSTL uri “java.foo_tags” and it would have worked in exactly the same way. All that matters is that the <uri> in the TLD and the uri in the taglib directive match.

As a developer, though, you do want to work out a scheme to give your libraries unique <uri> names, because <uri> names need to be unique for any given web app. You can’t, for example, have two TLD files in the same web app, with the same <uri>. So, the domain name convention is a good one, but you don’t necessarily need to use that for all of your in-house development.

Having said all that, there is one way in which the uri could be used as a location, but it’s considered a really bad practice—if you don’t specify a <uri> inside the TLD, the Container will attempt to use the uri attribute in the taglib directive as a path to the actual TLD. But to hard-code the location of your TLD is obviously a bad idea, so just pretend you don’t know it’s possible.

The Container looks for a match between the <uri> in the TLD and the uri value in the taglib directive. The uri does NOT have to be the location of the actual tag handler!
### The Container builds a map

Before JSP 2.0, the developer had to specify a mapping between the `<uri>` in the TLD and the actual location of the TLD file. So when a JSP page had a `<taglib>` directive like this:

```xml
<taglib prefix="mine" uri="randomThings"/>
```

The Deployment Descriptor (web.xml) had to tell the Container where the TLD file with a matching `<uri>` was located. You did that with a `<taglib>` element in the DD.

### The OLD (before JSP 2.0) way to map a taglib uri to a TLD file

```xml
<web-app>
  ...
  <jsp-config>
    <taglib>
      <taglib-uri>randomThings</taglib-uri>
      <taglib-location>/WEB-INF/myFunctions.tld</taglib-location>
    </taglib>
  </jsp-config>
</web-app>
```

### The NEW (JSP 2.0) way to map a taglib uri to a TLD file

No `<taglib>` entry in the DD!

The Container automatically builds a map between TLD files and `<uri>` names, so that when a JSP invokes a tag, the Container knows exactly where to find the TLD that describes the tag.

How? By looking through a specific set of locations where TLDs are allowed to live. When you deploy a web app, as long as you put the TLD in a place the Container will search, the Container will find the TLD and build a map for that tag library.

If you do specify an explicit `<taglib-location>` in the DD (web.xml), a JSP 2.0 Container will use it! In fact, when the Container begins to build the `<uri>`-to-TLD map, the Container will look first in your DD to see if you’ve made any `<taglib>` entries, and if you have, it’ll use those to help construct the map. For the exam, you’re expected to know about `<taglib-location>`, even though it’s no longer required for JSP 2.0.

So the next step is for us to see where the Container looks for TLDs, and also where it looks for the tag handler `class` declared in the TLDs.

---

**using JSTL**

In the DD, map the `<uri>` in the TLD to an actual path to a TLD file.

**TLD locations**

**Four places the Container looks for TLDs**

The Container searches in several places to find TLD files—you don’t need to do anything except make sure your TLDs are in one of the right locations.

1. Directly inside WEB-INF
2. Directly inside a sub-directory of WEB-INF
3. Inside the META-INF directory inside a JAR file that's inside WEB-INF/lib
4. Inside a sub-directory of META-INF inside a JAR file that's inside WEB-INF/lib
When a JSP uses more than one tag library

If you want to use more than one tag library in a JSP, do a separate taglib directive for each TLD. There are a few issues to keep in mind...

- Make sure the taglib uri names are unique. In other words, don’t put in more than one directive with the same uri value.

- Do NOT use a prefix that’s on the reserved list. The reserved prefixes are:
  - jsp:
  - jspx:
  - java:
  - javax:
  - servlet:
  - sun:
  - sunw:

Empty tags

Write in examples of the THREE different ways to invoke a tag that must have an empty body. (Check your answers by looking back through the chapter. No, we’re not going to tell you the page number.)

1. 

2. 

3.
### TLD exercise

#### Sharpen your pencil

**How the JSP, the TLD, and the bean attribute class relate**

Fill in the spaces based on the information that you can see in the TLD. Draw arrows to indicate where the different pieces of information are tied together. In other words, for each blank, show exactly where you found the information needed to fill in the blank.

**JSP that uses the tag**

```html
<body>
  <jsp:useBean id="foo" class="com.my.package.MyBean"/>
  <jsp:getProperty name="foo" property="property1"/>
</body>
```

**TLD file**

```xml
<taglib ...>
  ...<uri>randomThings</uri>
  <tag>
    <description>Random advice</description>
    <name>advice</name>
    <tag-class>com.my.package.MyBean</tag-class>
    <attribute>
      <name>user</name>
      <required>true</required>
      <rtexprvalue>${user}</rtexprvalue>
    </attribute>
  </tag>
</taglib>
```

**AdvisorTagHandler class**

```java
public class AdvisorTagHandler extends TagSupport {
  @Override
  public int doStartTag() throws JspTagException {
    throw new JspTagException("This handle does not support start tag.");
  }

  @Override
  public int doEndTag() throws JspTagException {
    throw new JspTagException("This handle does not support end tag.");
  }

  @Override
  public void setAttribute(String name, Object attribute) throws JspTagException {
    throw new JspTagException("This handle does not support attributes.");
  }
}
```
Chapter 9. Custom tags are powerful

using JSTL

Test your Tag memory
ANSWERS

1. Fill in the name of the optional attribute.

   ```xml
   <c:forEach var="movie" items="${movieList}" varStatus="foo">
     $movie
   </c:forEach>
   ```

2. Fill in the missing attribute name.

   ```xml
   <c:if test="${userPref=="safety"}">
     Maybe you should just walk...
   </c:if>
   ```

3. Fill in the missing attribute name.

   ```xml
   <c:set var="userLevel" scope="session" value="foo" />
   ```

4. Fill in the missing tag names (two different tag types), and the missing attribute name.

   ```xml
   <c:choose>
     <c:when test="${userPref == 'performance'}">
       Now you can stop even if you <em>do</em> drive insanely fast.
     </c:when>
     <c:otherwise>
       Our brakes are the best.
     </c:otherwise>
   </c:choose>
   ```

   The `<c:otherwise>` tag is optional.
TLD exercise answers

Sharpen your pencil

How the JSP, the TLD, and the bean attribute class relate
ANSWERS

JSP that uses the tag
```html
<html>
<body>
<%@ taglib prefix="mine" uri="randomThings"%>
<mine:advise user="\$(userName)"/>
</body>
</html>
```

TLD file
```xml
<taglib ...>
<url>randomThings</url>
<tag>
<description>random advice</description>
<name>advise</name>
<tag-class>foo.AdvisorTagHandler</tag-class>
<body-content-wraps>$</body-content-wraps>
<attribute>
<name>user</name>
<required>true</required>
<rtexprvalue>true</rtexprvalue>
</attribute>
</tag>
```

AdvisorTagHandler class
```java
void doTag() {
// tag logic
}
void set(user(String user) {
this.user=user;
```

Chapter 9. Custom tags are powerful
1 Which is true about TLD files?
   - A. TLD files may be placed in any subdirectory of WEB-INF.
   - B. TLD files are used to configure JSP environment attributes, such as scripting-invalid.
   - C. TLD files may be placed in the META-INF directory of the WAR file.
   - D. TLD files can declare both Simple and Classic tags, but TLD files are NOT used to declare Tag Files.

2 Assuming the standard JSTL prefix conventions are used, which JSTL tags would you use to iterate over a collection of objects? (Choose all that apply.)
   - A. <x:forEach>
   - B. <c:iterate>
   - C. <c:forEach>
   - D. <c:forTokens>
   - E. <logic:iterate>
   - F. <logic:forEach>
A JSP page contains a `<taglib>` directive whose `uri` attribute has the value `myTags`. Which deployment descriptor element defines the associated TLD?

A. `<taglib>`
   `<uri>myTags</uri>`
   `<location>/WEB-INF/myTags.tld</location>`
   `</taglib>`

B. `<taglib>`
   `<uri>myTags</uri>`
   `<tld-location>/WEB-INF/myTags.tld</tld-location>`
   `</taglib>`

C. `<taglib>`
   `<tld-uri>myTags</tld-uri>`
   `<tld-location>/WEB-INF/myTags.tld</tld-location>`
   `</taglib>`

D. `<taglib>`
   `<taglib-uri>myTags</taglib-uri>`
   `<taglib-location>/WEB-INF/myTags.tld</taglib-location>`
   `</taglib>`

A JavaBean `Person` has a property called `address`. The value of this property is another JavaBean `Address` with the following string properties:

- `street1`, `street2`, `city`, `stateCode` and `zipCode`. A controller servlet creates a session-scoped attribute called `customer` that is an instance of the `Person` bean.

Which JSP code structures will set the `city` property of the `customer` attribute to the `city` request parameter? (Choose all that apply.)

A. `$(sessionScope.customer.address.city = param.city)`

B. `<c:set target="$(sessionScope.customer.address)" property="city" value="${param.city}"/>

C. `<c:set scope="session" var="${param.customer}" property="city" value="${param.city}"/>

D. `<c:set target="${sessionScope.customer.address}" property="city"> ${param.city} </c:set>`
5. Which `<body-content>` element combinations in the TLD are valid for the following JSP snippet? (Choose all that apply.)

   <pre>
   &lt;my:tag1&gt;
   &lt;my:tag2 a="47" /&gt;
   &lt;% a = 420; %&gt;
   &lt;my:tag3&gt;
   value = $(a)
   &lt;/my:tag3&gt;
   &lt;/my:tag1&gt;
   </pre>

   A. tag1 body-content is empty
tag2 body-content is JSP
tag3 body-content is scriptless
   B. tag1 body-content is JSP
tag2 body-content is empty
tag3 body-content is scriptless
   C. tag1 body-content is JSP
tag2 body-content is JSP
tag3 body-content is JSP
   D. tag1 body-content is scriptless
tag2 body-content is JSP
tag3 body-content is JSP
   E. tag1 body-content is JSP
tag2 body-content is scriptless
tag3 body-content is scriptless

---

6. Assuming the appropriate `taglib` directives, which are valid examples of custom tag usage? (Choose all that apply.)

   A. `<foo:bar />`
   B. `<my:tag&gt;&lt;/my:tag&gt;`
   C. `<my:tag values="x" />`
   D. `<:out values="x" />`
   E. `<jsp:setProperty name="a" property="b" value="c" />`
**mock exam**

7. Given the following scriptlet code:

```java
<select name='styleId'>
   <BeerStyles[] styles = beerService.getStyles();
   for ( int i=0; i < styles.length; i++ ) {
      BeerStyle style = styles[i];
      <option value='<%= style.getObjectID() %>'>
         <%= style.getTitle() %>
      </option>
   }
</select>
```

Which JSTL code snippet produces the same result?

- A. `<select name='styleId'>
   <c:for array='${beerService.styles}'>
      <option value='${item.objectID}'>${item.title}</option>
   </c:for>
</select>`

- B. `<select name='styleId'>
   <c:forEach var='style' items='${beerService.styles}'>
      <option value='${style.objectID}'>${style.title}</option>
   </c:forEach>
</select>`

- C. `<select name='styleId'>
   <c:forEach var='style' array='${beerService.styles}'>
      <option value='${style.objectID}'>${style.title}</option>
   </c:forEach>
</select>`

- D. `<select name='styleId'>
   <c:forEach var='style' array='${beerService.styles}'>
      <option value='${style.objectID}'>${style.title}</option>
   </c:forEach>
</select>
1. Which is true about TLD files?

- A. TLD files may be placed in any subdirectory of WEB-INF.
- B. TLD files are used to configure JSP environment attributes, such as scripting-invalid.
- C. TLD files may be placed in the META-INF directory of the WAR file.
- D. TLD files can declare both Simple and Classic tags, but TLD files are NOT used to declare Tag Files.

2. Assuming the standard JSTL prefix conventions are used, which JSTL tags would you use to iterate over a collection of objects? (Choose all that apply.)

- A. `<x:forEach>` - Option A is incorrect as this is the tag used for iterating over XPath expressions.
- B. `<c:iterate>` - Option B is incorrect because there is no such tag.
- C. `<c:forEach>`
- D. `<c:forTokens>` - Option D is incorrect because this tag is used for iterating over tokens within a single string.
- E. `<logic:iterate>` - Options E and F are incorrect because the prefix 'logic' is not a standard JSTL prefix (this prefix is typically used by tags in the Jakarta Struts package).
- F. `<logic:forEach>`
mock answers

3. A JSP page contains a taglib directive whose uri attribute has the value myTags. Which deployment descriptor element defines the associated TLD?

- Option A: `<taglib`
  `<uri>myTags</uri>`
  `<location>/WEB-INF/myTags.tld</location>`
  `</taglib>`

- Option B: `<taglib`
  `<uri>myTags</uri>`
  `<tld-location>/WEB-INF/myTags.tld</tld-location>`
  `</taglib>`

- Option C: `<taglib`
  `<tld-uri>myTags</tld-uri>`
  `<tld-location>/WEB-INF/myTags.tld</tld-location>`
  `</taglib>`

- Option D: `<taglib-uri>myTags</taglib-uri>`
  `<taglib-location>/WEB-INF/myTags.tld</taglib-location>`
  `</taglib>`

4. A JavaBean Person has a property called address. The value of this property is another JavaBean Address with the following string properties: street1, street2, city, stateCode and zipCode. A controller servlet creates a session-scoped attribute called customer that is an instance of the Person bean.

Which JSP code structures will set the city property of the customer attribute to the city request parameter? (Choose all that apply)

- Option A is invalid because EL does not permit assignment.

- Option C is invalid because the var attribute does not accept a runtime value, nor does it work with the property attribute.
using JSTL

Which `<body-content>` element combinations in the TLD
are valid for the following JSP snippet? (Choose all that apply.)

```html
<my:tag>
  <% a = 420; %>
</my:tag>
```

A. tag1 body-content is `empty`
   tag2 body-content is `JSP`
   tag3 body-content is `scriptless`

B. tag1 body-content is `JSP`
   tag2 body-content is `empty`
   tag3 body-content is `scriptless`

C. tag1 body-content is `JSP`
   tag2 body-content is `JSP`
   tag3 body-content is `scriptless`

D. tag1 body-content is `scriptless`
   tag2 body-content is `JSP`
   tag3 body-content is `JSP`

E. tag1 body-content is `JSP`
   tag2 body-content is `scriptless`
   tag3 body-content is `scriptless`

Assuming the appropriate `taglib` directives, which are valid
examples of custom tag usage? (Choose all that apply.)

```html
A. <foo:bar />
B. <my:tag/></my:tag>
D. <c:out value="a"/>
E. <jsp:setProperty name="a" property="b" value="c"/>
```

- Option A is invalid because tag1 cannot be `empty`.
- Option C is invalid because there is no prefix.
- Option E is invalid because this is an example of a JSP standard action, not a custom tag.

---

(JSTL v1.1 pg 6-48)
When even JSTL is not enough...

Sometimes JSTL and standard actions aren’t enough.

When you need something custom, and you don’t want to go back to scripting, you can write your own tag handlers. That way, your page designers can use your tag in their pages, while all the hard work is done behind the scenes in your tag handler class. But there are three different ways to build your own tag handlers, so there’s a lot to learn. Of the three, two were introduced with JSP 2.0 to make your life easier (Simple Tags and Tag Files). But you still have to learn about Classic tags for that ridiculously rare occasion when neither of the other two will do what you want. Custom tag development gives you virtually unlimited power, if you can learn to wield it...
Building a Custom Tag Library

10.1 Describe the semantics of the "Classic" custom tag event model when each event method (doStartTag(), doAfterBody(), and doEndTag()) is executed, and explain what the return value for each event method means; and write a tag handler class.

10.2 Using the PageContext API, write tag handler code to access the JSP implicit variables and access web application attributes.

10.3 Given a scenario, write tag handler code to access the parent tag and an arbitrary tag ancestor.

10.4 Describe the semantics of the "Simple" custom tag event model when the event method (doTag()) is executed; write a tag handler class; and explain the constraints on the JSP content within the tag.

10.5 Describe the semantics of the Tag File model; describe the web application structure for tag files; write a tag file; and explain the constraints on the JSP content in the body of the tag.

Coverage Notes:

Although objective 10.1 doesn’t explicitly mention the lifecycle methods associated with BodyTag (doInitBody() and setBodyContext()), you can expect to see them on the exam.

Everything you need to know related to Classic tags is covered in this chapter, including things you might not infer from objective 10.1.

Objective 10.2 (PageContext API) is covered only very briefly in this chapter, because most of what you need to know about the PageContext API has already been covered earlier in the book.

Virtually all of this objective is about using PageContext to access implicit variables and scoped attributes, both covered in the "Scriptless JSP" chapter, although we do provide a one-page summary again in this chapter.
Includes and imports can be messy

Using `<jsp:include>` or `<import>` lets you add reusable chunks of content, dynamically, to your pages. And you can even customize how the included file behaves by setting new request parameters that the included file can use.

Sure, it works fine. But should you really have to create new request parameters just to give the included file some customizing information?

Aren’t request parameters supposed to represent form data sent from the client as part of the request? While there might be good reasons to add or change request parameters in your app, using them to send something to the included file isn’t the cleanest approach.

Until JSP 2.0, there wasn’t a standard way to deploy included files—you could put the included pieces just about anywhere in the web app. And a JSP with a bunch of `<jsp:include>` or `<import>` tags isn’t the easiest thing to read. Wouldn’t it be better if the tag itself told you something about the thing being included? Wouldn’t it be nice to say something like:

```xml
<xl:logoHeader> or <xl:navBar>
```

You know where this is going...
Tag Files

Tag Files: like include, only better

With Tag Files, you can invoke reusable content using a custom tag instead of the generic <jsp:include> or <c:import>. You can think of Tag Files as a kind of “tag handler lite”, because they let page developers create custom tags, without having to write a complicated Java tag handler class, but Tag Files are really just glorified includes.

Simplest way to make and use a Tag File

1. Take an included file (like “Header.jsp”) and rename it with a .tag extension.

   ```html
   <img src="images/Web-Services.jpg" />
   ```

   This is the entire file... remember, we stripped out the opening and closing `<html>` and `<body>` tags, so they won’t be duplicated in the final JSP.

2. Put the tag file (“Header.tag”) in a directory named “tags” inside the “WEB-INF” directory.

3. Put a taglib directive (with a tagdir attribute) in the JSP, and invoke the tag.

   ```html
   <html>
   <body>
   <![CDATA[
   <%@ taglib prefix="myTags" tagdir="/WEB-INF/tags" %>
   ]]>
   <myTags:Header/>
   </body>
   </html>
   ```

   The name of the tag is simply the name of the tag file (minus the .tag extension)

   Welcome to our site.

   So instead of:

   ```html
   <jsp:include page="Header.jsp"/>
   ```

   we now have:

   ```html
   <myTags:Header/>
   ```
But how do you send it parameters?

When we included a file using `<jsp:include>`, we used the `<jsp:param>` tag inside the `<jsp:include>` to pass information to the included file. To refresh your memory on how it works with `<jsp:include>`:

### The old way: An included file that uses a param (coming from a `<jsp:param>` in the calling JSP)

```html
<img src="images/Web-Services.jpg" />
<em>strong>${param.subTitle}</strong></em>
```

### The old way: The JSP with the `<jsp:include>` and `<jsp:param>`

```html
<html><body>

<jsp:include page="Header.jsp">
  
  <jsp:param name="subTitle" value="We take the sting out of SOAP." />

</jsp:include>

<br>

Contact us at: ${initParam.mainEmail}
</body></html>
```

### The result

We take the sting out of SOAP. 

Contact us at: likewecare@wickedlysmart.com

This is from the included file.

This subtitle was passed in by the calling JSP.

This is in the calling JSP.
Tag File attributes

To a Tag File, you don’t send request parameters, you send tag attributes!

You invoke a Tag File with a tag, and tags can have attributes. So it’s only natural that the Tag File developer might want to invoke the tag with attributes... attributes that get sent to the Tag File.

Invoking the tag from the JSP

Before (using `<jsp:param>` to set a request parameter)

```html
<jsp:include page=”Header.jsp”>
    <jsp:param name=”subTitle” value=”We take the sting out of SOAP.” />
</jsp:include>
```

After (using a Tag with an attribute)

```html
<myTags:Header subTitle=”We take the String out of SOAP” />
```

Using the attribute in the Tag File

Before (using a request param value)

```html
<en><strong>${param.subTitle}</strong></en>
```

After (using a Tag File attribute)

```html
<en><strong>${subTitle}</strong></en>
```

All tag attributes have TAG scope. That’s right, just the tag. Once the tag is closed, the tag attributes go out of scope!

You have to be clear about these—the `<jsp:include>` `<jsp:param>` value goes in as a request parameter. That’s not the same as a request-scoped attribute. Remember, the name/value pair for the `<jsp:param>` looks to the web-app as though it came in with a form submission. That’s one of the reasons we DON’T like using it—the value you meant to pass ONLY to the included file, ends up visible to any component in the web app that is a part of this request (such as servlets or JSPs to which the request is forwarded). But the nice, clean thing about tag attributes for Tag Files is that they’re scoped to the tag itself. Just be sure you know the implications. This will NOT work:

```html
<%@ taglib prefix=”myTags” tagdir=”WEB-INF/tags” %>
<html><body>
<myTags:Header subTitle=”We take the String out of SOAP” />
<br />
${subTitle}
</body></html>
```

This won’t work! The attribute is out of scope.

494

chapter 10
 Aren’t tag attributes declared in the TLD?

With custom tags, including the JSTL, the tag attributes are defined in the TLD. Remember? This is the TLD from the custom `<my:advice>` tag from the last chapter:

```xml
<tag>
  <description>random advice</description>
  <name>advice</name>
  <tag-class>foo.AdvisorTagHandler</tag-class>
  <body-content>empty</body-content>
  <attribute>
    <name>user</name>
    <required>true</required>
    <rtexprvalue>true</rtexprvalue>
  </attribute>
</tag>
```

So, these are the things the developer who is using a tag needs to know: What’s the attribute name? Is it optional or required? Can it be an expression, or must it be only a String literal?

But while you do specify custom tag attributes in a TLD, you do NOT specify tag file attributes in a TLD!

That means we still have a problem—how does the page developer know what attributes the tag accepts and/or requires? Turn the page...
**attribute directive**

**Tag Files use the attribute directive**

There’s a shiny new type of directive, and it’s just for Tag Files. Nothing else can use it. It’s just like the `<attribute>` sub-element in the `<tag>` section of the TLD for a custom tag.

**Inside the Tag File**

(Header.tag)

```xml
<%@ attribute name="subTitle" required="true" rtexprvalue="true" %>
```

**Inside the JSP that uses the tag**

```jsp
<%@ taglib prefix="myTags" tagdir="/WEB-INF/tags" %>

<myTags:Header subTitle="We take the String out of SOAP" />
```

**What happens if you do NOT have the attribute when you use the tag**

```jsp
<myTags:Header />
```

It can be a String literal or an expression.

This means the attribute is not optional.

You can’t do this... you can’t leave out the subTitle attribute because the tag file’s attribute directive says `required="true`.
When an attribute value is really big

Imagine you have a tag attribute that might be as long as, say, a paragraph. Sticking that in the opening tag could get ugly. So, you can choose to put content in the body of the tag, and then use that as a kind of attribute.

This time we’ll take the subTitle attribute out of the tag, and instead make it the body of the <myTags:Header> tag.

Inside the Tag File
(Header.tag)

```
<taglib prefix="myTags" tagdir="/WEB-INF/tags" />
<html>

<myTags:Header>
  We no longer need the attribute directive.
  This says, “Take whatever is in the body of the tag used to invoke this tag file, and stick it here.”
</myTags:Header>

```

Inside the JSP that uses the tag

```
<% taglib prefix="myTags" tagdir="/WEB-INF/tags" %>
<html>

<myTags:Header>
  We take the sting out of SOAP. OK, so it’s not Jini,<br>
  but we’ll help you get through it with the least<br>
  frustration and hair loss.
</myTags:Header>

This says, “Take whatever is in the body of the tag used to invoke this tag file, and stick it here.”

<br>
Contact us at: ${initParam mainEmail}
</body></html>

But we’re back to the same problem we had before—without a TLD, where do you declare the body-content type?
**Declarating body-content for a Tag File**

The only way to declare body-content type for a Tag File is with another new Tag File directive, the *tag directive*. The tag directive is the Tag File equivalent of the *page* directive in a JSP page, and it has a lot of the same attributes plus an important one you won’t find in *page* directive—*body-content*.

For a custom tag, the `<body-content>` element inside the `<tag>` element of a TLD is mandatory! But a Tag File does not have to declare `<body-content>` if the default—*scriptless*—is acceptable. A value of *scriptless* means you can’t have scripting elements. And scripting elements, remember, are scriptlets (<% ... %>), scriptlet expressions (<%= ... %>), and declarations (<%! ... %>).

In fact, *Tag File bodies are never allowed to have scripting*, so it’s not an option. But you can declare body-content (using the tag directive with a body-content attribute) if you want one of the other two options, empty or tagdependent.

**Inside the Tag File with a *tag directive***

(Header.tag)

```xml
<%@ attribute name="fontColor" required="true" %>
<% tag body-content="tagdependent" %>

<img src="images/Web-Services.jpg" />
<br/>
<br/>
<br/>
<br/>

<% myTags:Header fontColor="#660099">
We take the sting out of SOAP. OK, so it's not Jini,<br>
but we’ll help you get through it with the least<br>
frustration and hair loss.
</myTags:Header>
<br/>
Contact us at: ${initParam.mainEmail}
</body>
</html>
```

**Inside the JSP that uses the tag**

```jsp
taglib prefix="myTags" tagdir="/WEB-INF/tags" %>
<html>

<% myTags:Header %>
```

---

The type for this body-content is declared in the Tag File using a *tag directive* with a *body-content* attribute.
Where the Container looks for Tag Files

The Container searches for tag files in four locations. A tag file MUST have a TLD if it’s deployed in a JAR, but if it’s put directly into the web app (in “WEB-INF/tags” or a sub-directory), it does not need a TLD.

**Tag File locations**

1. Directly inside WEB-INF/tags
2. Inside a sub-directory of WEB-INF/tags
3. Inside the META-INF/tags directory inside a JAR file that's inside WEB-INF/lib
4. Inside a sub-directory of META-INF/tags inside a JAR file that's inside WEB-INF/lib
5. If the tag file is deployed in a JAR, there MUST be a TLD for the tag file.
**Tag File Questions**

**Q:** Does the Tag File have access to the request and response implicit objects?

**A:** Yes! Remember, even though it's a .tag file, it's gonna end up as part of a JSP. You can use the implicit request and response objects (if you do scripting... the normal EL implicit objects are always there as well), and you have access to a JspContext as well. You don't have a ServletContext, though—a Tag File uses a JspContext instead of a ServletContext.

**Q:** I thought on the opposite page you just said we could not do scripting in a Tag File!

**A:** No, that's not exactly what we said. You can do scripting in a Tag File, but you can't do scripting inside the body of the tag used to invoke the Tag File.

**Q:** Can you combine Tag Files and TLDs for custom tags in the same directory?

**A:** Yes. In fact, if you make a TLD that references your Tag Files, the Container will consider both Tag Files and custom tags mentioned in the same TLD as belonging to the same library.

**Q:** Hold on—I thought you said Tag Files didn't have a TLD! Isn't that why you have to use an attribute directive? Since you can't declare the attribute in a TLD?

**A:** Trick question. If you deploy your Tag Files in a JAR, they MUST have a TLD that describes their location. But it doesn't describe attribute, body-content, etc. The TLD entries for a Tag File describe only the location of the actual Tag File. The TLD for a Tag File looks like this:

```xml
<taglib ...
<tag-file
      <name>/Header</name>
      <path>/META-INF/tags/Header.tag</path>
</tag-file>
</taglib>
```

Notice that declaring a `<tag-file>` is quite different from declaring an actual `<tag>`.

**Q:** Why did they do it this way? Wouldn't it be so much simpler to just have custom tags and Tag Files declared the same way in a TLD? But NO... instead they had to come up with this whole other thing where you have to use new directives for defining the attributes and body-content. So, why are tags and Tag Files done differently?

**A:** On one hand, yes, it would have been simpler if custom tags and Tag Files were declared in the same way, using a TLD. The question is, simpler for whom? For a custom tag developer, sure. But Tag Files were added to the spec with someone else in mind—page designers. Tag Files give non-Java developers a way to build custom tags without writing a Java class to handle the tag's functionality. And not having to build a TLD for the Tag File just makes life easier for the Tag File developer. (Remember, Tag Files do need a TLD if the Tag File is deployed in the JAR, but a non-Java programmer might not be using JARs anyway.)

The bottom line: custom tags must have a TLD, but Tag Files can declare attributes and body-content directly inside the Tag File, and need TLDs only if the Tag File is in a JAR.
custom tag development

Memorizing Tag Files
Before we move on to a new topic, make sure
you can write one yourself (answers are at the
eend of the chapter).

1. Fill in what would you must put into a Tag File to declare that the Tag has one required
attribute, named “title”, that can use an EL expression as the value of the attribute.

```xml
<%@ attribute name="title" expression="value" %>
```

2. Fill in what would you must put into a Tag File to declare that the Tag must NOT have a body.

```xml
<%@ bodyless %>
```

3. Draw a Tag File document
in each of the locations
where the Container will
look for Tag Files.

Chapter 10. When even JSTL is not enough...
When you need more than Tag Files... Sometimes you need Java

Tag Files are fine when you’re doing an include—when all you need to handle the tag you can do from another JSP (renamed with a .tag extension and with the appropriate directives added). But sometimes you need more. Sometimes you need good old Java code, and you don’t want to do it from scriptlets, since that’s what you’re trying to prevent by using tags.

When you need Java, you need a custom tag handler. A tag handler, as opposed to a tag file, is simply a Java class that does the work of the tag. It’s a little like an EL function, except much more powerful and flexible. Where EL functions are nothing more than static methods, a tag handler class has access to tag attributes, the tag body, and even the page context so it can get scoped attributes and the request and response.

Custom tag handlers come in two flavors: Classic and Simple. Classic tags were all you had in the previous version of JSP, but with JSP 2.0, a new and much simpler model was added. You’ll have a hard time coming up with reasons to use the classic model when you need a custom tag handler, because the simple model (especially combined with JSTL and tag files) can handle nearly anything you’d want to do. But we can’t dump the classic model for two reasons, and these two reasons are why you still have to learn it for the exam:

1) Like scripting, Classic tag handlers are out there, and you might need to read and support them, even if you never create one yourself.

2) There are those rare scenarios for which a classic tag handler is the best choice. This is pretty obscure, though. So point #1 is by far the most important reason to learn about Classic tags.
Making a Simple tag handler

For the simplest of Simple tags, the process is...simple.

1. Write a class that extends SimpleTagSupport

   ```java
   package foo;
   import javax.servlet.jsp.tagext.SimpleTagSupport;
   // more imports needed
   
   public class SimpleTagTest1 extends SimpleTagSupport {
       // tag handler code here
   }
   ```

2. Implement the doTag() method

   ```java
   public void doTag() throws JspException, IOException {
       getJspContext().getOut().print("This is the lamest use of a custom tag");
   }
   ```

3. Create a TLD for the tag

   ```xml
   <taglib ...>
   <tlib-version>1.2</tlib-version>
   <url>simpleTags</url>
   <tag>
       <description>worst use of a custom tag</description>
       <name>simple1</name>
       <tag-class>foo.SimpleTagTest1</tag-class>
       <body-content>empty</body-content>
   </tag>
   </taglib>
   ```

4. Deploy the tag handler and TLD

   Put the TLD in WEB-INF, and put the tag handler inside WEB-INF/classes, using the package directory structure, of course. In other words, tag handler classes go in the same place all other web app Java classes go.

5. Write a JSP that uses the tag

   ```jsp
   <%@ taglib prefix="myTags" uri="simpleTags" %>
   <html>
   <body>
   <myTags:SimpleTagTest1/>
   </body></html>
   ```
A Simple tag with a body

If the tag needs a body, the TLD <body-content> needs to reflect that, and you need a special statement in the doTag() method.

The JSP that uses the tag

```jsp
<%@ taglib prefix="myTags" uri="simpleTags" %>
<html><body>
Simple Tag 2:

<myTags:simple2>
  This is the body
</myTags:simple2>
</body></html>
```

The tag handler class

```java
package foo;
import javax.servlet.jsp.JspException;
import javax.servlet.jsp.tagext.SimpleTagSupport;
import java.io.IOException;

public class SimpleTagTest2 extends SimpleTagSupport {
    public void doTag() throws JspException, IOException {
        getJspBody().invoke(null);
    }
}
```

The TLD for the tag

```xml
<%@ taglib prefix="myTags" uri="simpleTags" %>
<tt xmlns="http://java.sun.com/xml/ns/j2ee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee/web-jstplibrary_2_5.xsd" version="2.0">
    <tlib-
```
The Simple tag API

A Simple tag handler must implement the SimpleTag interface. The easiest way to do that is to extend SimpleTagSupport and override just the method you need, doTag(). You don’t have to use SimpleTagSupport, but we reckon 99.999999% of simple tag developers do.

**JspTag interface**

```java
interface JspTag {
    // no methods, this interface is for organization and polymorphism
}
```

**SimpleTag interface**

```java
interface SimpleTag {
    void doTag();
    JspTag getParent();
    void setJspBody(JspFragment)
    void setJspContext(JspContext)
    void setParent(JspTag parent)
}
```

**SimpleTagSupport**

```java
class SimpleTagSupport {
    void doTag()
    JspTag findAncestorOfClass(Class JspTag, Class)
    JspFragment getJspBody()
    JspContext getJspContext()
    JspTag getParent()
    void setJspBody(JspFragment)
    void setJspContext(JspContext)
    void setParent(JspTag parent)
}
```

These are the lifecycle methods... the Container calls these whenever a tag is invoked. Can you guess the order in which these methods are called?

SimpleTagSupport implements the methods of SimpleTag (but the doTag() doesn’t do tag handling). It also adds three more useful one-getJspBody() methods...
The life of a Simple tag handler

When a JSP invokes a tag, a new instance of the tag handler class is instantiated. Two or more methods are called on the handler, and when the doTag() method completes, the handler object goes away. (In other words, these handler objects are not reused.)

A nested tag can communicate with the other tags in which it's nested!

If the tag has attributes, call attribute setters.

If the tag is NOT declared to have a body-content of empty, AND the tag has a body, call the setJspBody(JspFragment) method.

You will ALWAYS override this:

Call the doTag() method.

Now we're finally ready to do what the tag is meant to do!
custom tag development

BE the Container
Look at each of the TLD/JSP pairs. Assume that the tag handler doesn’t actually DO anything. Then answer the following questions about each one... what’s the result? If it works, what prints out? Which methods in the custom tag class are invoked?

```
<tag>
  <description/></description>
  <name>simple</name>
  <tag-class>foo.SimpleTagTest</tag-class>
  <body-content>empty</body-content>
</tag>
```

What do you see in the browser?

If it works, which SimpleTag lifecycle methods are called in the handler?

- void doTag()
- JspTag.setParent()
- void setJspBody()
- void setJspContext()
- void setParent()

```
<tag>
  <description/></description>
  <name>simple</name>
  <tag-class>foo.SimpleTagTest</tag-class>
  <body-content>scriptless</body-content>
</tag>
```

What do you see in the browser?

If it works, which SimpleTag lifecycle methods are called in the handler?

- void doTag()
- JspTag.setParent()
- void setJspBody()
- void setJspContext()
- void setParent()
Chapter 10. When even JSTL is not enough...

Simple Tag exercise answers

BE the Container Answers

<tag>
  <description></description>
  <name>simple</name>
  <tag-class>foo.SimpleTagTest</tag-class>
  <body-content>empty</body-content>
</tag>

What do you see in the browser?

It doesn't work because it is supposed to have an empty body.

If it works, which SimpleTag lifecycle methods are called in the handler?

- `void doTag()`  
- `void JspSetParent()`  
- `void setupBody()`  
- `void setupContent()`  
- `void setParent()`

<tag>
  <description></description>
  <name>simple</name>
  <tag-class>foo.SimpleTagTest</tag-class>
  <body-content>scriptless</body-content>
</tag>

What do you see in the browser?

Simple Tag: 6

If it works, which SimpleTag lifecycle methods are called in the handler?

- `void doTag()`  
- `void JspSetParent()`  
- `void setupBody()`  
- `void setupContent()`  
- `void setParent()`
**What if the tag body uses an expression?**

Imagine you have a tag with a body that uses an EL expression for an attribute. Now imagine that the attribute doesn’t exist at the time you invoke the tag. In other words, the tag body depends on the tag handler to set the attribute. The example doesn’t do anything very useful, but it’s here to show you how it works in preparation for a bigger example.

**The JSP tag invocation**

```xml
<myTags:simple3>
    Message is: $(message)
</myTags:simple3>
```

At the point where the tag is invoked, “message” is NOT a scoped attribute! If you took this expression out of the tag, it would return null.

**The tag handler doTag() method**

```java
public void doTag() throws JspException, IOException {
    getJspContext().setAttribute("message", "Near sunscreen.");
    getJspBody().invoke(null);
}
```

The tag handler sets an attribute and THEN invokes the body.

---

**Sharpen your pencil**

Imagine you have a tag that looks like this:

```xml
<table>
    <myTags:simple4>
        <tr><td>$(movie)</td></tr>
    </myTags:simple4>
</table>
```

Imagine that the tag handler has access to an array of String movie names, and you want to print one row for each movie name in the array. In the browser, you’ll see something like:

```
| Monsoon Wedding |
| Saved!          |
| Fahrenheit 9/11 |
```
**A tag with dynamic row data: iterating the body**

In this example, the EL expression in the body of the tag represents a single value in a collection, and the goal is to have the tag generate one row for each element in the collection. It’s simple—the `doTag()` method simply does the work in a loop, invoking the body on each iteration of the loop.

### The JSP tag invocation

```
<table>
  <myTags:simpleList>
    <tr><td>${movie}</td></tr>
  </myTags:simpleList>
</table>
```

The movie attribute doesn’t exist at the time the tag is invoked. It will be set by the tag handler, and the body will be called repeatedly.

### The tag handler `doTag()` method

```java
String[] movies = {"Monsoon Wedding", "Saved!", "Fahrenheit 9/11"};

public void doTag() throws JspException, IOException {
  for(int i = 0; i < movies.length; i++) {
    getJspContext().setAttribute("movie", movies[i]);
    getJspBody().invoke(null);
  }
}
```

Set the attribute value to be the next element in the array.

Invoke the body again.

Each loop of the Tag handler resets the "movie" attribute value and calls `getJspBody().invoke()` again.
A Simple tag with an attribute

If the tag needs an attribute, you declare it in the TLD, and provide a bean-style setter method in the tag handler class for each attribute. If the tag invocation includes attributes, the Container invokes a setter method for each attribute.

The JSP tag invocation

```
<table>
  <myTags:simple5 movieList="${movieCollection}">
    <tr>
      <td>${movie.name} </td>
      <td>${movie.genre} </td>
    </tr>
  </myTags:simple5>
</table>
```

It's just an attribute like any other tag attribute. It doesn't matter that it's a Simple Tag handler taking care of the tag.

The tag handler class

```java
public class SimpleTagTest5 extends SimpleTagSupport {
    private List movieList;

    public void setMovieList(List movieList) {
        this.movieList = movieList;
    }

    public void doTag() throws JspException, IOException {
        Iterator i = movieList.iterator();
        while (i.hasNext()) { 
            Movie movie = (Movie) i.next();
            getJspContext().setAttribute("movie", movie);
            getJspBody().invoke(null);
        }
    }
}
```

We're not showing the imports.

Write a bean-style setter method for the attribute. The method name MUST match the attribute name in the TLD (remove the "set" prefix and changing the case of the first letter).

The TLD for the tag

```
<tag>
  <description>takes an attribute and iterates over body</description>
  <name>simple</name>
  <tag-class>foo.SimpleTagTest5</tag-class>
  <body-content>scriptless</body-content>
  <attribute>
    <name>movieList</name>
    <required>true</required>
    <rtnexpvalue>true</rtnexpvalue>
  </attribute>
</tag>
```

Use a regular `<tag>` attribute declaration in the TLD, just like other custom tags (with the exception of Tag Files). You are here.
What exactly is a JspFragment?

A JspFragment is an object that represents JSP code. Its sole purpose in life is to be invoked. In other words, it’s something that’s meant to run and generate output. The body of a tag that invokes a simple tag handler is encapsulated in the JspFragment object, then sent to the tag handler in the setJspBody() method.

The crucial thing you must remember about JspFragment is that it must NOT contain any scripting elements. It can contain template text, standard and custom actions, and EL expressions, but no scriptlets, declarations, or scripting expressions.

One cool thing is that since it’s an object, you can even pass the fragment around to other helper objects. And those objects, in turn, can get information from it by invoking the JspFragment’s other method—getJspContext(). And of course once you’ve got a context, you can ask for attributes. So the getJspContext() method is really a way for the tag body to get information to other objects.

Most of the time, though, you’ll use JspFragment simply to output the body of the tag to the response. You might, however, want to get access to the contents of the body. Notice that JspFragment doesn’t have an access method like getContents() or getBody(). You can write the body to something, but you can’t directly get the body. If you do want access to the body, you can use the argument to the invoke() method to pass in a java.io.Writer, then use methods on that Writer to process the contents of the tag body.

For the exam, and real life, this is probably all you will ever need to know about the details of JspFragment, so we won’t spend any more time on it in the book.
**SkipPageException: stops processing the page...**

Imagine you’re in a page that invokes the tag, and the tag depends on specific request attributes (that it gets from the JspContext available to the tag handler).

Now imagine the tag can’t find the attributes it needs, and that the tag knows the rest of the page will never work if the tag can’t succeed. What do you do? You could have the tag throw a JspException, and that would kill the page... but what if it’s only the rest of the page that won’t work? In other words, what if you still want the first part of the page—the part of the page that’s evaluated before the tag invocation—to still appear as the response, but you don’t want the response to include anything still left to be processed after the tag throws an exception?

No problem. That’s exactly why SkipPageException exists.

**The tag handler doTag() method**

```java
public void doTag() throws JspException, IOException {
    JspContext jspCtx = this.getJspContext();
    getJspContext().getOut().println("Message from within doTag().<br>");
    if (thingsDoNotWork) {
        throw new SkipPageException();
    }
}
```

**The JSP that invokes the tag**

```jsp
<%@ taglib prefix="myTags" uri="simpleTags" %>
<html><body>
About to invoke a tag that throws SkipPageException<br>
<myTags:skipList/>
<br>Back in the page after invoking the tag.
</body></html>
```

---

**Sharpen your pencil**

What is the result if the thingsDoNotWork test is false?

Fill in what you’ll see in the browser:

![Browser screenshot](image-url)
SkipPageException shows everything up to the point of the exception

Everything in the doTag() method up to the point of the SkipPageException still shows up in the response. But after the exception, anything still left in either the tag or the page won’t be evaluated.

In the JSP

```jsp
<%@ taglib prefix="myTags" url="simpleTags" %>
<html><body>
About to invoke a tag that throws SkipPageException <br>
<myTags:simple6/>

<br>Back in the page after invoking the tag.
</body></html>
```

In the tag handler

```java
public void doTag() throws JspException, IOException {
    getJspContext().getOut().print("Message from within doTag().<br>");
    getJspContext().getOut().print("About to throw a SkipPageException");
    if (thingsDontWork) {
        throw new SkipPageException();
    }
}
```

This doesn’t print out!
But what happens when the tag is invoked from an included page?

Look at the code below and figure out what prints when you bring up PageA.
*Hint: look in the API for javax.servlet.jsp.SkipPageException.*

Fill in what you’ll see in the browser:

---

PageA JSP that includes PageB

```html
<html>
<body>
  This is page (A) that includes another page (B).<br>
  Doing the include now:<br>
  <%jsp:include page="badTagInclude.jsp" /%>
  Back in page A after the include...
</body>
</html>
```

PageB (the included file) JSP that invokes the bad tag

```jsp
<%@ taglib prefix="myTags" uri="simpleTags" %>
This is page B that invokes the tag that throws SkipPageException.
Invoking the tag now:<br>
<myTags: simple6/>
<br>Still in page B after the tag invocation...
```

The tag handler doTag() method

```java
public void doTag() throws JspException, IOException {
    getJspContext().getOut().print("Message from within doTag()...");
    getJspContext().getOut().print("About to throw a SkipPageException");
    throw new SkipPageException();
}
```

---

*You are here*
**SkipPageException behavior**

**SkipPageException stops only the page that directly invoked the tag**

If the page that invokes the tag was included from some other page, only the page that invokes the tag stops processing! The original page that did the include keeps going after the SkipPageException.

---

**PageA JSP that includes PageB**

```html
<html><body>
   This is page (A) that includes another page (B).<br />
   Doing the include now:<br />
   <jsp:include page="badTags/include.jsp" />
   Back in page A after the include...
</body></html>
```

**PageB (the included file) JSP that invokes the bad tag**

```jsp
taglib prefix="myTags" uri="simpleTags" />
   This is page B that invokes the tag that throws SkipPageException. Invoking the tag now:<br />
   <myTags:simple6 />
   <br />
   Still in page B after the tag invocation...
```

**The tag handler doTag() method**

```java
public void doTag() throws JspException, IOException {
   getJspContext().out().println("Message from within doTag()");
   getJspContext().out().println("About to throw a SkipPageException");
   throw new SkipPageException();
}
```

---

516 chapter 10
The only way you can set an attribute value for something that can't be expressed as a String in the tag. In other words, you can't send a Dog into the tag if you're forced to represent the Dog as a String literal. But if you can use an expression for the value of the attribute, then that expression can evaluate to whatever object type you need to match the argument to the handler's corresponding setter method.

Q: In a SimpleTag handler, if the tag is declared to have a body but it is invoked using an empty tag (since there's no way to say that a body is required), is the setJspBody() still invoked?

A: No! The setJspBody() is invoked ONLY if these two things are true:
1) The tag is NOT declared in the TLD to have an empty body.
2) The tag is invoked with a body. That means that even if the tag is declared to have a non-empty body, the setJspBody() method will not be called if the tag is invoked in either of these two ways:
   <tag></tag> (empty tag)
   <tag></tag> (no body).
Simple Tag bullet points

- Tag Files implement tag functionality using a page, while tag handlers implement tag functionality using a Java tag handler class.
- Tag handlers come in two types: **Classic** and Simple (Simple tags and Tag Files were added in JSP 2.0).
- To make a Simple tag handler, extend SimpleTagSupport (which implements the SimpleTag interface).
- To deploy a Simple tag handler, you must create a TLD that describes the tag using the same <tag> element used by JSTL and other custom tag libraries.
- To use a Simple tag with a body, make sure the TLD <tag> for this tag does not declare <body-content> empty. Then call getJspBody().invoke() to cause the body to be processed.
- The SimpleTagSupport class includes implementation methods for everything in the SimpleTag interface, plus three convenience methods including getJspBody(), which you can use to get access to the contents of the body of the tag.
- The Simple tag lifecycle: **Simple tags are never reused by the Container**, so each time a tag is invoked, the tag handler is instantiated, and its setJspContext() method is invoked. If the tag is called from within another tag, the setParent() method is called. If the tag is invoked with attributes, a bean-style setter method is invoked for each attribute. If the tag is invoked with a body (assuming its TLD does NOT declare it to have an empty body), the setJspBody() method is invoked. Finally, the doTag() method is invoked, and when it completes, the tag handler instance is destroyed.
- The setJspBody() method will be invoked ONLY if the tag is actually called with a body. If the tag is invoked without a body, either with an empty tag <my:tag> or with nothing between the opening and closing tags <my:tag> or with nothing between the opening and closing tags, the setJspBody() method will NOT be called. Remember, if the tag has a body, the TLD must reflect that, and the <body-content> must not have a value of ‘empty’.
- The Simple tag’s doTag() method can set an attribute used by the body of the tag, by calling getJspContext().setAttribute() followed by getJspBody().invoke().
- The doTag() method declares a JspException and an IOException, so you can write to the JspWriter without wrapping it in a try/catch.
- You can iterate over the body of a Simple tag by invoking the body (getJspBody().invoke()) in a loop.
- If the tag has an attribute, declare the attribute in the TLD using an <attribute> element, and provide a bean-style setter method in the tag handler class. When the tag is invoked, the setter method will be called before doTag()).
- The getJspBody() method returns a JspFragment, which has two methods: invoke(java.io.Writer) and getJspContext() that returns a JspContext the tag handler can use to get access to the PageContext API (to get access to implicit variables and scoped attributes).
- Passing null to invoke() writes the evaluated body to the response output, but you can pass another Writer in if you want direct access to the body contents.
- Throw a SkipPageException if you want the current page to stop processing. If the page that invoked the tag was included from another page, the including page keeps going even though the included page stops processing from the moment the exception is thrown.
You still have to know about Classic tag handlers

You might get lucky. Maybe the place you work is starting out with JSP 2.0, and can use Tag Files and Simple-Tag handlers from the start.

That _could_ happen.

But it probably won’t. Chances are, you’re working (or will work in the future) somewhere that’s been using JSPs since the pre-2.0 days, using the Classic tag model for writing custom tag handlers.

You probably need to at least be able to read the source code for a Classic tag handler. You might be called on to maintain or refactor a Classic tag handler class.

But even if you don’t ever have to read or write a Classic tag handler, they’re still covered (very lightly) by one of the exam objectives. Be grateful—on the previous version of the exam you might have seen at least seven or eight Classic tag handler questions on the exam.

Today, exam candidates will see only a couple of questions on Classic tag handlers.
Chapter 10. When even JSTL is not enough...

Tag API

Tag handler API

Everything in a grey box is from the original (Classic) tag model for custom tag handlers.

SimpleTag interface

```
void doTag()
SimpleTag
```

Tag interface

```
int doEndTag()
tagParent()
int doStartTag()
void setParent(PageContext)
void release()
Tag
```

SimpleTagSupport class

```
void doTag()
JspTag findAncestorWithClass(JspTag, JspTag, Class)
JspFragment getJspBody()
JspContext getJspContext()
JspTag getParent()
setJspBody(JspFragment)
setJspContext(JspContext)
setParent(JspTag)
SimpleTagSupport
```

IterationTag interface

```
int doAfterBody()
IterationTag
```

BodyTag interface

```
void doAfterBody()
BodyTag
```

TagSupport class

```
void doAfterBody()
int doStartTag()
int doEndTag()
void setParent(PageContext)
if more methods...
TagSupport
```

BodyTagSupport class

```
void doAfterBody()
setBodyContent(BodyContent)
if more methods...
BodyTagSupport
```

This side (with the grey boxes) is the Classic tag API. The JspTag superinterface was added with JSP 2.0, but it doesn’t affect the Classic tag API.

The tag handler API has five interfaces and three support classes. There’s virtually NO reason to implement the interfaces directly; so you’ll probably always extend a support class.
custom tag development

A very small Classic tag handler

This example is so basic that it’s not much different from a SimpleTag handler’s doTag() method. In fact the differences won’t become painful until you try to process a tag with a body (but you’ll just have to wait for that).

A JSP that invokes a Classic tag

```jsp
taglib prefix="mine" uri="KathyClassicTags" />
<html>
<body>
    <mine:classicOne />
</body></html>
```

The TLD <tag> element for the Classic tag

```html
<tag>
    <description>ludicrous use of a Classic tag</description>
    <name>classicOne</name>
    <tag-class>foo.Classic1</tag-class>
    <body-content>empty</body-content>
</tag>
```

The Classic tag handler

```java
package foo;
import javax.servlet.jsp. *
import javax.servlet.jsp.tagext. *
import java.io. *

public class Classic1 extends TagSupport {
    public int doStartTag() throws JspException {
        JspWriter out = pageContext . getOut();
        try {
            out.println("classic tag output");
            catch (IOException ex) {
                throw new JspException("IOException- " + ex . toString());
        }
        return SKIP_BODY;
    }
}
```

Chapter 10. When even JSTL is not enough...
**Classic tag**

### A Classic tag handler with TWO methods

This example overrides both the doStartTag() and doEndTag() methods, although it could accomplish the same output all within doStartTag(). The point of doEndTag() is that it’s called *after* the body is evaluated. We don’t show the TLD here, because it’s virtually identical to the previous one, except for some of the names. The tag is declared to have no attributes, and an empty body.

#### A JSP that invokes a Classic tag

```jsp
<%@ taglib prefix="mine" uri="KathyClassicTags" %>
<html><body>
  Classic Tag Two: chr
  <mine:classicTwo />
</body></html>
```

**The Classic tag handler**

```java
public class Classic2 extends TagSupport {
  JspWriter out;

  public int doStartTag() throws JspException {
    try {
      return SKIP_BODY;
    } catch (IOException ex) {
      throw new JspException("IOException- " + ex.toString());
    }
    return SKIP_BODY;
  }

  public int doEndTag() throws JspException {
    try {
      return EVAL_PAGE;
    } catch (IOException ex) {
      throw new JspException("IOException- " + ex.toString());
    }
    return EVAL_PAGE;
  }
}
```

Classic Tag Two:

in doStartTag() in doEndTag()
When a tag has a body: comparing Simple vs. Classic

Now it starts to look different from a SimpleTag. Remember, SimpleTag bodies are evaluated when (and if) you want by calling invoke() on the JspFragment that encapsulates the body. But in Classic tags, the body is evaluated in between the doStartTag() and doEndTag() methods! Both of the examples below have the exact same behavior.

The JSP that uses the tag

```jsp
<%@ taglib prefix="myTags" uri="myTags" %>
<html>
<body>
   <myTags:simpleBody>
      This is the body
   </myTags:simpleBody>
</body></html>
```

A SimpleTag handler class

```java
// package and imports
public class SimpleTagTest extends SimpleTagSupport {
   public void doTag() throws JspException, IOException {
      getJspContext().getOut().println("Before body.");
      getJspBody().invoke(null); // This causes the body to be evaluated.
      getJspContext().getOut().println("After body.");
   }
}
```

A Classic tag handler that does the same thing

```java
// package and imports
public class ClassicTest extends TagSupport {
   JspWriter out;
   public int doStartTag() throws JspException {
      out = pageContext.getOut();
      try {
         out.println("Before body.");
         catch (IOException ex) {
            throw new JspException("IOException- " + ex.toString());
         }
         return EVAL_BODY_INCLUDE;  <-- THIS is what causes the body to be evaluated in a Classic tag handler!
      }
   }
   public int doEndTag() throws JspException {
      try {
         out.println("After body.");
         catch (IOException ex) {
            throw new JspException("IOException- " + ex.toString());
         }
         return EVAL_PAGE;
      }
   }
}
```
But how do you loop over the body? It looks like doStartTag() is called too early, and doEndTag() is too late, and I don’t have any way to keep re-invoking the body evaluation...

iterating with Classic tags?

Simple tag

```
// package and imports
public class SimpleTagTest extends SimpleTagSupport {
    public void doTag() throws JspException, IOException {
        for(int i = 0; i < 3; i++) {
            JspBody.invoke(null);
        }
    }
}
```

```
It’s easy to loop the body of a Simple tag; you just keep calling invoke() on the body, from within doTag().
```

```
Classic tag

// package and imports
public class ClassicTest extends TagSupport {
    public int doStartTag() throws JspException {
        return EVAL_BODY_INCLUDE;
    }
}
```

```
But where do you loop over the body, if the body is evaluated in between the methods instead of IN a method like doTag()?
```

```
public int doEndTag() throws JspException {
    return EVAL_PAGE;
}
```
**Classic tags have a different lifecycle**

Simple tags are simple—it’s all about `doTag()`. But with classic tags, there’s a `doStartTag()` and a `doEndTag()`. And that brings up an interesting problem—when and how is the body evaluated? There’s no `doBody()` method, but there is a `doAfterBody()` method that’s called *after* the body is evaluated and before the `doEndTag()` runs.

---

**Custom tag development**

- **Web Container**: Load class, Instantiate class (no-arg constructor runs), Call the `setPageContext(PageContext)` method.
- **Classic tag class**: If the tag is nested (invoked from within another tag), call the `setParent(Tag)` method.
- **Tag Handler Object**: If the tag has attributes, call attribute setters.
- **Classic tag class**: Call the `doStartTag()` method.
- **Tag Handler Object**: If the tag is NOT declared to have an empty body, AND the tag is NOT invoked with an empty body, AND the `doStartTag()` method returns `EVAL_BODY_INNER`, the body is evaluated.
- **Classic tag class**: If the body content was evaluated, call the `doAfterBody()` method.
- **Tag Handler Object**: Call the `doEndTag()` method.

---

There happen the first time the tag is invoked, but the Container may (depending on the circumstances) reuse the Classic tag object after this.

This gives the handler a reference to a `PageContext`.

A nested tag can communicate with the other tags in which its nested.

If the tag is invoked with attributes, the JavaBean-style setter for each attribute is called (just as with Simple Tag handlers).

The body is evaluated between the `doStartTag()` and `doEndTag()` methods.

`doAfterBody()` lets you do things **after** the body runs, and unlike the other methods it can be invoked more than once.

`doEndTag()` is always called once, either after `doStartTag()` or after `doAfterBody()`.

---

*you are here → 525*
Chapter 10. When even JSTL is not enough...

**Classic tag lifecycle**

**The Classic lifecycle depends on return values**

The `doStartTag()` and `doEndTag()` methods return an int. That int tells the Container what to do next. With `doStartTag()`, the question the Container asks is, “Should I evaluate the body?” (assuming there is one, and assuming the TLD doesn’t declare the body as empty).

With `doEndTag()`, the Container asks, “Should I keep evaluating the rest of the calling page?” The return values are represented by constants declared in the `Tag` and `IterationTag` interfaces.

**Possible return values when you extend TagSupport**

- **doStartTag()**
  - SKIP_BODY
  - EVAL_BODY_INCLUDE

- **doAfterBody()**
  - SKIP_BODY
  - EVAL_BODY_AGAIN

- **doEndTag()**
  - SKIP_PAGE
  - EVAL_PAGE

![Diagram](attachment:diagram.png)

The constants used as return values for `doStartTag()` and `doEndTag()` return value constants are inconsistently named!

With `doStartTag()`, the return values are SKIP_BODY and EVAL_BODY_INCLUDE. But with `doEndTag()`, the values are SKIP_PAGE and EVAL_PAGE.

If the names were consistent, `doEndTag()` would return EVAL_PAGE_INCLUDE (as opposed to EVAL_PAGE). To match the way `doStartTag()` returns EVAL_BODY_INCLUDE, But it’s not! So don’t be fooled if you see code on the exam with correct-looking (but wrong) return values.

Returning SKIP_PAGE from `doEndTag()` is exactly like throwing a SkipPageException from a Simple tag if a page included the page that invoked the tag. The current (included) page stops processing, but the including page continues.

Chapter 10. When even JSTL is not enough...
**IterationTag lets you repeat the body**

When you write a tag handler that extends TagSupport, you get all the lifecycle methods from the Tag interface, plus the one method from IterationTag—doAfterBody(). Without doAfterBody(),
you can’t iterate over the body because doStartTag() is too early, and doEndTag() is too late. But with doAfterBody(), your return value tells the Container whether it should repeat the body again (EVAL_BODY_AGAIN) or call the doEndTag() method (SKIP_BODY).

```
public void doTag() throws JspException, IOException {
    String[] movies = {"Spiderman", "Saved!", "Amelie"};
    for(int i = 0; i < movies.length; i++) {
        getJspContext().setAttribute("movie", movies[i]);
        getJspBody().invoke(null);
    }
}
```

// package and imports
public class MyIterationTag extends TagSupport {

    public int doStartTag() throws JspException {

        public int doAfterBody() throws JspException {

        public int doEndTag() throws JspException {
```
Classic tag exercise

BE the Container
Look at the legal tag handler code below and figure out whether it would give you the result shown, given the JSP tag invocation listed below. This is also the same result produced by the ClassicTag handler from the previous page. Yes, we’re answering the Sharpen Your Pencil with yet another exercise...

The tag handler class

```java
// package and imports
public class MyIteratorTag extends TagSupport {
    String[] movies = new String[] {"Spiderman", "Saved!", "Amelie"};
    int movieCounter;

    public int doStartTag() throws JspException {
        movieCounter=0;
        return EVAL_BODY_INCLUDE;
    }

    public int doAfterBody() throws JspException {
        if (movieCounter < movies.length) {
            pageContext.setAttribute("movie", movies[movieCounter]);
            movieCounter++;
            return EVAL_BODY_AGAIN;
        } else {
            return SKIP_BODY;
        }
    }

    public int doEndTag() throws JspException {
        return EVAL_PAGE;
    }
}
```

JSP that invokes the tag

```html
<%@ taglib prefix="mine" uri="KathyClassicTags" %>
<html><body>
<table border="1">
    <tr><td>${movie}</td></tr>
    <tr><td>${movies}</td></tr>
</table>
</body></html>
```

Desired result

![Spiderman, Saved!, Amelie](image.png)

528 chapter 10
## Default return values from TagSupport

If you don’t override the TagSupport lifecycle methods that return an integer, be aware of the default values the TagSupport method implementations return. The TagSupport class assumes that your tag doesn’t have a body (by returning SKIP_BODY from doStartTag()), and that if you DO have a body that’s evaluated, you want it evaluated only once (by returning SKIP_BODY from doAfterBody()). It also assumes that you want the rest of the page to evaluate (by returning EVAL_PAGE from doEndTag()).

### Default return values when you don’t override the TagSupport method implementation

<table>
<thead>
<tr>
<th>doStartTag()</th>
<th>doAfterBody()</th>
<th>doEndTag()</th>
</tr>
</thead>
<tbody>
<tr>
<td>SKIP_BODY</td>
<td>SKIP_BODY</td>
<td>SKIP_PAGE</td>
</tr>
<tr>
<td>EVAL_BODY_INCLUDE</td>
<td>EVAL_BODY_AGAIN</td>
<td>EVAL_PAGE</td>
</tr>
</tbody>
</table>

The TagSupport class assumes your tag doesn’t have a body, or that if the body IS evaluated, that the body should be evaluated only **ONCE**.
It also assumes that you always want the rest of the page to be evaluated.

---

**You MUST override doStartTag() if you want the tag body to be evaluated!!**

Think about it! The default return value from doStartTag() is SKIP_BODY, so if you want the body of your tag evaluated, and you extend TagSupport, you **MUST** override doStartTag() if for no other reason than to return EVAL_BODY_INCLUDE.
With doAfterBody(), it should be obvious that if you want to iterate over the body, you have to override that method as well, since its return value is SKIP_BODY.
Classic tag exercise answers

BE the Container Answer

Desired result

Actual result (unless you add the two lines highlighted below)

The tag handler class

public class MyIteratorTag extends TagSupport {
    String[] movies = new String[] {"Spiderman", "Saved!", "Amelie"};
    int movieCounter;

    public int doStartTag() throws JspException {
        movieCounter = 0;
        pageContext.setAttribute("movie", movies[movieCounter]);
        movieCounter++;
        return EVAL_BODY_INCLUDE;
    }

    public int doAfterBody() throws JspException {
        if (movieCounter < movies.length) {
            pageContext.setAttribute("movie", movies[movieCounter]);
            movieCounter++;
            return EVAL_BODY_AGAIN;
        } else {
            return SKIP_BODY;
        }
    }

    public int doEndTag() throws JspException {
        return EVAL_PAGE;
    }
}

JSP that invokes the tag

<%@ taglib prefix="mine" uri="KathyClassicTags" %>
<html><body>
<table border="1">
<tr><td><mine:iterateMovies>
<td>${movie}</td></tr></mine:iterateMovies>
</table>
</body></html>

530 chapter 10
Q: This seems stupid—there’s duplicate code in doStartTag() and doAfterBody().

A: Yes, there’s duplicate code. In this case, if you’re implementing TagSupport, and you want to set values the body can use, then you MUST set those attribute values in doStartTag(). You can’t wait until doAfterBody(), because by the time you get to doAfterBody(), the body has already been processed once. Yes, it’s kind of stupid. Which is why SimpleTag is so much better. Of course if you were writing the code, you’d make a private method in your tag handler... say, setMovie(), and you’d call that method from both doStartTag() and doAfterBody(). But it’s still an awkward approach.

Q: WHY are you setting the instance variable value for movieCounter INSIDE the doStartTag() method? Why can’t you just initialize it when you declare it?

A: Yikes! Unlike SimpleTag handlers, which are never reused, a Classic tag handler can be pooled and reused by the Container. That means you’d better reset your instance variable values with each new tag invocation (which means in doStartTag()). Otherwise, this code works the first time, but the next time a JSP invokes it, the movieCounter variable will still have its last value, instead of 0!
**BodyTag interface**

**But what if you DO need access to the body contents?**

You’ll probably find that most of the time the lifecycle methods from the Tag and IterationTag interfaces, as provided by TagSupport, are enough. Between the three key methods (doStartTag(), doAfterBody(), and doEndTag()), you can do just about anything.

Except...you don’t have direct access to the contents of the body. If you need access to the actual body contents, so that you can, say, use it in an expression or perhaps filter or alter it in some way, then extend BodyTagSupport instead of TagSupport, and you’ll have access to the BodyTag interface methods.

---

**Adding the BodyTagSupport interface to your tag.**

Extending BodyTagSupport gives you two more lifecycle methods from the BodyTag interface—setBodyContent() and doInitBody(). You can use these to do something with the actual CONTENTS of the body of the tag used to invoke the handler.

---

**Chapter 10. When even JSTL is not enough...**

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: O'Reilly

With **BodyTag**, you get two new methods

When you implement **BodyTag** (by extending **BodyTagSupport**), you get two more lifecycle methods—**setBodyContent()** and **doInitBody()**. You also get one new return value for **doStartTag()**, **EVAL_BODY_BUFFERED**. That means there are now **three** possible return values for **doStartTag()**, instead of the **two** you get when you extend **TagSupport**.

**Lifecycle for a tag that implements BodyTag**

(directly or by extending **BodyTagSupport**)

A change in the default return value for **BodyTagSupport**:

- **doStartTag()**
  - **SKIP_BODY**
  - **EVAL_BODY_INCLUDE**
  - **EVAL_BODY_BUFFERED**

New return value, and it’s the default for **BodyTagSupport** (instead of **SKIP_BODY**, the default for **TagSupport**).
**BodyTag and BodyTagSupport**

**With BodyTag, you can buffer the body**

The `BodyContent` argument to `setBodyContent()` is actually a type of `java.io.Writer`. (Yes, it’s OK to find that disturbing from an OO perspective.) But that means you can process the body by, say, chaining it to another IO stream or getting the raw bytes.

**Q:** What happens if I return `EVAL_BODY_BUFFERED` even though the invoking tag is empty?

**A:** The `setBodyContent()` and `doInitTag()` method will not be called if the tag invoking the handler is empty! And by empty, we mean that the tag was invoked using an empty tag `<my:tag/>` or with no content between the opening and closing tags `<my:tag/>`.<br>

The Container knows there’s no body this time, and it just skips to the `doEndTag()` method, so this is usually not a problem.

**Unless the TLD declares the tag to have an empty body!** If the TLD says `<body-content empty>` (or `empty`), you don’t have a choice, and you must NOT return `EVAL_BODY_BUFFERED` or `EVAL_BODY_INCLUDE` from `doStartTag()`.

**Q:** What about attributes in a Classic tag? Are they handled the same way as with Simple tags?

**A:** Yes, on the sequence diagram for both Simple tag handlers and Classic tag handlers, there was a place where bean-style setter methods are called for each attribute. This happens before a Simple tag’s `doTag()` or a Classic tag’s `doStartTag()` method. In other words, tag attributes work in exactly the same way for both Classic and Simple tags, including the way in which they’re declared in the TLD.
**custom tag development**

### Lifecycle methods for Classic tag methods

Fill in the chart below. We’ve covered almost everything you need to do this correctly, but you’ll have to guess in a few places. (Don’t turn the page!)

<table>
<thead>
<tr>
<th>Method</th>
<th>BodyTagSupport</th>
<th>TagSupport</th>
</tr>
</thead>
<tbody>
<tr>
<td>doStartTag()</td>

</table>
What if you have tags that work together?

Imagine this scenario... you have a `<my:Menu>` tag that builds a custom navigation bar. It needs menu items. So you use a `<my:MenuItem>` tag nested within the `<my:Menu>` tag, and the menu tag gets ahold (somehow) of the menu items and uses those items to build the navigation bar.

```xml
<my:Menu>
  <my:MenuItem itemValue="Dogs" />
  <my:MenuItem itemValue="Cats" />
  <my:MenuItem itemValue="Horses" />
</my:Menu>
```

The big question is, how do the tags talk to one another? In other words, how does the Menu tag (the enclosing tag) get the attribute values from the MenuItems (the inner/nested tags)?

Nested tags are used in several places in the JSTL: the `<choose>` tag, with its nested `<when>` and `<otherwise>` tags, is a good example. And you might need to use “cooperating tags” (that’s how the spec says it) in your own custom development as well.

Fortunately, there’s a mechanism for getting info to and from outer and inner tags, regardless of the depth of nesting. That means you can get info from a deeply nested tag out to not just the tag’s immediate enclosing tag, but to any arbitrary tag up the tag nesting hierarchy.

---

**Sharpen your pencil**

Look at the Tag API, review the previous tag handler code, and think about how cooperating tags might get info to and from one another.
the `getParent()` method

A Tag can call its Parent Tag

Both SimpleTag and Tag have a `getParent()` method. The `getParent()` in Tag returns a Tag, but the `getParent()` in SimpleTag returns an instance of `JspTag`. We’ll see the implications of those return types in a minute.

```
  <interface>
  JspTag
  </interface>

  <interface>
  SimpleTag
  </interface>

  void doStartTag()
  JspTag getParent()
  void setJspBody(JspFragment)
  void setJspContext(JspContext)
  void setParent(JspTag parent)

  <interface>
  Tag
  </interface>

  int doEndTag()
  Tag getParent()
  int doStartTag()
  void setPageContext(PageContext)
  void setParent(Tag)
  void release()
```

A nested tag can access its parent (enclosing) tag

```
<mine:OuterTag>
  <mine:InnerTag />
</mine:OuterTag>
```

Getting the parent tag in a Classic tag handler

```
public int doStartTag() throws JspException {
    OuterTag parent = (OuterTag) getParent();
    // do something with it
    return EVAL_BODY_INCLUDE;
}
```

Getting the parent tag in a Simple tag handler

```
public void doTag() throws JspException, IOException {
    OuterTag parent = (OuterTag) getParent();
    // do something with it
}
```
Find out just how deep the nesting goes...

You can walk your way up the ancestor tag chain by continuing to call getParent() on whatever is returned by getParent(). Because getParent() returns either another tag (on which you can call getParent()), or null.

In a JSP

```jsp
<%doSomethingTag%>
<%doSomethingTag%>
<%doSomethingTag%/>
</%doSomethingTag%>
</%doSomethingTag%>
```

In a Classic tag handler

```java
package foo;
import javax.servlet.jsp.;
import javax.servlet.jsp.tagext.*;
import java.io.*;
public class NestingLevelTag extends TagSupport {
    private int nestLevel = 0;
    public int doStartTag() throws JspException {
        Tag parent = getParent();
        if (parent != null) {
            parent = parent.getParent();
            nestLevel++;
        }
        try {
            pageContext.getOut().println("Tag nested level: "+ nestLevel);
        } catch (IOException ex) {
            throw new JspException("IOException- " + ex.getMessage());
        }
        return EVAL_BODY_INCLUDE;
    }
}
```

Result

Tag nested level: 0
Tag nested level: 1
Tag nested level: 2
Simple tags can have Classic parents

This is not a problem, because a SimpleTag’s getParent() returns type JspTag, and Classic tags and Simple tags now share the JspTag super interface. Actually, Classic tags can have Simple parents, but it takes a slight hack to make that work because you can’t cast a SimpleTag to the Tag return value of the Tag interface getParent(). We won’t go into how to access a Simple tag parent from a Classic child tag, but all you need to know for the exam (and almost certainly real web app life) is that by using getParent(), a Classic tag can access Classic tag parents, and a Simple tag can access either a Classic or Simple parent.

In a JSP

```<%@ taglib prefix="c" uri="http://java.sun.com/jsp/jstl/core" %>
<c:out value="Hello World"/>
```
You can walk up, but you can't walk down...

There's a `getParent()` method, but there's no `getChild()`. Yet the scenario we showed earlier was for an outer `<my:Menu>` tag that needed access to its nested `<my:MenuItem>` tags. What can we do? How can the parent tag get information about the child tags, when a child can get a reference to the parent, but the parent can’t ask for a reference to the child?

It's tragic. My child can find me, his parent, but I have no way to find my child! I just have to wait for him to call ME...

That is so sad...

Sharpen your pencil

How could a parent tag get attribute values from a child tag? Describe how you would implement the functionality of the cooperating Menu and MenuItem tags.
sending info to the parent

Getting info from child to parent

We have two main ways in which tags can cooperate with one another:
1) The child tag needs info (like an attribute value) from its parent tag.
2) The parent tag needs info from each of its child tags.

We’ve already seen how the first scenario works—the child tag gets a reference to its parent using getParent(), then calls getter methods on the parent. But what happens when the parent needs info from the child? We have to do the same thing. In other words, if the parent needs info from the child, it’s the child’s job to give it to the parent!

Since there’s no automatic mechanism for the parent to find out about its child tags, you simply have to use the same design approach to get info to the parent from the child as you do to get info from the parent to the child. You get a reference to the parent tag, and call methods. Only instead of getters, this time you’ll call some kind of set or add method.

In a JSP

```jsp
taglib prefix="mine" uri="KathyClassicTags" %
<html><body>
  <mine:Menu>
    <mine:MenuItem itemValue="Dogs" />
    <mine:MenuItem itemValue="Cats" />
    <mine:MenuItem itemValue="Horses" />
  </mine:Menu>
</body></html>
```

Result

Menu items are: [Dogs, Cats, Horses]

In this example we didn’t actually do anything with the menu items except prove that we got them, but you can imagine that we might use the items to build a navigation bar, for example...
Menu and MenuItems tag handlers

In the child tag: MenuItem

```java
public class MenuItem extends TagSupport {
    private String itemValue;

    public void setItemValue(String value) {
        itemValue = value;
    }

    public int doStartTag() throws JspException {
        return EVAL_BODY_INCLUDE;
    }

    public int doEndTag() throws JspException {
        Menu parent = (Menu) getParent();
        parent.addMenuitem(itemValue);
        return EVAL_PAGE;
    }
}
```

In the parent tag: Menu

```java
public class Menu extends TagSupport {
    private ArrayList items;

    public void addMenuItem(String item) {
        items.add(item);
    }

    public int doStartTag() throws JspException {
        items = new ArrayList();
        return EVAL_BODY_INCLUDE;
    }

    public int doEndTag() throws JspException {
        try {
            pageContext.getOut().println("Menu items are: " + items);
        } catch (Exception ex) {
            throw new JspException("Exception: " + ex.toString());
        }
        // Imagine complex menu-building code here...
        return EVAL_PAGE;
    }
}
```
Finding an ancestor

Getting an arbitrary ancestor

There is another mechanism you can use if you want to, say, skip some nesting levels and go straight to a grandparent or something even further up the tag nesting hierarchy. The method is in both TagSupport and SimpleTagSupport (although they have slightly different behavior), and it’s called findAncestorWithClass().

Getting an immediate parent using getParent()

```
OuterTag parent = (OuterTag) getParent();
```

Getting an arbitrary ancestor using findAncestorWithClass()

```
WayOuterTag ancestor = (WayOuterTag) findAncestorWithClass(this, WayOuterTag.class);
```

`findAncestorWithClass(this, WayOuterTag.class);`

```
starting tag

↑

the class of the tag you want
```

The Container walks the tag nesting hierarchy until it finds a tag that’s an instance of this class. It returns the first one, so there’s no way to say “skip the first tag you see that’s an instance of WayOuterTag, class and give me the second instance instead.” So if you really know for a fact that you wanted the second instance of a tag ancestor of that type, you’ll just have to get the return value of findAncestorWithClass(), and then call getParent() or findAncestorWithClass() on it.

You will not be tested on any details of using findAncestorWithClass(). All you need to know for the exam is that it exists!
## Key differences between Simple and Classic tags

</tbody>
</table>
| **How you access implicit variables and scoped attributes from a support implementation** | With the getJspContext() method that returns a JspContext (which is usually a PageContext) | With the pageContext implicit variable— NOT a method like it is with SimpleTag!
| **How you cause the body to be processed** | getJspBody().release(null)                      | Return EVAL_BODY_INCLUDE from doStartTag(), or EVAL_BODY_BUFFERED if the class implements BodyTag |
| **How you cause the current page evaluation to STOP** | Throw a SkipPageException                      | Return SKIP_PAGE from doEndTag()               |
Using the PageContext API for tag handlers

This page is just a review from what you saw in the Script-free JSP chapter, but it comes up again here because it’s crucial for a tag handler. A tag handler class, remember, is not a servlet or a JSP, so it doesn’t have automatic access to a bunch of implicit objects. But it does get a reference to a PageContext, and with it, it can get to all kinds of things it might need.

Remember that while Simple tags get a reference to a JspContext and Classic tags get a reference to a PageContext, the Simple tag’s JspContext is usually a PageContext instance. So if your Simple tag handler needs access to PageContext-specific methods or fields, you’ll have to cast it from a JspContext to the PageContext it really is on the heap.

```
JspContext
getAttribute(String name)
getAttribute(String name, int scope)
getAttributeNamesInScope(int scope)
findAttribute(String name)
getOut()  
// more methods including similar
// methods to set and remove attributes
// from any scope
```

```
PageContext
APPLICATION_SCOPE
PAGE_SCOPE
REQUEST_SCOPE
SESSION_SCOPE
// more fields

getRequest()
getServletConfig()
getServletContext()
getSession()  
// more methods
```

The one-arg `getAttribute(String)` is for page scope ONLY!

There are TWO overloaded `getAttribute()` methods you can call on `PageContext`:

- a one-arg that takes a `String`, and a two-arg that takes a `String` and an `int`.

The one-arg version works just like all the others—it’s for attributes bound TO the pageContext object.

But the two-arg version can be used to get an attribute from ANY of the four scopes.

findAttribute() looks in EACH scope starting with PAGE_SCOPE

You can expect to be tested on this!!! The difference between `getAttribute(String)` and `findAttribute(String)` can be dramatic—the `getAttribute(String)` method looks ONLY in page scope, while the `findAttribute(String)` will search all four scopes to find a matching attribute. In the order of page, request, session, and application. It returns the first one it finds that matches the `findAttribute(String)` argument.
Chapter 10. When even JSTL is not enough...

tag files exercise answers

Memorizing Tag Files
ANSWERS

1. Fill in what would you must put into a Tag File to declare that the Tag has one required attribute, named 'title', that can use an EL expression as the value of the attribute.

   `<@ attribute name="title" required="true" rtexprvalue="true" />`

2. Fill in what would you must put into a Tag File to declare that the Tag must NOT have a body.

   `<@ tag body-content="tagdependent" />`

3. Draw a Tag File document in each of the locations where the Container will look for Tag Files.

   - Directly inside WEB-INF/tags
   - Inside a sub-directory of WEB-INF/tags
   - Inside the META-INF/tags directory inside a JAR file that's inside WEB-INF/lib
   - Inside a sub-directory of META-INF/tags inside a JAR file that's inside WEB-INF/lib
   - IF the tag file is deployed in a JAR, there MUST be a TLD for the tag file.
Mock Exam Chapter 10

1. How can a Classic tag handler to instruct the container to ignore the remainder of the JSP that invoked the tag? (Choose all that apply.)
   - A. The `doEndTag()` method should return `Tag.SKIP_BODY`.
   - B. The `doEndTag()` method should return `Tag.SKIP_PAGE`.
   - C. The `doStartTag()` method should return `Tag.SKIP_BODY`.
   - D. The `doStartTag()` method should return `Tag.SKIP_PAGE`.

2. Which directives and/or standard actions are applicable ONLY within tag files? (Choose all that apply.)
   - A. `tag`
   - B. `page`
   - C. `jsp:body`
   - D. `jsp:doBody`
   - E. `jsp:invoke`
   - F. `taglib`
mock exam

Given a JSP page:
11. `<my:tag1>`
12. `<my:tag2>`
13. `<my:tag3 />`
14. `<my:tag2>`
15. `<my:tag1>`

The tag handler for `my:tag1` is `Tag1Handler` and extends `TagSupport`. The tag handler for `my:tag2` is `Tag2Handler` and extends `SimpleTagSupport`. The tag handler for `my:tag3` is `Tag3Handler` and extends `TagSupport`.

Which is true? (Choose all that apply.)

- A. `Tag3Handler` CANNOT access the instance of `Tag1Handler` because Simple tags do NOT support access to the tag parent.

- B. Only Classic tags are considered in composing the parent/child tag hierarchy; therefore, `Tag3Handler` may use the `getParent` method only once to gain access to the instance of `Tag1Handler`.

- C. `Tag3Handler` may use the `getParent` method twice to gain access to the instance of `Tag1Handler`.

- D. Only BodyTag handlers can access the parent/child tag hierarchy; therefore, `Tag3Handler` CANNOT gain access to the instance of `Tag1Handler`.

Which Simple tag mechanism will tell a JSP page to stop processing?

- A. Return `SKIP_PAGE` from the `doTag` method.

- B. Return `SKIP_PAGE` from the `doEndTag` method.

- C. Throw a `SkipPageException` from the `doTag` method.

- D. Throw a `SkipPageException` from the `doEndTag` method.
custom tag development

5 Which are true about the Classic tag model? (Choose all that apply.)

A. The Tag interface can only be used to create empty tags.

B. The SKIP_PAGE constant is a valid return value of the doEndTag method.

C. The EVAL_BODY_BUFFERED constant is a valid return value of the doAfterBody method.

D. The Tag interface only provides two values for the return value of the doStartTag method: SKIP_BODY and EVAL_BODY.

E. There are three tag interfaces Tag, IterationTag, and BodyTag, but only two built-in base classes: TagSupport and BodyTagSupport.

6 Which about the EndAncestorWithClass method are true? (Choose all that apply.)

A. It requires one parameter: A Class.

B. It is a static method in the TagSupport class.

C. It is a non-static method in the TagSupport class.

D. It is NOT defined by any of the standard JSP tag interfaces.

E. It requires two parameters: A Tag and a Class.

F. It requires one parameter: A String representing the name of the tag to be found.

G. It requires two parameters: A Tag and a String, representing the name of the tag to be found.
Which must be true if you want to use dynamic attributes for a Simple tag handler? (Choose all that apply.)

- A. Your Simple tag must NOT declare any static tag attributes.
- B. Your Simple tag must use the `<dynamic-attributes>` element in the TLD.
- C. Your Simple tag handler must implement the `DynamicAttributes` interface.
- D. Your Simple tag should extend the `DynamicSimpleTagSupport` class, which provides default support for dynamic attributes.
- E. Your Simple tag CANNOT be used with the `jsp:attribute` standard action, because this action works only with static attributes.

Which is true about tag files? (Choose all that apply.)

- A. A tag file may be placed in any subdirectory of `WEB-INF`.
- B. A tag file must have the file extension of `.tag` or `.tagx`.
- C. A TLD file must be used to map the symbolic tag name to the actual tag file.
- D. A tag file may NOT be placed in a JAR file in the `WEB-INF/lib` directory.
Given:

10. public class BuffTag extends BodyTagSupport {
11.   public int doStartTag() throws JspException {
12.     // insert code here
13.   }
14. }

Assume that the tag has been properly configured to allow body content.
Which, if inserted at line 12, would cause the JSP code
<br>`<mytags:mytag>BodyContent</mytags:mytag>`
to output BodyContent?

- A. return SKIP_BODY;
- B. return EVAL_BODY_INCLUDE;
- C. return EVAL_BODY_BUFFERED;
- D. return BODY_CONTENT;

Which about `doAfterBody()` is true? (Choose all that apply.)

- A. `doAfterBody()` is only called on tags that extend `TagSupport`.
- B. `doAfterBody()` is only called on tags that extend `IterationTagSupport`.
- C. Assuming no exceptions occur, `doAfterBody()` is always called after `doStartTag()` for any tag that implements `IterationTag`.
- D. Assuming no exceptions occur, `doAfterBody()` is called after `doStartTag()` for any tag that implements `IterationTag` and returns `SKIP_BODY` from `doStartTag()`.
- E. Assuming no exceptions occur, `doAfterBody()` is called after `doStartTag()` for any tag that implements `IterationTag` and returns `EVAL_BODY_INCLUDE` from `doStartTag()`.
Chapter 10. When even JSTL is not enough...

mock exam

11

Given a JSP page:

1. `<%@ taglib prefix="my" uri="/WEB-INF/myTags.tld" %>`
2. `<my:tag1>`
3. `<%-- JSP content --%>`
4. `</my:tag1>`

The tag handler for `my:tag1` is `TagHandler` and extends `TagSupport`. What happens when the instance of `TagHandler` calls the `getParent` method? (Choose all that apply.)

- A `JspException` is thrown.
- B. The `null` value is returned.
- C. A `NullPointerException` is thrown.
- D. An `IllegalStateException` is thrown.

12

Which is true about the lifecycle of a Simple tag? (Choose all that apply.)

- A. The `release` method is called after the `doTag` method.
- B. The `setJspBody` method is always called before the `doTag` method.
- C. The `setParent` and `setJspContext` methods are called immediately before the tag attributes are set.
- D. The `JspFragment` of the tag body is invoked by the Container before the tag handler’s `doTag` method is called. This value, a `BodyContent` object, is passed to the tag handler using the `setJspBody` method.
custom tag development

13. Given:

```java
10. public class ExampleTag extends TagSupport {
11.     private String param;
12.     public void setParam(String p) { param = p; }
13.     public int doStartTag() throws JspException {
14.         // insert code here
15.         // more code here
16.     }
17. }
```

Which, inserted at line 14, would be guaranteed to assign the value of the request-scope attribute `param` to the local variable `p`? (Choose all that apply.)

- Option A is invalid because there is no such method.
- Option B is invalid because there is no request instance variable.
- Option C is invalid because an attribute in page scope would be found before checking request scope.
- Option D is invalid because there is no `getPageContext()` method.
- Option F is invalid because `findAttribute()` does not have a scope parameter.

14. Which are valid method calls on a `PageContext` object? (Choose all that apply.)

- Option A and D are invalid because there are no methods with these names.
- Option F is invalid because `findAttribute()` does not have a scope parameter.
mock exam

15 Which is the most efficient JspContext method to call to access an attribute that is known to be in application scope?

A. getPageContext()
B. getAttribute(String)
C. findAttribute(String)
D. getAttribute(String, int)
E. getAttributeScope("key")
F. getAttributeNamesInScope(int)

16 What is the best strategy, when implementing a custom tag, for finding the value of an attribute whose scope is unknown?

A. Check all scopes with a single pageContext.getAttribute(String) call.
B. Check all scopes with a single pageContext.findAttribute(String) call.
C. Check each scope with calls to pageContext.getAttribute(String, int).
D. Call pageContext.getRequestDispatcher().getAttribute(String), then call pageContext.getSession().getAttribute(String), and so on.
E. None of these will work.
custom tag development

Given a tag, `simpleTag`, whose handler is implemented using the Simple tag model and a tag, `complexTag`, whose handler is implemented using the Classic tag model. Both tags are declared to be non-empty in the TLD.

Which JSP code snippets are valid uses of these tags? (Choose all that apply.)

- A. `<my:simpleTag>
   
   `<my:complexTag />
   
   `</my:simpleTag>`

- B. `<my:simpleTag>
   
   `<@ displayText %`
   
   `</my:simpleTag>`

- C. `<my:simpleTag>
   
   `<@ include file="/WEB-INF/web/common/headerMenu.html %`
   
   `</my:simpleTag>`

- D. `<my:simpleTag>
   
   `<my:complexTag>
   
   `<i++;
   
   `</my:complexTag>`
   
   `</my:simpleTag>`

Which are true about the Tag File model? (Choose all that apply.)

- A. Each tag file must have a corresponding entry in a TLD file.
- B. All directives allowed in JSP pages are allowed in Tag Files.
- C. All directives allowed in Tag Files are allowed in JSP pages.
- D. The `<jsp:doBody>` standard action can only be used in Tag Files.
- E. The allowable file extensions for Tag Files are `.tag` and `.tagx`.
- F. For each attribute declared and specified in a Tag File, the container creates a page-scoped attribute with the same name.
mock exam

Which are valid in tag files? (Choose all that apply.)

- A. `<jsp:doBody />`
- B. `<jsp:invoke fragment="frag" />`
- C. `<%@ page import="java.util.Date" %>`
- D. `<%@ variable name="given" variable-class="java.util.Date" %>`
- E. `<%@ attribute name="name" value="blank" type="java.lang.String" %>`

Which returns the enclosing tag when called from within a tag handler class? (Choose all that apply.)

- A. `getParent()`
- B. `getAncestor()`
- C. `findAncestor()`
- D. `getEnclosingTag()`

Given a web application structure:

```
/Web-INF/tags/mytags/tag1.tag
/Web-INF/tags/tag2.tag
/Web-INF/tags/tag3.tag
/tag4.tag
```

Which tags could be used by an appropriate `taglib` directive? (Choose all that apply.)

- A. `tag1.tag`
- B. `tag2.tag`
- C. `tag3.tag`
- D. `tag4.tag`
Chapter 10. When even JSTL is not enough...

---

**custom tag development**

---

1. How can a Classic tag handler instruct the container to ignore the remainder of the JSP that invoked the tag? (Choose all that apply.)
   - A. The `doEndTag()` method should return `Tag.SKIP_BODY`.
   - B. The `doEndTag()` method should return `Tag.SKIP_PAGE`.
   - C. The `doStartTag()` method should return `Tag.SKIP_BODY`.
   - D. The `doStartTag()` method should return `Tag.SKIP_PAGE`.

   - Option A is invalid because this is not a valid return value for `doEndTag()`.
   - Option C is invalid because it only causes the body of the tag to be skipped.
   - Option D is invalid because this is not a valid return value for `doStartTag()`.

2. Which directives and/or standard actions are applicable ONLY within tag files? (Choose all that apply.)
   - A. `tag` (Option A is valid (pg 1-179).
   - B. `page` (Option B is invalid because the page directive is never allowed in a tag file (pg 1-179).
   - C. `jsp:body` (Option C is invalid because the `jsp:body` action can appear in EITHER a tag file or JSP.
   - D. `jsp:doBody` (Option D is valid (pg 1-121).
   - E. `jsp:invoke` (Option E is valid (pg 1-119).
   - F. `taglib` (Option F is invalid because the `taglib` directive can appear in EITHER a tag file or JSP.

### mock answers

#### Given a JSP page:

3. **<my:tag1>**
4. **<my:tag2>**
5. **</my:tag3>**
6. **</my:tag1>**

The tag handler for **my:tag1** is `Tag1Handler` and extends `TagSupport`. The tag handler for **my:tag2** is `Tag2Handler` and extends `SimpleTagSupport`. The tag handler for **my:tag3** is `Tag3Handler` and extends `TagSupport`.

Which is true? (Choose all that apply.)

- **A.** `Tag3Handler` CANNOT access the instance of `Tag1Handler` because Simple tags do NOT support access to the tag parent.

- **B.** Only Classic tags are considered in composing the parent/child tag hierarchy; therefore, `Tag3Handler` may use the `getParent` method only once to gain access to the instance of `Tag1Handler`.

- **C.** `Tag3Handler` may use the `getParent` method twice to gain access to the instance of `Tag1Handler`.

- **D.** Only BodyTag handlers can access the parent/child tag hierarchy; therefore, `Tag3Handler` CANNOT gain access to the instance of `Tag1Handler`.

---

4. Which Simple tag mechanism will tell a JSP page to stop processing?

- **A.** Return `SKIP_PAGE` from the `doTag` method.

- **B.** Return `SKIP_PAGE` from the `doEndTag` method.

- **C.** Throw a `SkipPageException` from the `doTag` method.

- **D.** Throw a `SkipPageException` from the `doEndTag` method.

---

560 chapter 10
Custom tag development

5 Which are true about the Classic tag model? (Choose all that apply.)

A. The Tag interface can only be used to create empty tags.

B. The SKIP_PAGE constant is a valid return value of the doEndTag method.

C. The EVAL_BODY_BUFFERED constant is a valid return value of the doAfterBody method.

D. The Tag interface only provides two values for the return value of the doStartTag method: SKIP_BODY and EVAL_BODY.

E. There are three tag interfaces Tag, IterationTag, and BodyTag, but only two built-in base classes: TagSupport and BodyTagSupport.

6 Which about the findAncestorWithTag method are true? (Choose all that apply.)

A. It requires one parameter: A Class.

B. It is a static method in the TagSupport class.

C. It is a non-static method in the TagSupport class.

D. It is NOT defined by any of the standard JSP tag interfaces.

E. It requires two parameters: A Tag and a Class.

F. It requires one parameter: A String representing the name of the tag to be found.

G. It requires two parameters: A Tag and a String representing the name of the tag to be found.
mock answers

7 Which must be true if you want to use dynamic attributes for a Simple tag handler? (Choose all that apply.)

- Option A is invalid because you can have both static and dynamic attributes in a Simple Tag.

- Option B is correct (pg 1-176, 8.4.1).

- Option C is invalid because tag files may be discovered by the container in several well-known locations. This container feature is optional.

- Option D is invalid because there is no such helper class in the built-in APIs.

- Option E is invalid because you are allowed to use the jsp:attribute action with dynamic attributes.

8 Which is true about tag files? (Choose all that apply.)

- Option A is invalid because tag files must be placed under the WEB-INF/tags directory.

- Option B is correct (pg 1-176, 8.4.1).

- Option C is invalid because tag files may be discovered by the container in several well-known locations. This container feature is optional.

- Option D is invalid because tag files are not allowed to be placed in a JAR file in the WEB-INF/lib directory.
Given:

10. public class BufTag extends BodyTagSupport {
11.   public int doStartTag() throws JspException {
12.     // insert code here
13.   }
14. }

Assume that the tag has been properly configured to allow body content.

Which, if inserted at line 12, would cause the JSP code

\<mytags:mytag\>BodyContent\</mytags:mytag\> to output

BodyContent:

- A. return SKIP_BODY;
- B. return EVAL_BODY_INCLUDE;
- C. return EVAL_BODY_BUFFERED;
- D. return BODY_CONTENT;

Which about doAfterBody() is true? (Choose all that apply.)

- A. doAfterBody() is only called on tags that extend TagSupport.
- B. doAfterBody() is only called on tags that extend IterationTagSupport.
- C. Assuming no exceptions occur, doAfterBody() is always called after doStartTag() for any tag that implements IterationTag.
- D. Assuming no exceptions occur, doAfterBody() is called after doStartTag() for any tag that implements IterationTag and returns SKIP_BODY from doStartTag().
- E. Assuming no exceptions occur, doAfterBody() is called after doStartTag() for any tag that implements IterationTag and returns EVAL_BODY_INCLUDE from doStartTag().
mock answers

11. Given a JSP page:

1. `<%@ taglib prefix="my" uri="/WEB-INF/myTags.tld" %>`
2. `<my:tag1>`
3. `<%-- JSP content --%>`
4. `</my:tag1>`

The tag handler for `my:tag1` is `TagHandler` and extends `TagSupport`.

What happens when the instance of `TagHandler` calls the `getParent` method? (Choose all that apply.)

- A. A `JspException` is thrown.
- B. The null value is returned.
- C. A `NullPointerException` is thrown.
- D. An `IllegalArgumentException` is thrown.

12. Which is true about the lifecycle of a Simple tag? (Choose all that apply.)

- A. The `release` method is called after the `doTag` method.
- B. The `setJspBody` method is always called before the `doTag` method.
- C. The `setParent` and `setJspContext` methods are called immediately before the tag attributes are set.
- D. The `JspFragment` of the tag body is invoked by the Container before the tag handler’s `doTag` method is called. This value, a `BodyContent` object, is passed to the tag handler using the `setJspBody` method.

Option B is the correct answer. The `getParent` method does not throw any exceptions.

Option A is invalid because a Simple tag has no release method.

Option B is invalid because the `setJspBody` is not called if the Simple tag is an empty tag.

Option D is invalid because the fragment is invoked by the `doTag` implementation, NOT before the `doTag` is called.
custom tag development

13. Given:

```java
public class ExampleTag extends TagSupport {
  private String param;
  public void setParam(String p) { param = p; }
  public int doStartTag() throws JspException {
    // insert code here
    // more code here
  }
}
```

Which, inserted at line 14, would be guaranteed to assign the value of the request-scoped attribute `param` to the local variable `p`? (Choose all that apply.)

- Option A is invalid because there is no such method.
- Option B is invalid because there is no request instance variable.
- Option C is invalid because an attribute in page scope would be found before checking request scope.
- Option D is invalid because there is no `getPageContext()` method.
- Option E is invalid because `findAttribute()` does not have a scope parameter.

14. Which are valid method calls on a `PageContext` object? (Choose all that apply.)

- Option A is invalid because there is no method with these names.
- Option B and D are invalid because there are no methods with these names.
- Option F is invalid because `findAttribute()` does not have a scope parameter.
mock answers

Which is the most efficient JspContext method to call to access an attribute that is known to be in application scope?

- Option A is invalid because there is no such method.
- Option B is invalid because this method only looks in page scope.
- Option C is invalid because this method would be less efficient than Option D because it first checks the other three scopes.
- Option D is valid because it checks all scopes in one call.
- Option E is invalid because it would be only the first step in a process that would be less efficient than Option D.
- Option F is invalid because no such method exists.

What is the best strategy, when implementing a custom tag, for finding the value of an attribute whose scope is unknown?

- Option A is invalid because this method only checks the page scope.
- Option B is valid because it checks all scopes in one call.
- Option C and D are invalid because they are less efficient than simply calling findAttribute().
- Option E is invalid because none of these will work.

- Option A is invalid because there is no such method.
- Option B is invalid because this method only looks in page scope.
- Option C is invalid because this method would be less efficient than Option D because it first checks the other three scopes.
- Option D is valid because it checks all scopes in one call.
- Option E is invalid because it would be only the first step in a process that would be less efficient than Option D.
- Option F is invalid because no such method exists.

- Option A is invalid because this method only checks the page scope.
- Option B is valid because it checks all scopes in one call.
- Option C and D are invalid because they are less efficient than simply calling findAttribute().
- Option E is invalid because none of these will work.

- Option A is invalid because there is no such method.
- Option B is invalid because this method only looks in page scope.
- Option C is invalid because this method would be less efficient than Option D because it first checks the other three scopes.
- Option D is valid because it checks all scopes in one call.
- Option E is invalid because it would be only the first step in a process that would be less efficient than Option D.
- Option F is invalid because no such method exists.

- Option A is invalid because this method only checks the page scope.
- Option B is valid because it checks all scopes in one call.
- Option C and D are invalid because they are less efficient than simply calling findAttribute().
- Option E is invalid because none of these will work.
Given a tag, `simpleTag`, whose handler is implemented using the Simple tag model and a tag, `complexTag`, whose handler is implemented using the Classic tag model. Both tags are declared to be non-empty in the TLD.

Which JSP code snippets are valid uses of these tags? (Choose all that apply.)

- Option A is correct; a Simple tag may include a Complex tag in the body as long as that tag contains no scripting code.
- Option B is invalid because simple tags cannot have a body that includes a JSP expression tag.
- Option C is correct because the include directive is processed before the body of the simple tag is converted into a JspFragment; however, the included content must also be non-scripting (which is why this example includes an HTML segment).
- Option D is not invalid because of the complex tag usage (as in Option A), but because the complex tag body has scripting code in it.

Which are true about the Tag File model? (Choose all that apply.)

- Option A is invalid because tag files need only to be placed in the appropriate location in order to be used.
- Option B is invalid because the page directive is not available in Tag Files.
- Option C is invalid because the tag attribute, and variable directives are not available in JSP pages.
- Option D is correct because the `<jsp:doBody>` standard action can only be used in Tag Files.
- Option E is correct because the container creates a page-scoped attribute with the same name.
- Option F is correct because each attribute declared and specified in a Tag File.
mock answers

19 Which are valid in tag files? (Choose all that apply.)
✓ A. `<jsp:doBody />`
✓ B. `<jsp:invoke fragment="frag" />`
✓ C. `<%@ page import="java.util.Date" %>`
✓ D. `<%@ variable name="date" variable-class="java.util.Date" %>`
✓ E. `<%@ attribute name="name" values="blank" type="java.lang.String" %>`

- Option C is invalid because the page directive is not valid in tag files.
- Option E is invalid because there is no value attribute defined for the attribute directive.

20 Which returns the enclosing tag when called from within a tag handler class? (Choose all that apply.)
✓ A. `getParent()`
✓ B. `getAncestor()`
✓ C. `findAncestor()`
✓ D. `getEnclosingTag()`

- Option A is incorrect; it is the only one of the methods shown that exists.

21 Given a web application structure:
```
/WEB-INF/tags/mytags/tag1.tag
/WEB-INF/tags/tag2.tag
/WEB-INF/tags/tag3.tag
/tag4.tag
```
Which tags could be used by an appropriate `taglib` directive? (Choose all that apply.)
✓ A. `tag1.tag`
✓ B. `tag2.tag`
✓ C. `tag3.tag`
✗ D. `tag4.tag`

- Options C and D are invalid because tag files must be placed under the `/WEB-INF/tags` directory or a subdirectory of `/WEB-INF/tags`.

568 chapter 10
Finally, your web app is ready for prime time. Your pages are polished, your code is tested and tuned, and your deadline was two weeks ago. But where does everything go? So many directories, so many rules. What do you name your directories? What does the client think they’re named? What does the client actually request, and how does the Container know where to look? How do you make certain that you don’t accidentally leave out a directory when you move the whole web app to a different machine? What happens if the client requests a directory instead of a specific file? How do you configure the DD for error pages, welcome files, and MIME types? It’s not as bad as it sounds...
Objectives

Chapter 11. Deploying your web app

Web Application Deployment

2.1 Construct the file and directory structure of a web application that may contain (a) static content, (b) JSP pages, (c) servlet classes, (d) the deployment descriptor, (e) tag libraries, (f) JAR files, and (g) Java class files. Describe how to protect resource files from HTTP access.

2.2 Describe the purpose and semantics for each of the following deployment descriptor elements: error-page, init-param, mime-mapping, servlet, servlet-class, servlet-mapping, servlet-name, and welcome-file.

2.3 Construct the correct structure for each of the following deployment descriptor elements: error-page, init-param, mime-mapping, servlet, servlet-class, servlet-name, and welcome-file.

2.4 Explain the purpose of a WAR file and describe the contents of a WAR file and how one may be constructed.

6.3 Write a JSP Document (XML-based syntax) that uses the correct syntax.

Coverage Notes:

This objective has been covered throughout the book in earlier chapters, so most of the content in this chapter related to this objective is either for review or to look at something in a little more detail.

Objectives 2.2 and 2.3 focus mainly on picky XML tag details related to the Deployment Descriptor. While this is probably the least fun part of the book (and the exam), most of this content is easy to understand and it's just a matter of memorizing the tags. There is one tricky part, though, and we'll spend most of our time on it—servlet mapping.

We decided to stick this objective into this chapter for two reasons: 1) most of this chapter has to do with XML, and 2) we didn't want to add anything else into the JSP chapters. We decided it was better for you to concentrate more on the syntax and behavior of all the other parts of JSP, rather than also worrying about the XML versions of everything. But now that you're an expert... we figure you can handle it.

570 chapter 11
The Joy of Deployment

We’ve covered most of the fun stuff, but now it’s time for a more detailed look at deployment.

In this chapter, you need to think about three main issues:

1. **Where do YOU put things in the web app?**
   - Where do you put static resources? JSP pages? Servlet class files? JavaBean class files? Listener class files? Tag files? Tag handler classes? TLDs? JAR files? The web.xml DD? Where do you put things that you don’t want the Container to serve? (In other words, which parts of the web app are protected from direct client access?) Where do you put “welcome” files?

2. **Where will the CONTAINER look for things in the web app?**
   - Where will the Container look when the client requests an HTML page? A JSP page? A servlet? Something that doesn’t exist as an actual file (like, BeerTest.do)? Where will the Container look for tag handler classes? Where will the Container look for TLDs? Tag Files? JAR files? The Deployment Descriptor? Other classes my servlets depend on? Where does the Container look for “welcome” files? (Obviously, once you know all of this, then everything in number “1” becomes a no-brainer.)

3. **How does the CLIENT request things in the web app?**
   - What does the client type into the browser to access an HTML page? A JSP page? A servlet? Something that doesn’t actually exist as a file? In which places can the client make a direct request, and in which places is the client restricted from direct access to a resource? What happens if the client types in a path to only a directory, not a specific file?
What goes where in a web app

In several chapters of this book, we’ve looked at the locations in which the various files must be placed. In the chapter on custom tags, for example, you saw that Tag Files must be deployed in /WEB-INF/tags or a subdirectory, or in a JAR file under /META-INF/tags or a subdirectory. If you put a Tag File anywhere else, the Container will either ignore it or treat it as static content ready to be served.

The Servlet and JSP spec have a lot of picky rules about where things go, and you really do need to know most of them. Since we’ve already covered most of this in one way or another, we use these first few pages as a test of your memory and understanding. Don’t skip it! Treat these next few pages as practice exam questions!

Q: Why should I have to know where everything goes... isn't that what deployment tools are for? Or even an ANT build script?

A: If you’re lucky, you’re using a J2EE deployment tool that lets you point and click your way through a series of wizard screens. Then your Container uses that info to build the XML Deployment Descriptor (web.xml), build out the necessary directory structures, and copy your files into the appropriate locations. But even if you are lucky, don’t you think you need to know what the tool is doing? You might need to tweak what the tool does. You might need to troubleshoot. You might switch to a different vendor that doesn’t have an automated deployment tool.

A lot of developers use a build tool like ANT, but even then, you still need to tell ANT what to do.

Q: But I just got an ANT build script off the internet, and it’s already configured to do it all for me.

A: Again, that’s great—but you still need to know what’s really happening. If you’re completely at the mercy of your tool, you’re in trouble if something goes wrong. Knowing how to structure a web app is like knowing how to change a tire—maybe you’ll never need to do it yourself, but if it’s 3:00 AM and you’re in the middle of nowhere, isn’t it nice to know you can?

And for those of you taking the exam, well, you don’t have a choice. Virtually everything in this chapter is covered on the exam.
**Name the directories**

Write the correct directory names in, given the files shown within those directories. Everything in here has been covered in an earlier chapter, but don’t worry if you haven’t completely memorized them all yet. This is the chapter where you have to *burn it in*. 

![Diagram of directory structure](image-url)
exercise on deployment

Draw the directory and file structure

Look at the following web app description and draw a directory structure that supports that web app. Be sure to include the files too. There may be more than one way to structure this; we recommend using the simplest (i.e. least number of directories) to organize it.

Application name: Dating

Static content and JSPs: welcome.html, signup.jsp, search.jsp

Servlets: dating.Enroll.class, dating.Search.class

Custom tag handler class: tagClasses.TagOne.class

TLD: DatingTags.tld

JavaBeans: dating.Client.class

DD: web.xml

Support JAR files: DatingJar.jar
BE the Container

What's wrong with this deployment?
There are several things here that do not follow the Servlet or JSP specification for where they should be placed. Assume that all files have the correct names and extensions.

List everything that's wrong with this picture:

web app deployment

you are here 575
exercise on deployment

Name the directories

To deploy a web app successfully, you MUST follow this structure. WEB-INF must be immediately under the application context (“MyTestApp” in this example). The “classes” directory must be immediately inside “WEB-INF”. The package structure for the classes must be immediately inside “classes”. The “lib” directory must be immediately inside “WEB-INF”, and the JAR file must be immediately inside “lib”. The “META-INF” directory must be immediately inside the JAR, and TLD files in a JAR must be somewhere under “META-INF” (they can be in any subdirectory, and “TLDs” is not required as a directory name). TLDs that are NOT in a JAR must be somewhere under “WEB-INF”. Tag Files (files with a .tag or .tag extension) must be somewhere under “WEB-INF/tags” (unless they’re deployed in a JAR, in which case they must be somewhere under “META-INF/tags”).
**web app deployment**

**Draw the directory and file structure**

The only things that could be different in this picture are 1) the static content and JSPs could be in a subdirectory under “Dating”, or hidden under “WEB-INF” and 2) the DatingTags.tld could be in a subdirectory of WEB-INF.

**Application name:** Dating

**Static content and JSPs:** welcome.html, signup.jsp, search.jsp

**Servlets:** dating.Enroll class, dating.Search class

**Custom tag handler class:** tagClasses.TagOne class

**TLD:** DatingTags.tld

**JavaBeans class:** dating.Client class

**DD:** web.xml

**Support JAR files:** DatingJar.jar

---

**Chapter 11. Deploying your web app**

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: O'Reilly

exercise on directories and files

Several things are wrong with this picture!

- web.xml must be inside "WEB-INF".
- Tag Files (.tag) must be somewhere under "WEB-INF/tags".
- The "classes" directory must NOT be under "lib", it must be under "WEB-INF".
- The "lib" directory is in the right place (under "WEB-INF").

OK (assuming the "classes" directory is moved out of "lib" and placed directly under "WEB-INF").
Chapter 11. Deploying your web app

What she really wants is a **WAR file**

The directory structure of a web app is intense. And everything has to be in exactly the right place. Moving a web app can hurt.

But there’s a solution, called a WAR file, which stands for WebARchive. And if that sounds suspiciously like a JAR file (Java ARchive), that’s because a WAR is a JAR. A JAR with a .war extension instead of .jar.

**web app deployment**
deploying a web app in a WAR

WAR files

A WAR file is simply a snapshot of your web app structure, in a nice portable, compressed form (it’s really just a JAR file). You jar up your entire web app structure (minus the web app context directory—the one that’s above WEB-INF), and give it a .war extension. But that does leave one problem—if you don’t include the specific web app directory (BeerApp, for example), how does the Container know the name/context of this web app?

That depends on your Container. In Tomcat, the name of the WAR file becomes the web app name! Imagine you deploy BeerApp as a normal directory structure under tomcat/webapps/BeerApp. To deploy it as a WAR file, you jar up everything in the BeerApp directory (but not the BeerApp directory itself), then name the resulting JAR file BeerApp.war. Then you drop the BeerApp.war file into the tomcat/webapps directory. That’s it. Tomcat unpacks the WAR file, and creates the web app context directory using the name of the WAR file. But again, your Container may handle WAR deployment and naming differently. What matters to us here is what’s required by the spec, and the answer is—it makes almost no difference whether the app is deployed in or out of a WAR! In other words, you still need WEB-INF, web.xml, etc. Everything on the previous pages applies.

Almost everything. There is one thing you can do when you use a WAR file that you can’t do when you deploy without one—declare library dependencies.

In a WAR file, you can declare library dependencies in the META-INF/MANIFEST.MF file, which gives you a deploy-time check for whether the Container can find the packages and classes your app depends on. That means you don’t have to wait until a resource is requested before the whole thing blows up because the Container doesn’t have a particular class in its classpath that the requested resource needs.

Don’t be fooled by questions about WAR files... the rules don’t change!

Quick quiz: do you still need a file named web.xml if you deploy as a WAR? Of course. Do you still need a WEB-INF directory if you deploy as a WAR? Of course. Do you still need to put classes in a “classes” directory under “WEB-INF”? Of course. You get the idea. The rules don’t change just because you put your app in a WAR! The only significant difference is that a WAR file will have a “META-INF” directory under the web app context (a peer to the “WEB-INF” directory).
What a deployed WAR file looks like

When you deploy a web app into Tomcat by putting the WAR file into the webapps directory, Tomcat unpacks it, creates the context directory (MyTestApp in this example), and the only new thing you’ll see is the META-INF directory (with the MANIFEST.MF file inside). You will probably never put anything into the META-INF directory yourself, so you’ll probably never care whether your app is deployed as a WAR unless you do need to specify library dependencies in the MANIFEST.MF file.
Making static content and JSPs directly accessible

When you deploy static HTML and JSPs, you can choose whether to make them directly accessible from outside the web app. By directly accessible, we mean that a client can enter the path to the resource into his browser, and the server will return the resource. But you can prevent direct access by putting files under WEB-INF or, if you're deploying as a WAR file, under META-INF.

Valid request

http://www.wickedlysmart.com/MyTestApp/register/signUp.jsp

Invalid request (produces "404 Not Found" error)

http://www.wickedlysmart.com/MyTestApp WEB-INF/process.jsp

Nothing under WEB-INF or META-INF is directly accessible.

If the server gets a client request for anything under WEB-INF or META-INF, the Container MUST respond with a 404 NOT FOUND error!
Q: If you can’t serve content from WEB-INF or META-INF, what’s the point of putting pages there??!

A: Think about that. You have Java classes and class members with package-level (default) access, right? These are classes and members not available to the “public,” but meant for internal use by other classes and members that are publicly exposed. It’s the same way for these non-accessible static content and JSPs. By putting them under WEB-INF (or, with a WAR file, META-INF), you’re protecting them from any direct access, while still allowing other parts of the web app to use them.

You might, for example, want to forward to or include a file while making sure that no client can directly request it. Chances are, if you want to protect a resource from direct access, you’ll use WEB-INF and not META-INF, but for the exam, you have to know that the rules apply to both.

Q: What about a META-INF directory inside a JAR file inside WEB-INF/lib? Does that have the same protection as META-INF inside the WAR file?

A: Well…yes. But the fact that the content is in META-INF is not the point. In this case, you’re talking about a JAR file inside the lib directory inside WEB-INF. And anything in WEB-INF is protected from direct access! So, it doesn’t matter where under WEB-INF the content is, it’s still protected. When we say that META-INF is protected, we’re really talking about META-INF inside a WAR file, because the META-INF inside WEB-INF/lib JAR files is always protected anyway by virtue of being under WEB-INF.

Q: On an earlier page you mentioned putting library dependencies in the META-INF/MANIFEST.MF file. Are you required to do that? Isn’t everything in the WEB-INF/lib/jar files and the WEB-INF/classes directory automatically on the classpath for this application?

A: Yes, classes you deploy in with the web app, by using the WEB-INF/classes directory or a JAR in WEB-INF/lib, are available and you don’t have to do or say anything. They just work. But…you might have a Container with optional packages on its classpath, and maybe you’re depending on some of those packages. Or maybe you’re depending on a particular version of a library! The MANIFEST.MF file gives you a place to tell the Container about the optional libraries you must have access to. If the Container can’t provide them, it won’t let you successfully deploy the application. Which is a lot better than if you deploy and then find out later, at request time, when you get some horrible (or worse—subtle) runtime error.

Q: How does the Container access the content inside JAR files in WEB-INF/lib?

A: The Container automatically puts the JAR file into its classpath, so classes for servlets, listeners, beans, etc. are available exactly as they are if you put the classes (in their correct package directory structure, of course) within the WEB-INF/classes directory. In other words, it doesn’t matter whether the classes are in or out of a JAR as long as they’re in the right locations.

Keep in mind, though, that the Container will always look for classes in the WEB-INF/classes directory before it looks inside JAR files in WEB-INF/lib.

Q: OK, that explains class files, but what about other kinds of files? What if I need to access a text file that’s deployed in a JAR in WEB-INF/lib?

A: This is different. If your web app code needs direct access to a resource (text file, JPEG, etc.) that’s inside a JAR, you need to use the getResource() or getResourceAsStream() methods of the classloader—this is just plain old J2SE, not specific to servlets.

Now, you might recognize those two methods (getResource() and getResourceAsStream()), because they exist also in the ServletContext API. The difference is, the methods inside ServletContext work only for resources within the web app that are not deployed within a JAR file. (For the exam, you need to know that you can use the standard J2SE mechanism for getting resources from JAR files, but you do not need to know any details.)
How servlet mapping REALLY works

You’ve seen examples of servlet mapping in the Deployment Descriptors we’ve used in earlier chapters, beginning with the tutorial.

Every servlet mapping has two parts—the <servlet> element and the <servlet-mapping> element. The <servlet> defines a servlet name and class, and the <servlet-mapping> defines the URL pattern that maps to a servlet name defined somewhere else in the DD.

```
<web-app xmlns="http://java.sun.com/xml/ns/j2ee"
         xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
         xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd"
         version="2.4">

  <servlet>
    <servlet-name>Beer</servlet-name>
    <servlet-class>com.example.BeerSelect</servlet-class>
  </servlet>

  <servlet-mapping>
    <servlet-name>Beer</servlet-name>
    <url-pattern>/Beer/SelectBeer.do</url-pattern>
  </servlet-mapping>

</web-app>
```

When a request comes in that looks like this, the Container finds the matching <servlet-name> in a <servlet> element, to know which class is responsible for handling the request. And I see that there is a servlet with that <servlet-name>, "Beer", and it tells me which servlet class will handle this request.

If the client request comes in for /Beer/SelectBeer.do, that refers to the servlet named "Beer".

This name is mainly for use in other parts of the DD. It is NOT something the client will know about.
Chapter 11. Deploying your web app

But I don’t see a directory named “Beer” and there’s no file named SelectBeer.do.

This is the context/root of this particular web app.
This exists ONLY in the DD!

http://www.wickedlysmart.com/AdviceApp/Beer/BeerSelect.do

The ACTUAL (physical) directory structure

webapps
    AdviceApp
        WEB-INF
            classes
                web.xml
                BeerSelectClass
            com
                example

The VIRTUAL (logical) directory structure

webapps
    AdviceApp
        WEB-INF
            classes
                BeerSelectClass
            com
                example

This does not really exist!

This exists ONLY in the DD!

This is the context/root of this particular web app.

This is the servlet that handles the /Beer/BeerSelect.do request.

Redistribution or other use that violates the fair use privilege under U.S. copyright laws (see 17 USC107) or that otherwise violates the Safari Terms of Service is strictly prohibited.
**virtual vs. logical**

**Servlet mappings can be “fake”**

The URL pattern you put into a servlet mapping can be completely made-up. Imaginary. Fake. Just a logical name you want to give clients. Clients who have no business knowing anything about the real physical structure of your web app.

With servlet mappings, you have two structures to organize: the real physical directory and file structure in which your web app resources live, and the virtual/logical structure.

**The THREE types of <url-pattern> elements**

1. **EXACT match**
   
   `<url-pattern>/Beer/SelectBeer.do</url-pattern>`
   
   Must begin with a slash (/). Can have an extension, but it's not required.

2. **DIRECTORY match**
   
   `<url-pattern>/Beer/*</url-pattern>`
   
   Must begin with a slash (/). Always ends with a slash/asterisk (/*).
   
   This can be a virtual OR real directory.

3. **EXTENSION match**
   
   `<url-pattern>*.do</url-pattern>`
   
   Must begin with an asterisk (*) (NEVER with a slash). After the asterisk, it MUST have a dot extension (.do, .jsp, etc.).

The virtual/logical structure exists simply because you say it exists!

The URL patterns in the DD don't map to anything except other <servlet-name> elements in the DD.

The <servlet-name> elements are the key to servlet mapping—they match a request <url-pattern> to an actual servlet class.

Key point: clients request servlets by <url-pattern>, not by <servlet-name> or <servlet-class>!
Chapter 11. Deploying your web app

Key rules about servlet mappings

1) The Container looks for matches in the order shown on the opposite page. In other words, it looks first for an exact match. If it can’t find an exact match, it looks for a directory match. If it can’t find a directory match, it looks for an extension match.

2) If a request matches more than one directory <url-pattern>, the Container chooses the longest mapping. In other words, a request for /foo/bar/myStuff.do will map to the <url-pattern> /foo/bar/* even though it also matches the <url-pattern> /foo/* . The most specific match always wins.
exercise on servlet mapping

BE the Container
Answers

Mappings:

```
<servlet>
  <servlet-name>One</servlet-name>
  <servlet-class>foo.DeployTestOne</servlet-class>
</servlet>

<servlet>
  <servlet-name>Two</servlet-name>
  <servlet-class>foo.DeployTestTwo</servlet-class>
</servlet>

<servlet>
  <servlet-name>Three</servlet-name>
  <servlet-class>foo.DeployTestThree</servlet-class>
</servlet>

<servlet>
  <servlet-name>One</servlet-name>
  <servlet-class>foo.DeployTestOne</servlet-class>
  <url-pattern>*.do</url-pattern>
</servlet>

<servlet>
  <servlet-name>Two</servlet-name>
  <servlet-class>foo.DeployTestTwo</servlet-class>
  <url-pattern>/fooStuff/bar</url-pattern>
</servlet>

<servlet>
  <servlet-name>Three</servlet-name>
  <servlet-class>foo.DeployTestThree</servlet-class>
  <url-pattern>/fooStuff/</url-pattern>
</servlet>
```

Requests:

```
http://localhost:8080/MapTest/blue.do
Container choice: DeployTestOne
  (matched the *.do extension pattern)

http://localhost:8080/MapTest/fooStuff/bar
Container choice: DeployTestTwo
  (exact match with /fooStuff/bar pattern)

http://localhost:8080/MapTest/fooStuff/bar/blue.do
Container choice: DeployTestThree
  (matched the /fooStuff/ directory pattern)

http://localhost:8080/MapTest/fooStuff/blue.do
Container choice: DeployTestOne
  (matched the *.do extension pattern)

http://localhost:8080/MapTest/fooStuff
Container choice: DeployTestThree
  (matched the /fooStuff/ directory pattern)

http://localhost:8080/MapTest/fooStuff/bar/foो
Container choice: DeployTestThree
  (matched the /fooStuff/ directory pattern)

http://localhost:8080/MapTest/foो/blue.do
Container choice: DeployTestOne
  (matched the *.do extension pattern)

http://localhost:8080/MapTest/foो/foो
Container choice: DeployTestThree
  (matched the /fooStuff/ directory pattern)

http://localhost:8080/MapTest/foो/foो/fo
Container choice: DeployTestThree
  (matched the /fooStuff/ directory pattern)
```

Answers to the exercise on the opposite page:

```
GET /fooStuff/bar

GET /fooStuff/bar/blue.do

HEAD /fooStuff/bar

PUT /fooStuff/bar

POST /fooStuff/bar

DELETE /fooStuff/bar
```

588 chapter 11
Subtle issues...

Just to make sure you understand servlet mappings, here’s one more little example. Don’t skim—look closely at both the mapping and the requests. (In this mini “Be the Container”, the answers are at the bottom of the opposite page, so don’t peek.)

BE the Container
Which servlet will the Container choose?

Mappings in the DD

```xml
<servlet>
  <servlet-name>Two</servlet-name>
  <servlet-class>foo.DeployTestTwo</servlet-class>
</servlet>
<servlet-mapping>
  <servlet-name>Two</servlet-name>
  <url-pattern>/fooStuff/bar</url-pattern>
</servlet-mapping>
<servlet>
  <servlet-name>Four</servlet-name>
  <servlet-class>foo.DeployTestFour</servlet-class>
</servlet>
<servlet-mapping>
  <servlet-name>Four</servlet-name>
  <url-pattern>/fooStuff/bar/*</url-pattern>
</servlet-mapping>
```

Requests:

   Container choice:

   Container choice:`
**welcome files**

**Configuring welcome files in the DD**

You already know that if you type in the name of a web site and you don’t specify a specific file, you (usually) still get something back. Entering `http://www.oreilly.com` into your browser takes you to the O'Reilly web site, and even though you didn’t name a specific resource (like “home.html”, for example), you still get a default page.

You can configure your server to define a default page for the entire site, but we’re concerned here with default (also known as “welcome”) pages for individual web apps. You configure welcome pages in the DD, and that DD determines what the Container chooses when the client enters a partial URL—a URL that includes a directory, for example, but not a specific resource in the directory.

In other words, what happens if the client request comes in for:

```
http://www.wickedlysmart.com/foo/bar
```

and “bar” is simply a directory, and you don’t have a specific servlet mapped to this URL pattern. What will the client see?

**In the DD:**

```xml
<web-app ...>
  <welcome-file-list>
    <welcome-file>index.html</welcome-file>
    <welcome-file>default.jsp</welcome-file>
  </welcome-file-list>
</web-app>
```

They must NOT start or end with a slash!

Imagine you have a web app where several different directories have their own default HTML page, named “index.html”. But some directories use a “default.jsp” instead. It would be a huge pain if you had to specify a specific default page or JSP for each directory that needs one. Instead, you specify a list, in order, of the pages you want the Container to look for in whatever directory the partial request is for. In other words, no matter which directory is requested, the Container always looks through the same list—the one and only `<welcome-file-list>`.

The Container will pick the first match it finds, starting with the first welcome file listed in the `<welcome-file-list>`.

Chapter 11. Deploying your web app
exercise on welcome files

BE the Container

Answers

The DD:

```
<welcome-file-list>
  <welcome-file>index.html</welcome-file>
  <welcome-file>default.jsp</welcome-file>
</welcome-file-list>
```

Directory structure:

```
webapps
  MyTestApp
    search
    registration
      index.html
      default.jsp
      newMember
        index.html
        foo.txt
```

Requests:

- http://localhost:8080/MyTestApp/
  - Container choice: MyTestApp/index.html
- http://localhost:8080/MyTestApp/registration/
  - Container choice: MyTestApp/registration/index.html
- http://localhost:8080/MyTestApp/search
  - Container choice: MyTestApp/search/default.jsp
    (If there HAD been both a default.jsp and an index.html in the “search” directory, the Container would have chosen the “index.html” file, since it is listed first in the DD.)
- http://localhost:8080/MyTestApp/registration/newMember/
  - Container choice: The behavior is vendor-specific. Tomcat shows a directory listing for the newMember directory (which shows “foo.txt”). Another Container might show a 404 Not Found error.
# How the Container chooses a welcome file

1. **Client requests:** http://www.wickedlysmart.com/MyTestApp/search

   ![Diagram](container.png)

2. **Container looks in the DD for a servlet mapping, and doesn’t find a match. Next, the Container looks in the `welcome-file-list` and sees "index.html" at the top.**

   ![Diagram](container.png)

3. **Container looks in the `/MyTestApp/search` directory for an "index.html" file, but does not find one.**

   ![Diagram](container.png)

4. **Container looks at the next `welcome-file` in the `welcome-file-list` in the DD, and sees "default.jsp".**

   ![Diagram](container.png)

5. **Container looks in the `/MyTestApp/search` directory for a "default.jsp" file, finds one, and serves its response to the client.**

   ![Diagram](container.png)

---

**You are here**
error pages

**Configuring error pages in the DD**

Sure, you want to be friendly when the user doesn’t know the exact resource to ask for when they get to your site or web app, so you specify default/welcome files. But you also want to be friendly when *things go wrong*. We already looked at this in the chapter on Using Custom Tags, so this is just a review.

**Declaring a catch-all error page**

This applies to everything in your web app—not just JSPs.

```xml
<error-page>
    <exception-type>java.lang.Throwable</exception-type>
    <location>/errorPage.jsp</location>
</error-page>
```

(FYI: you can override this in individual JSPs by adding a page directive with an `errorPage` attribute.)

**Declaring an error page for a more explicit exception**

This configures an error page that’s called only when there’s an `ArithmeticException`. If you have both this declaration and the catch-all above, then any exception other than `ArithmeticException` will still end up at the “errorPage.jsp”.

```xml
<error-page>
    <exception-type>java.lang.ArithmeticException</exception-type>
    <location>/arithmeticError.jsp</location>
</error-page>
```

**Declaring an error page based on an HTTP status code**

This configures an error page that’s called only when the status code for the response is “404” (file not found).

```xml
<error-page>
    <error-code>404</error-code>
    <location>/notFoundError.jsp</location>
</error-page>
```

Chapter 11. Deploying your web app

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: O'Reilly
Prepared for Stephen Goss, Safari ID: stephengoss@gmx.net

Print Publication Date: 8/1/2004
User number: 747221 Copyright 2007, Safari Books Online, LLC.

This PDF is exclusively for your use in accordance with the Safari Terms of Service. No part of it may be reproduced or transmitted in any form by any means without the prior written permission for reprints and excerpts from the publisher. Redistribution or other use that violates the fair use privilege under U.S. copyright laws (see 17 USC107) or that otherwise violates the Safari Terms of Service is strictly prohibited.
Q: What are you allowed to declare as an exception type in `<exception-type>`?

A: Anything that’s a Throwable, so that includes java.lang.Error, runtime exceptions, and any checked exception (as long as the checked exception class is on the Container’s classpath, of course).

Q: Speaking of error handling, can you programmatically generate error codes yourself?

A: Yes, you can. You can invoke the `sendError()` method on the `HttpServletResponse`, and it’ll tell the Container to generate that error just as if the Container generated the error on its own. And if you’ve configured an error page to be sent to the client based on that error code, that’s what the client will get. And by the way, “error” codes are also known as “status” codes, so if you see either one, they mean the same thing—HTTP codes for errors.

Q: How about an example of generating your own error code?

A: OK, here’s an example:

```java
response.sendError(HttpServletResponse.SC_FORBIDDEN);
```

which is the same as:

```java
response.sendError(403);
```

If you look in the `HttpServletResponse` interface, you’ll see a bunch of constants defined for the common HTTP error/status codes. Keep in mind that for the exam, you don’t need to memorize the status codes! It’s enough to simply know that you can generate error codes, that the method is `response.sendError()`, and that in terms of the error pages you’ve defined in the O/D, or any other error-handling you do in your JSPs, there’s no difference between Container-generated and programmer-generated HTTP errors. A 403 is a 403 regardless of WHO sends the error. Oh yeah, there’s also an overloaded two-argument version of `sendError()` that takes an int and a String message.
load-on-startup configuration

Configuring servlet initialization in the DD

You already know that servlets, by default, are initialized at first request. That means the first client suffers the pain of class loading, instantiation, and initialization (setting a ServletContext, invoking listeners, etc.), before the Container can do what it normally does—allocate a thread and invoke the servlet's service() method.

If you want servlets to be loaded at deploy time (or at server restart time) rather than on first request, use the <load-on-startup> element in the DD. Any value greater than zero for <load-on-startup> tells the Container to initialize the servlet when the app is deployed (or any time the server restarts).

If you have multiple servlets that you want preloaded, and you want to control the order in which they're initialized, the value of <load-on-startup> determines the order. In other words, any value greater than zero means load early, but the order in which servlets are loaded is based on the value of the different <load-on-startup> elements. If you have two or more servlets with the same value, the Container loads them in the order in which the servlets are declared in the DD.

In the DD

```xml
<servlet>
  <servlet-name>KathyOne</servlet-name>
  <servlet-class>Foo.DeployTestOne</servlet-class>
  <load-on-startup>1</load-on-startup>
</servlet>
```

Q: Wouldn't you ALWAYS want to do this? Shouldn't everyone just use <load-on-startup>-1<load-on-startup> by default?

A: To answer that question, you ask yourself, “How many servlets do I have in my app, and how likely is it that they'll all be used?” And you'll also need to ask, “How long does it take each servlet to load?” Some servlets are rarely used, so you might want to conserve resources by not loading the rarely-used servlets in advance. But some servlets take so painfully long to initialize (like the Struts ActionServlet), that you don't want even a single client to experience that much latency. So, only you can decide, and you'll probably decide on a servlet-by-servlet basis, evaluating both the pain level and likelihood of use for each servlet.

596  chapter 11
Making an XML-compliant JSP: a JSP Document

This topic didn’t fit well anywhere else, so we decided to stick it in this chapter since we’re talking about XML so much. The exam doesn’t require you to be an XML expert, but you do have to know two things: the syntax for the key DD elements, and the basics of making what’s known as a JSP Document. (As opposed to what? If a normal JSP isn’t a document, what is it?) That’s what you’re asking, right? Think of it this way—a normal JSP is a page, unless it’s written with the XML alternatives to normal JSP syntax, in which case it becomes a document.

All it means is that there are really two types of syntax you can use to make a JSP. The text in grey is the same across both types of syntax.

<table>
<thead>
<tr>
<th>Normal JSP page syntax</th>
<th>JSP document syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Directives</strong>&lt;br&gt;(except taglib)</td>
<td>&lt;jsp:directive.page import=&quot;java.util.*&quot;/&gt;</td>
</tr>
<tr>
<td>Declaration</td>
<td><a href="">jsp:declaration</a></td>
</tr>
<tr>
<td>Scriptlet</td>
<td><a href="">jsp:scriptlet</a></td>
</tr>
<tr>
<td>Text</td>
<td><a href="">jsp:text</a></td>
</tr>
<tr>
<td>Scripting Expression</td>
<td><a href="">jsp:expression</a></td>
</tr>
</tbody>
</table>

This is all the exam covers on JSP Documents.

We aren’t going to say any more about it because writing XML-compliant JSP documents is probably not something you’ll do. The XML syntax is used mainly by tools, and the table above just shows you how the tool would transform your normal JSP syntax into an XML document. There is more you have to know if you write this by hand—the whole document, for example, must be enclosed in a `<jsp:root>` tag (which includes some other stuff), and the taglib directives go inside the `<jsp:root>` opening tag, rather than as a `<jsp:directive>`.

But everything that might be on the exam is in the table above. So relax.
configuring EJB references

Memorizing the EJB-related DD tags

This exam is about web components, not business components (although in the Patterns chapter, you'll see a few things about business components). But if you're deploying a J2EE app, complete with Enterprise JavaBeans (EJBs) in the business tier, some of your web components will probably need to lookup and access the enterprise beans. If you're deploying an app in a full J2EE-compliant Container (one that has an EJB Container as well), you can define references to EJBs in the DD. You don't have to know anything about EJBs for this exam, other than what you declare in the DD, so we won't waste your time explaining it here.⁹

Reference to a local bean

```
<ejb-local-ref>
  <ejb-ref-name>ejb/LocalCustomer</ejb-ref-name>
  <ejb-ref-type>Entity</ejb-ref-type>
  <local-home>com.wickedlysmart.CustomerHome</local-home>
  <local>com.wickedlysmart.Customer</local>
</ejb-local-ref>
```

A LOCAL bean means the client (in this case, a servlet) and the bean must be running in the same JVM.

Reference to a remote bean

```
<ejb-ref>
  <ejb-ref-name>ejb/LocalCustomer</ejb-ref-name>
  <ejb-ref-type>Entity</ejb-ref-type>
  <home>com.wickedlysmart.CustomerHome</home>
  <remote>com.wickedlysmart.Customer</remote>
</ejb-ref>
```

A REMOTE bean means the client (in this case, a servlet) and the bean can be running in different JVMs (possibly on different physical machines as well).

* But if you're interested in EJB, there's this really good book...
Chapter 11. Deploying your web app

The LOCAL and REMOTE tags are inconsistent!

Both the local and remote bean DD tags have two elements that are the same:
The `<ejb-ref-name>` that lists the logical lookup name you’ll use in code to perform a JNDI lookup on an enterprise bean’s home interface. (Don’t worry if you haven’t used EJBs before and don’t know what that last sentence means—you don’t need EJB knowledge for this exam.) The `<ejb-ref-type>` describes whether this is an Entity or Session bean. Though two elements, the lookup name and the bean type, don’t depend on whether the bean is local (running in the same JVM as the web component), or remote (potentially running in a different JVM).

But... look at the other elements starting with the outer tags: `<ejb-local-ref>` and `<ejb-ref>`. You might be tempted to think that it’s:

- `<ejb-local-ref>` → yes
- `<ejb-remote-ref>` ← Wrong!!

But NO! For remote beans, it’s just:

- `<ejb-ref>` ← Right! There’s no “remote” in the tag.

In other words, the local reference says it’s local, but the remote reference does NOT include the word “remote” in its tag element name. Why? Because at the time `<ejb-ref>` was first defined, there was no such thing as “local” EJBs. Since ALL enterprise beans were “remote”, there was no need to differentiate between local and remote, so no need to put “remote” in the name of the tag. This also explains the OTHER tag naming inconsistency—the name of the tag for the bean’s home interface. A local bean uses:

- `<local-home>` ← Yes
- `<remote-home>` ← No!

But a remote bean does NOT use:

- `<remote-home>` ← Wrong!!

For remote beans, it’s just:

- `<home>`
configuring the `<env-entry>`

Memorizing the JNDI `<env-entry>` DD tag

If you’re familiar with EJB and/or JNDI, this will make sense. If you’re not, it doesn’t really matter for the exam as long as you memorize the tag. (The details surrounding JNDI environment entries are covered in EJB/2EE books like the lovely Head First EJB.)

Think of an environment entry as being something like a deploy-time constant that your app can use, much like servlet and context init parameters. In other words, a way for the deployer to pass values into the servlet (or in this case, an EJB as well if this is deployed as part of an enterprise application in a fully 2EE-compliant server).

At deploy time, the Container reads the DD and makes a JNDI entry (again, assuming this is a fully 2EE-compliant app, and not just a server with only a web Container), using the name and value you supply in this DD tag. At runtime, a component in the application can look up the value in JNDI, using the name listed in the DD. You probably won’t care about `<env-entry>` unless you’re also developing with EJBs, so the only reason you need to memorize this is for the exam.

Declaring an app’s JNDI environment entry

```xml
<env-entry>
  <env-entry-name>rates/discountRate</env-entry-name>
  <env-entry-type>java.lang.Integer</env-entry-type>
  <env-entry-value>10</env-entry-value>
</env-entry>
```

When you see an `<env-entry-value>` that’s an integer value (like the example above), you might think that the `<env-entry-type>` can be a primitive. But that would be... wrong! You also might be tempted to think that you can have only Strings and wrappers, but that’s wrong too—you can use any type that takes a String in its constructor (or a single Character for a Character type).
Memorizing the `<mime-mapping>` DD tag

You can configure a mapping between an extension and a mime type in the DD. This will probably be the easiest tag to remember, because it just makes sense—you map between an extension and a mime-type, and guess what? In a rare moment of simplicity and clarity, they named the tag sub-elements “extension” and “mime-type”. That means you have to remember only one thing—that the tag elements are named for exactly what they are!

Unless you start thinking of it as “file-type” and “content-type”. But no, you won’t do that. You’ll memorize it just like this.

Declaring a `<mime-mapping>`

```xml
<mime-mapping>
  <extension>mpg</extension>
  <mime-type>video/mpg</mime-type>
</mime-mapping>
```

Don’t include the “.*” in the extension!

It’s just the characters that make up the extension, not the “.” that separates the file name from the extension.

It’s not `<file-type>` and `<content-type>`!

Burn it in—`<extension>` and `<mime-type>`, `<extension>` and `<mime-type>`.
`<extension>` and `<mime-type>`
`<extension>` and `<mime-type>`
`<extension>` and `<mime-type>`
### Where things go

Fill in this table with explicit notes on where in the web app the given resource must be placed. We did the first one for you. Turn the page for the answers.

<table>
<thead>
<tr>
<th>Resource type</th>
<th>Deployment location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deployment Descriptor</td>
<td>Directly inside WEB-INF (which is directly inside the root of the web app).</td>
</tr>
<tr>
<td>Tag Files (tag or tagx)</td>
<td></td>
</tr>
<tr>
<td>HTML and JSPs</td>
<td>(That you want to be directly accessible.)</td>
</tr>
<tr>
<td>HTML and JSPs</td>
<td>(That you want to “hide” from direct client access.)</td>
</tr>
<tr>
<td>TLDs (tld)</td>
<td></td>
</tr>
<tr>
<td>Servlet classes</td>
<td></td>
</tr>
<tr>
<td>Tag Handler classes</td>

Chapter 11. Deploying your web app
web app deployment

Memorizing DD tags

If you're NOT planning on taking the exam, don't worry about getting all of these right (although the bottom two elements are important to almost everyone).

If you ARE going to take the exam, you should spend some time memorizing these.

<e:jbانون>  
<e:jb-ref>Entity</e:jb-ref>
  <______>com.wickedlysmart.CustomerHome<______>
  <local>com.wickedlysmart.Customer</local>
  <______>

<e:jb-ref>
  <______>e:jb/localCustomer<______>
  <e:jb-ref-type>Entity</e:jb-ref-type>
  <______>com.wickedlysmart.CustomerHome<______>
  <______>com.wickedlysmart.Customer<______>
</e:jb-ref>

<env-entry>
  <______>rates/discountRate<______>
  <______>java.lang.Integer<______>
  <env-entry-value>10</env-entry-value>
</env-entry>

<error-page>
  <______>java.io.IOException<______>
  <_____>/myerror.jsp<______>
</error-page>

<______>
  <welcome-file>index.html</welcome-file>
  <______>
### Chapter 11. Deploying your web app

**Where things go**

Fill in this table with explicit notes on where in the web app the resource must be placed. We did the first one for you.

<table>
<thead>
<tr>
<th>Resource type</th>
<th>Deployment location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deployment Descriptor (web.xml)</td>
<td>Directly inside WEB-INF (which is directly inside the root of the web app)</td>
</tr>
<tr>
<td>Tag Files (tag or .tagx)</td>
<td>If NOT deployed inside a JAR, Tag Files must be inside WEB-INF/tags, or a subdirectory of WEB-INF/tags. If deployed in a JAR, Tag Files must be in META-INF/tags, or a subdirectory of META-INF/tags. Note: Tag Files deployed in a JAR must have a TLD in the JAR.</td>
</tr>
<tr>
<td>HTML and JSPs (That you want to be directly accessible.)</td>
<td>Client-accessible HTML and JSPs can be anywhere under the root of the web app or any of its subdirectories, EXCEPT they cannot be under WEB-INF (including subdirectories). In a WAR file, they can’t be under META-INF (including subdirectories).</td>
</tr>
<tr>
<td>HTML and JSPs (That you want to “hide” from direct client access.)</td>
<td>Pages under WEB-INF (or META-INF in a WAR file) cannot be directly accessed by clients.</td>
</tr>
<tr>
<td>TLDs (.tld)</td>
<td>If NOT inside a JAR, TLD files must be somewhere under WEB-INF or a subdirectory of WEB-INF. If deployed in a JAR, TLD files must be somewhere under META-INF, or a subdirectory of META-INF.</td>
</tr>
<tr>
<td>Servlet classes</td>
<td>Servlet classes must be in a directory structure matching the package structure, placed directory under WEB-INF/classes (for example, class com.exampleRING would be inside WEB-INF/classes/com/exampleRING) or in the appropriate package directories within a JAR inside WEB-INF/lib.</td>
</tr>
<tr>
<td>Tag Handler classes</td>
<td>Actually ALL classes used by the web-app (unless they’re part of the class libraries on the classpath) must follow the same rules as servlet classes—inside WEB-INF/classes, in a directory structure matching the package (or in the appropriate package directories within a JAR inside WEB-INF/lib).</td>
</tr>
<tr>
<td>JAR files</td>
<td>JAR files must be inside the WEB-INF/lib directory.</td>
</tr>
</tbody>
</table>
Memorizing DD tags

**ANSWERS**

If you are going to take the exam, you should spend some time memorizing ALL of these (plus any of the others from this chapter and the security-related tags you’ll see in the next chapter).

**A reference to a bean that has a “local” interface.**

```xml
<ejb-local-ref>
  <ejb-ref-name>ejb/Customer</ejb-ref-name>
  <ejb-ref-type>Entity</ejb-ref-type>
  <local-home>com.wickedlysmart.CustomerHome</local-home>
  <local>com.wickedlysmart.Customer</local>
</ejb-local-ref>
```

**A reference to a bean that has a “remote” interface.**

```xml
<ejb-ref>
  <ejb-ref-name>ejb/LocalCustomer</ejb-ref-name>
  <ejb-ref-type>Entity</ejb-ref-type>
  <home>com.wickedlysmart.CustomerHome</home>
  <remote>com.wickedlysmart.Customer</remote>
</ejb-ref>
```

**An environment entry is a way to get deploy-time constants into a J2EE application.**

```xml
<env-entry>
  <env-entry-name>rates/discountRate</env-entry-name>
  <env-entry-type>java.lang.Integer</env-entry-type>
  <env-entry-value>10</env-entry-value>
</env-entry>
```

**Tells the Container which page to show when the specified <exception-type> occurs.**

```xml
<error-page>
  <exception-type>java.io.IOException</exception-type>
  <location>/myerror.jsp</location>
</error-page>
```

**Tells the Container which page to look for when a request comes in that doesn’t match a specific resource. There can be more than one <welcome-file> specified in the <welcome-file-list>.**

```xml
<welcome-file-list>
  <welcome-file>/index.html</welcome-file>
</welcome-file-list>
```
mock exam

Mock Exam Cram

Mock Exam Chapter 11

1. Where can `<init-param>` elements appear in the DD? (Choose all that apply.)
   - A. As child elements of `<servlet>`.
   - B. As direct descendants of `<web-application>` elements.
   - C. Just after the Document Type Declaration.
   - D. Inside of `<context-param>` elements when you want to declare a context initialization parameter.

2. Where do you store Tag Library Descriptors (TLDs), in a web application? (Choose all that apply.)
   - B. Only in `/WEB-INF/classes`.
   - C. In the `/META-INF` directory of a JAR file inside `/WEB-INF/lib`.
   - D. At the application’s top-level directory.
   - E. In `/WEB-INF` or a sub-directory thereof.

3. Which statements about WAR files are true? (Choose all that apply.)
   - A. WAR stands for Web Application Resources file.
   - B. A valid WAR file must contain a deployment descriptor.
   - C. Several WAR files can compose a web application.
   - D. A WAR file cannot contain embedded JAR files.
The following servlet is declared in the DD:

```
<web-app>
  <servlet>
    <servlet-name>MyServlet</servlet-name>
    <servlet-class>com.myorg.ServletClass</servlet-class>
  </servlet>
</web-app>
```

Where can you store the servlet class in the web application? (Choose all that apply.)

- A. In `/META-INF` of a JAR file.
- B. In the package-related directory tree beginning at the top level of the application directory.
- C. In `/WEB-INF/classes` or in a JAR file in `/WEB-INF/lib`.
- D. In `/WEB-INF/lib` outside of a JAR file.

What is the purpose of the deployment descriptor (DD)? (Choose all that apply.)

- A. To allow code-generation tools to dynamically create.servlets from an XML file.
- B. To convey the web-application configuration information from developers to application assemblers and deployers.
- C. To configure vendor-specific aspects of the application.
- D. To configure only database and Enterprise JavaBean access from the web application.

Where should `web.xml` be stored in a WAR file? (Choose all that apply.)

- A. In `/WEB-INF/classes`.
- B. In `/WEB-INF/lib`.
- C. In `/WEB-INF`.
- D. In `/META-INF`.

...
mock exam

Given:

10. `<%@ page import="java.util.*" %>
11. `<jsp:import import="java.util.*" />
12. `<jsp:directive.page import="java.util.*" />
13. `<jsp:page import="java.util.*" />

Assume the prefix "jsp" has been mapped to the namespace http://java.sun.com/JSP/Page.

Which are true? (Choose all that apply.)

- A. Lines 10 and 12 are equivalent in any type of JSP page.
- B. Line 10 is not valid in a JSP document (XML-based document).
- C. Line 11 will properly import the java.util package.
- D. Line 12 will properly import the java.util package.
- E. Line 13 will properly import the java.util package.

Which statements about `<init-param>` DD elements are true? (Choose all that apply.)

- A. They are used to declare initialization parameters for a specific servlet.
- B. They are used to declare initialization parameters for an entire web app.
- C. The method that retrieves these parameters returns an object.
- D. The method that retrieves these parameters takes a String.

Which are DD elements that provide JNDI access to J2EE components? (Choose all that apply.)

- A. `<ejb-ref`
- B. `<entity-ref`
- C. `<resource-ref`
- D. `<session-ref`
- E. `<message-ref`

608  chapter 11
The following servlet is registered in the DD:

```xml
<servlet>
  <servlet-name>action</servlet-name>
  <servlet-class>com.myorg.ActionClass</servlet-class>
</servlet>
```

Choose the correct mappings for this servlet. (Choose all that apply.)

- A. `<servlet-mapping>
   <servlet-name>action</servlet-name>
   <url-pattern>*.do</url-pattern>
</servlet-mapping>`

- B. `<servlet-mapping>
   <servlet-name>com.myorg.ActionClass</servlet-name>
   <url-pattern>*.do</url-pattern>
</servlet-mapping>`

- C. `<servlet-mapping>
   <servlet-name>action</servlet-name>
   <url-pattern>/controller</url-pattern>
</servlet-mapping>`

- D. `<servlet-mapping>
   <url-pattern>*.do</url-pattern>
</servlet-mapping>`

- E. `<servlet-mapping>
   <servlet-name>action</servlet-name>
</servlet-mapping>`

For which type of web app components can dependencies be defined? (Choose all that apply.)

- A. JSP files
- B. WAR files
- C. classes
- D. libraries
- E. manifest files
mock exam

12. Which are valid declarations in a JSP Document (XML-based document)? (Choose all that apply.)
   - A. `<jsp:declaration
       xmlns:jsp="http://java.sun.com/JSP/Page">
           int x = 0;
       </jsp:declaration>
   - B. `<jsp:declaration
       xmlns:jsp="http://java.sun.com/JSP/Page">
           int x;
       </jsp:declaration>
   - C. `<%! int x = 0; %>`
   - D. `<%! int x; %>`

13. Which 2.4 deployment descriptor elements may appear before the `<web-app>` element? (Choose all that apply.)
   - A. `<listener>`
   - B. `<context-param>`
   - C. `<servlet>`
   - D. No XML elements may appear before the `<web-app>` element.

14. Which statements concerning the container class loader are true? (Choose all that apply.)
   - A. Web applications should NOT attempt to override container implementation classes.
   - B. A web application must not attempt to load resources from within the WAR file using the J2EE semantics of `getResource`.
   - C. A web application may override any J2EE classes in the `javax.*` namespace.
   - D. A web developer may override J2EE platform classes provided they are contained in a library JAR within a WAR.
Where can `<init-param>` elements appear in the DD? (Choose all that apply.)

- A. As child elements of `<servlet>`.
- B. As direct descendants of `<web-application>` elements.
- C. Just after the Document Type Declaration.
- D. Inside of `<context-param>` elements when you want to declare a context initialization parameter.

Where do you store Tag Library Descriptors (TLDs), in a web application? (Choose all that apply.)

- B. Only in `/WEB-INF/classes`.
- C. In the `/META-INF` directory of a JAR file inside `/WEB-INF/lib`.
- D. At the application’s top-level directory.
- E. In `/WEB-INF` or a sub-directory thereof.

Which statements about WAR files are true? (Choose all that apply.)

- A. WAR stands for Web Application Resources file.
- B. A valid WAR file must contain a deployment descriptor.
- C. Several WAR files can compose a web application.
- D. A WAR file cannot contain embedded JAR files.
mock answers

4. The following servlet is declared in the DD:

```
<Servlet>
  <servlet-name>MyServlet</servlet-name>
  <servlet-class>com.myorg.ServletClass</servlet-class>
</Servlet>
```

Where can you store the servlet class in the web application? (Choose all that apply)

- A. In `/META-INF` of a JAR file.
- B. In the package-related directory tree beginning at the top level of the application directory.
- C. In `/WEB-INF/classes` or in a JAR file in `/WEB-INF/lib`.
- D. In `/WEB-INF/lib` outside of a JAR file.

- Option D is not correct because `/WEB-INF/lib` is designed as the container for JAR files.

5. What is the purpose of the deployment descriptor (DD)? (Choose all that apply)

- A. To allow code-generation tools to dynamically create servlets from an XML file.
- B. To convey the web-application configuration information from developers to application assemblers and deployers.
- C. To configure vendor-specific aspects of the application.
- D. To configure only database and Enterprise JavaBean access from the web application.

- Option D is inaccurate because these concerns are just a subset of the DD's purpose.

6. Where should `web.xml` be stored in a WAR file? (Choose all that apply)

- A. In `/WEB-INF/classes`.
- B. In `/WEB-INF/lib`.
- C. In `/WEB-INF`.
- D. In `/META-INF`.

- `web.xml` should be stored in `/WEB-INF` regardless of whether the deployment involves a WAR or an exploded directory structure.

- Option D is not correct because `/META-INF` is designed as the container for JAR files.
### Given:

10. `<%@ page import="java.util.*" %>`
11. `<jsp:import import="java.util.*" />`
12. `<jsp:directive.page import="java.util.*" />`
13. `<jsp:page import="java.util.*" />`

Assume the prefix "jsp" has been mapped to the namespace `http://java.sun.com/JSP/Page`.

Which are true? (Choose all that apply.)

- A. Lines 10 and 12 are equivalent in any type of JSP page.
- B. Line 11 is not valid in a JSP document (XML-based document).
- C. Line 11 will properly import the `java.util` package.
- D. Line 12 will properly import the `java.util` package.
- E. Line 13 will properly import the `java.util` package.

### Which statements about `<init-param>` DD elements are true? (Choose all that apply.)

- A. They are used to declare initialization parameters for a specific servlet.
- B. They are used to declare initialization parameters for an entire web app.
- C. The method that retrieves these parameters returns an object.
- D. The method that retrieves these parameters takes a String.

### Which are DD elements that provide JNDI access to J2EE components? (Choose all that apply.)

- A. `<servlet-ref>`
- B. `<entity-ref>`
- C. `<resource-ref>`
- D. `<session-ref>`
- E. `<message-ref>`
mock answers

10 The following servlet is registered in the DD:

```
<servlet>
  <servlet-name>action</servlet-name>
  <servlet-class>com.myorg.ActionClass</servlet-class>
</servlet>
```

Choose the correct mappings for this servlet. (Choose all that apply.)

- A. `<servlet-mapping>
   <url-pattern>*.do</url-pattern>
   <servlet-name>action</servlet-name>
 </servlet-mapping>`

- B. `<servlet-mapping>
   <url-pattern>*.do</url-pattern>
   <servlet-name>com.myorg.ActionClass</servlet-name>
 </servlet-mapping>`

- C. `<servlet-mapping>
   <url-pattern>/controller</url-pattern>
   <servlet-name>action</servlet-name>
 </servlet-mapping>`

- D. `<servlet-mapping>
   <url-pattern>*.do</url-pattern>
   <servlet-name>controller</servlet-name>
 </servlet-mapping>`

- E. `<servlet-mapping>
   <url-pattern>*.do</url-pattern>
   <servlet-name>action</servlet-name>
 </servlet-mapping>`

11 For which type of web app components can dependencies be defined? (Choose all that apply.)

- A. JSP files
- B. WAR files
- C. classes
- D. libraries
- E. manifest files

Note: Libraries dependencies can be defined in the `/META-INF/MANIFEST.MF` file.
Which are valid declarations in a JSP Document (XML-based document)? (Choose all that apply.)

- A. `<jsp:declaration>`
  ```xml
  xmlns:jsp="http://java.sun.com/JSP/Page">
  int x = 0;
  </jsp:declaration>
  ```
- B. `<jsp:declaration>`
  ```xml
  xmlns:jsp="http://java.sun.com/JSP/Page">
  int x;
  </jsp:declaration>
  ```
- C. `<!-- int x = 0; -->`
- D. `<!-- int x; -->`

Which 2.4 deployment descriptor elements may appear before the `<web-app>` element? (Choose all that apply.)

- A. `<listener>`
- B. `<context-param>`
- C. `<servlet>`
- D. No XML elements may appear before the `<web-app>` element.

Which statements concerning the container class loader are true? (Choose all that apply.)

- A. Web applications should NOT attempt to override container implementation classes.
- B. A web application must not attempt to load resources from within the WAR file using the J2SE semantics of `getResource`.
- C. A web application may override any J2EE classes in the `java.*` namespace.
- D. A web developer may override J2EE platform classes provided they are contained in a library JAR within a WAR.
Your web app is in danger. Trouble lurks in every corner of the network, as crackers, scammers, and criminals try to break into your system to steal, take advantage, or just have a little fun with your site. You don’t want the Bad Guys listening in to your online store transactions, picking off credit card numbers. You don’t want the Bad Guys convincing your server that they’re actually the Special Customers Who Get Big Discounts. And you don’t want anyone (good or bad) looking at sensitive employee data. Does Jim in marketing really need to know that Lisa in engineering makes three times as much as he does? And do you really want Jim to take matters into his own hands and login (unauthorized) to the UpdatePayroll servlet?
official Sun exam objectives

OBJECTIVES

Servlets & JSP overview

5.1 Based on the servlet specification, compare and contrast the following security issues:
(a) authentication, (b) authorization, (c) data integrity, and (d) confidentiality.

5.2 In the deployment descriptor, declare the following: a security constraint, a Web resource, the transport guarantee, the login configuration, and a security role.

5.3 Given an authentication type (BASIC, DIGEST, FORM, and CLIENT-CERT), describe its mechanism.

Coverage Notes:

All of the objectives in this section are covered completely in this chapter, including security-related DD elements that were NOT covered in the deployment chapter.

We can’t make you a complete security being, but the content in this chapter is a start, and it’s everything you need for the exam.
The Bad Guys are everywhere

As a web application developer you need to protect your web site. There are three main kinds of bad guys you need to watch out for: Impersonators, Upgraders, and Eavesdroppers.

Evil Impersonator

I'm in too! I'm already a regular member, but now I figured out how to sneak in to the Premium Members area, and now I can do ANYTHING.

Naughty Upgrader
And it’s not just the **server** that gets hurt...

Eavesdroppers can be the worst. Not only are they trying to scam your web app, but they can burn some of your good clients too. A double hit. If an eavesdropper is successful, he’ll swipe your client’s credit card information and charge up a storm.

![Diagram showing an innocent user sending credit card information to a server, which is intercepted by an evil eavesdropper](image-url)
The Big 4 in servlet security

Servlet security helps you—the web app developer—foil Impersonators, Upgraders, and Eavesdroppers. As far as the servlet specification is concerned (and hence, the exam), servlet security boils down to four main concepts: authentication, authorization, confidentiality, and data integrity.
Bob’s security project

A little security story

One day Bob’s boss called Bob into his office. “I’ve got an exciting new project for you!” his boss said. Bob groaned. “I know I’ve handed you some bad jobs in the past, but this one should be really fun... I’d like you to design the security for our company’s new eCommerce web site.”

“Security” Bob said, “is hard and boring.” “No you’re wrong...” the boss said. “In J2EE 1.4, servlet security is supposed to be pretty cool.”

The boss continued, “Let me give you the elevator pitch to get you going, then we’ll go into details once you’ve had a chance to think this through.”

“Oh, Bob sighed, “Lay it on me.”

“As you know, this beer website is really hot right now. We’ve added several new features, and we’re getting a great response. Some of our users are happy with just the free recipes we offer, but a lot more people than we thought are willing to pay for our rare hops and other premium ingredients. Oh, and our Frequent Brewer program is a huge hit. If a user decides he’ll be a repeat ingredient buyer, he can pay a one time fee and upgrade to Brew Master status. A Brew Master get special discounts, and earns Frequent Brewer points which he can redeem for cool brew rewards.”

Bob continued to listen, mentally calculating the code he’ll have to write to implement all this, and kissing that tropical vacation goodbye. Meanwhile, the boss continued...

“But now we have to make sure that when one of our users makes a purchase, no one can swipe his credit card information. Oh, another thing, we’d better make sure that when a member logs in, it’s not actually one of his friends trying to sneak in. I think we need to require that members have passwords from now on.”

“It’s all making sense so far,” said Bob. “When users place an order with us, do we want to give them some sort of confirmation code?” “Great idea,” said the boss. “Oh, and one more thing I forgot—you better make sure that only our Frequent Brewers get the special discounts.”

“I think this is enough,” said the boss. “But you know... the way things are going, it probably won’t be too long before we offer some sort of platinum membership level...”

FLEX YOUR MIND

Which security concepts are mentioned in the story?

Reread the story and annotate the places where the boss’s requirements call for:

- authentication
- authorization
- confidentiality
- data integrity

(Yes, yeah, we know this is obvious, but we’re just warming up the topic before it gets down and dirty.)

622  chapter 12
AUTHENTICATION - Whenever someone mentions passwords, they're probably talking about authentication... is this guy who he says he is? If so, he should know his password!

AUTHORIZATION - Once we have established who we're talking to, we want to make sure that they're allowed to do what they want to do.

CONFIDENTIALITY - It would be a terrible security breach if a user's credit card number fell into the wrong hands!

CONFIDENTIALITY & DATA INTEGRITY - At this point the server is returning important and private information. It would be bad if the information was seen or altered by an eavesdropper.

Chapter 12. Keep it secret, keep it safe
HTTP authentication

How to Authenticate in HTTP World:
the beginning of a secure transaction

Let’s start with a look at the communications that occur between a browser and a web container when the client asks for a secure resource on the website. It’s BASIC, really.

**The HTTP perspective...**

1. The browser makes a request for a web resource, “update.jsp”.
2. The server determines that “update.jsp” is a constrained resource.
3. The container sends back an HTTP 401 (“Unauthorized”), with a www-authenticate header and realm information.
4. The browser gets the 401, and, based on the Realm info, asks the user for his username and password.
5. The browser asks for “update.jsp” again (stateless, remember), but this time the request includes a security HTTP header, and a username and password.
6. The Container verifies that the username and password match, and if they do, performs authorization.
7. If all the security stuff is good, the Container returns the HTML, if not it returns another HTTP 401...
A slightly closer look at how the Container does Authentication and Authorization

On the last page we skimmed over what the Container was doing. Throughout this chapter we’ll hit different levels of detail, and here we zoom in just a little...

### The Container perspective...

1. Having received the request, the container finds the URL in the “security table” (stored in whatever the Container is using to keep security info).
2. If the Container finds the URL in the security table, it checks to see whether the requested resource is constrained. If it is, it returns 401...

---

**The initial request, NO password**

---

**The second request, WITH password**

1. When the Container receives a request with a username and password, it checks the URL in the security table.
2. If it finds the URL in the security table (and sees that it’s constrained), it checks the username and password information to make sure they match.
3. If the username and password are OK, the Container checks to see if the user has been assigned the correct ‘role’ to access this resource (i.e. authorization). If so, the resource is returned to the client.
How did the Container do that?

You just got an overview of how the Container handles authentication and authorization. But what was going on inside the Container that made all that happen? Let’s speculate a little on what was going on behind the scenes, deep down in the heart of the Container...

Things the Container did:

1. Performed a lookup on the resource being requested

   We already know that the Container is really good at finding resources. But now, once it finds the resource, it has to determine whether it’s a resource that anyone can view, or whether the resource has security constraints. Does the servlet itself have some sort of security flag? Is there a table somewhere?

2. Performed some authentication

   Once the Container determines that it’s dealing with a secured resource, it has to authenticate the client. In other words, to find out if “Bob” really is Bob. (The most common way is to see if Bob knows his own password.)

3. Performed some authorization

   Once the Container determines that it is the real Bob asking for this resource, the Container has to see whether Bob is allowed access to that resource. Let’s see, if we have 2,000,000 users, and 100 servlets in our webapp, we could throw together a little table with 200,000,000 cells...

   Whoo! This could get out of hand in a hurry if we’re not careful.

FLEX YOUR MIND

Which bits of security logic and information should be hardcoded in the servlet?

- names and passwords?
- users roles?
- access rules for each servlet?
Keep security out of the code!
For most web apps, most of the time, the web app’s security constraints should be handled declaratively, in the deployment descriptor. Why?

Top Ten Reasons to do your security declaratively

1. Who doesn’t need more XML practice?
2. Often maps naturally to the existing job roles in a company’s IT department.
3. Looks great on your resume.
4. Allows you to use servlets you’ve already written in more flexible ways.
5. It’s on the exam.
6. Allows application developers to reuse servlets without access to the source code.
7. It’s just cool.
8. Reduces ongoing maintenance when your application grows.
9. Finally, a way to justify the cost of that Container...
10. Supports the idea of component-based development.
who does security

Who implements security in a web app?

My job is easy. Most of the time, I don’t even have to think about security when I’m writing a servlet. And that’s good, because my philosophy is “Security is hard... don’t do it.”

My job is more involved. I decide which roles make sense in the application. For Kim’s beer application Guest, Member, and Admin are key roles. Then I add these roles to the users in our Container’s users file. Since we use tomcat, our file is called tomcat-users.xml.

My job is huge! Once I have a list of Annie’s roles, and a description of what Kim’s servlets do, I can decide which roles should have access to which servlets. The deployment descriptor provides me with an easy, somewhat verbose, way to tell the Container who has access to which servlets. And let me tell you, they don’t pay me enough...

Kim the servlet provider

Annie the application administrator

Dick the deployer
Questions to
Dummies

Q: I'm confused—if I'm creating servlets, shouldn't I be thinking about security considerations?

A: Yes, you should. Kim the servlet provider was being a little sarcastic. A key point when designing servlets is their modularity. For instance, it makes sense to separate browsing capabilities from updating capabilities. If these two use cases are implemented in separate servlets then it will be easy for the deployer to assign different security constraints to them.

Q: I don't know where YOU work, but in my situation I have to wear all three hats: developer, admin, and deployer.

A: That's actually a very common situation. We still recommend that when you're implementing security you do it in stages and "imagine" that you're wearing one hat at a time.

Q: How does programmatic security fit into the picture?

A: We'll get to programmatic security later in the chapter. For now, what's important to know is that you'll probably find that 95% of the security work you'll do in servlets will be declarative. Programmatic security just isn't used very much. (See "Top Ten Reasons..."?)

Q: So far everything you've talked about is related to authentication and authorization, how about the other two in the "big 4"?

A: We'll talk about confidentiality and data integrity later in this chapter. The servlet specification makes implementing these concepts very easy, so we're focusing on authentication and authorization because they're the most complicated to understand and implement, and, hint hint, more likely to show up on the exam.

Q: It seems like when people talk about servlet security the term "role" is overloaded...

A: Good point! When Sun designs J2EE specs (EJB, servlets, JSPs), they often think in terms of the kinds of people who might create and administer these components. In other words, IT-related job roles. When developers tackle security for web apps, they think about the types of users that might exist. For instance a "guest" might have very few privileges within a web app, and a "member" might have more privileges. These "user roles" are defined, mapped, and fretted over in the Deployment Descriptor.

Q: I've heard about something called "cross-site" hacking. What is that?

A: Cross-site hacking can happen when a website displays free form text entered by other users (for instance, a user book review). If a malicious user keys some HTML with, say, Javascript into a text area, and the server doesn't catch it, then unsuspecting browsers will render the potentially dangerous hidden code along with the good HTML when the page is served. In other words, the server sends to users something another user typed in, without checking or processing it for malicious scripting code.

Q: So we've got to deal with 'The Big Four'. How hard is it to set these babies up and maintain them, I mean is this going to be painful?

A: Yes, we're afraid it might hurt a little. Actually, some aspects of security are really low overhead, while others do require a fair amount of work. But none of it is very complicated, just potentially tedious.
**The Big Jobs in servlet security**

The table below will give you a feel for the key items in servlet security. **Authorization** is the most time-consuming to implement and **Authentication** is next. From the servlet perspective, Confidentiality and Data Integrity are pretty easy to set up. *Actually, getting the SSL certification is not trivial, so by “easy” we mean “you don’t really do anything in your servlet code.”*

We’re going to emphasize Authorization in this chapter because it’s the most important and complex of the vendor-neutral security concepts.
Just enough Authentication to discuss Authorization

Later in the chapter we’ll go deeper into authentication, but for now we’ll look at getting just enough authentication data into the system so that we can focus on authorization. A user can’t be authorized until he’s been authenticated.

The servlet specification doesn’t talk about how a Container should implement support for authentication data, including usernames and passwords. But the general idea is that the Container will supply a vendor-specific table containing usernames and their associated passwords and roles. But virtually all vendors go beyond that and provide a way to hook into your company-specific authentication data, often stored in a relational database or LDAP system (which is beyond the scope of this book). Typically, this data is maintained by the administrator.

The security “realm”

Unfortunately, realm is yet another overloaded term in the security world. As far as the servlet spec is concerned, a realm is a place where authentication information is stored. When you’re testing your application in Tomcat, you can use a file called “tomcat-users.xml” (located in tomcat’s conf/directory, NOT within webapps). That one “tomcat-users.xml” file applies to ALL applications deployed under webapps. It’s commonly known as the memory realm because Tomcat reads this file into memory at startup time. While it’s great for testing, it’s not recommended for production. For one thing you can’t modify its contents without restarting Tomcat.

The tomcat-users.xml file

```xml
<tomcat-users>
  <role rolename="Guest"/>
  <role rolename="Member"/>
  <user name="Bill" password="coder" roles="Member, Guest"/>
...
</tomcat-users>
```

The control for authentication is located in some sort of data structure like this. In Tomcat, you can use an XML file called “tomcat-users.xml” that holds name-password-role sets that the Container uses at authentication time.

Enabling authentication

To get authentication working (in other words, to get the Container to ask for a username and password), you need to stick something in the DD. Don’t worry about what this means for now, but if you want to start playing around with authentication, use this:

```xml
<login-config>
  <auth-method>BASIC</auth-method>
</login-config>
```

Remember! This is NOT part of the DD; it’s vendor-specific.
Authorization Step 1: defining roles

The most common form of authorization in servlets is for the container to determine whether a specific servlet—and the invoking HTTP request method—can be called by a user who has been assigned a certain security "role". So the first step is to map the "role" in the vendor-specific "users" file to roles established in the Deployment Descriptor.

Vendor-Specific: The <role> element in tomcat-users.xml

```
<tomcat-users>
    <role rolename="Admin"/>
    <role rolename="Member"/>
    <role rolename="Guest"/>
    <user username="Annie" password="admin" roles="Admin, Member, Guest" />
    <user username="Diane" password="coder" roles="Member, Guest" />
    <user username="Ted" password="newbie" roles="Guest" />
</tomcat-users>
```

Servlet-Specification: The DD <security-role> element in web.xml

```
<security-role>
    <role-name>Admin</role-name>
    <role-name>Member</role-name>
    <role-name>Guest</role-name>
</security-role>
```

When it's time for authorization, the container will map its vendor-specific "role" information to whatever <role-name>s it finds in your DD's <security-role> elements.

Don't forget that you always need the <login-config> element if you want to enable authentication.

The deployer creates <role-name> elements in the DD, so that the container can map roles to users.
Authorization Step 2: defining resource/method constraints

Finally, the cool part. This is where we get to specify, declaratively, that a given resource/method combination is accessible only by users in certain roles. Most of the security work you’ll do is probably with <security-constraint> elements in your DD. (Lots of picky rules later.)

<security-constraint> element in the DD:

```
<security-constraint>
  <web-resource-collection>
    <web-resource-name>UpdateRecipes</web-resource-name>
    <url-pattern>/Beer/AddRecipe/*</url-pattern>
    <url-pattern>/Beer/ReviewRecipe/*</url-pattern>
    <http-method>GET</http-method>
    <http-method>POST</http-method>
  </web-resource-collection>
  <auth-constraint>
    <role-name>Admin</role-name>
    <role-name>Member</role-name>
  </auth-constraint>
</security-constraint>
```

Both of us are allowed to do a GET and POST on the resources in the /Beer/AddRecipe directory and the /Beer/ReviewRecipe directory.

Bummer. My role (guest) is not listed under <auth-constraint>, so I cannot do a GET or POST on anything in those directories. But I CAN do a TRACE, HEAD, PUT...

Because they’re in the “Member” role, Diane and Annie can do GET and POST on resources that fit the url-pattern elements. Ted is only a “Guest”, so he can’t do a GET or POST.
<security-constraint> rules

The <security-constraint> rules for <web-resource-collection> elements

Remember; the purpose of the <web-resource-collection> sub-element is to tell the container which resources and HTTP Method combinations should be constrained. We wish we could tell you to relax here, but you really do need to know the details of these elements. If you make one little mistake in the security part of your DD, you could leave the most sensitive parts of your app open to... everyone.

You might get away with an unattractive web site, but if you screw up security... no, it's too disturbing to think about. (We're just trying to scare you into paying attention for the next few pages.)

The <web-resource-collection> sub-element of <security-constraint>

    <web-app...>
    <security-constraint>
      <web-resource-collection>
        <web-resource-name>UpdateRecipes</web-resource-name>
        <url-pattern>/Seer/AddRecipe/*</url-pattern>
        <url-pattern>/Seer/ReviewRecipe/*</url-pattern>
        <http-method>GET</http-method>
      </web-resource-collection>
      <auth-constraint>
        ... ...
      </auth-constraint>
    <security-constraint>
    </web-app>

Key points about <web-resource-collection>

- The <web-resource-collection> element has two primary sub-elements:
  - <url-pattern> (one or more).
  - <http-method> (optional, zero or more).
- The URL patterns and HTTP Methods work together to define resource requests that are constrained.
- A <web-resource-name> element is MANDATORY (even though you probably won't use it for anything yourself). (Assume it's for IDE or future use.)
- A <description> element is OPTIONAL.
- The <url-pattern> element uses servlet standard naming and mapping rules (refer back to the deployment chapter for details on URL patterns).
- You must specify at least one <url-pattern>, but you can have many.
- Valid Methods for the <http-method> element are: GET, POST, PUT, TRACE, DELETE, HEAD, and OPTIONS.
- If no HTTP Methods are specified then ALL Methods will be constrained!
- If you DO specify an <http-method>, then only those methods specified will be constrained. In other words, once you specify even a single <http-method>, you automatically enable any HTTP Methods which you have not specified.
- You can have more than one <web-resource-collection> element in the same <security-constraint>.
- The <auth-constraint> element applies to ALL <web-resource-collection> elements in the <security-constraint>. 

These are the directories with constraints.

Chapter 12. Keep it secret, keep it safe

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham

Chapter 12. Keep it secret, keep it safe

If you specify an <http-method> element, all the HTTP methods you do NOT specify are unconstrained!

The web server's job is to serve, so the default assumption is that you want the HTTP Methods to be unconstrained unless you explicitly say (using the <http-method>) that you want a method to be constrained (for the resources that match the <url-pattern>). If you put in only an <http-method>=GET, that means anybody, regardless of security role (or even regardless of whether the client is authenticated), can invoke those HTTP Methods.

BUT... this is true only if you have specified at least one <http-method> element. If you do NOT specify any <http-method> element, then you're constraining ALL HTTP Methods. (You'll probably never do that, because the whole point of a security constraint is to constrain specific HTTP requests on a particular set of resources.)

Of course, HTTP Methods won't work in a servlet unless you've overridden the doXXX() method, so if you have only a doGet() in your servlet and you specify an <http-method> element for only GET, nobody can do a POST anyway, because the server knows you don't support POST.

So we can modify the rule a little to say: any HTTP Methods supported by your servlet (because you override the matching service method) will be allowed unless you do one of two things:

1) Do not specify ANY <http-method> elements in the <security-constraint>, which means that ALL Methods are constrained.

2) Explicitly list the Method using the <http-method> element.
<auth-constraint> rules

Picky <security-constraint> rules for <auth-constraint> sub-elements

Even though it’s got <auth-constraint> in its name, this is the sub-element that specifies which roles are ALLOWED to access the web resources specified by the <web-resource-collection> sub-element(s).

The <auth-constraint> sub-element of <security-constraint>

```xml
<web-app>
...<security-constraint>
  <web-resource-collection>
    ...
  </web-resource-collection>
  <auth-constraint>
    <role-name>Admin</role-name>
    <role-name>Member</role-name>
  </auth-constraint>
</security-constraint>
</web-app>
```

<role-name> rules

- Within an <auth-constraint> element, the <role-name> element is OPTIONAL.
- If <role-name> elements exist, they tell the Container which roles are ALLOWED.
- If an <auth-constraint>-element exists with NO <role-name> element, then NO USERS ARE ALLOWED.
- If <role-name>元素 then ALL users are ALLOWED.
- Role names are case-sensitive.

<auth-constraint> rules

- Within a <security-constraint> element, the <auth-constraint> element is OPTIONAL.
- If an <auth-constraint> exists, the Container MUST perform authentication for the associated URLs.
- If an <auth-constraint> does NOT exist, the Container MUST allow unauthenticated access for these URLs.
- For readability, you can add a <description> inside <auth-constraint>.
### The way `<auth-constraint>` works

<table>
<thead>
<tr>
<th>Contents of <code>&lt;auth-constraint&gt;</code></th>
<th>Which roles have access</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;security-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;role-name&gt;Admin&lt;/role-name&gt;</code></td>
<td>Admin</td>
</tr>
<tr>
<td><code>&lt;role-name&gt;Member&lt;/role-name&gt;</code></td>
<td>Member</td>
</tr>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;security-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;role-name&gt;Guest&lt;/role-name&gt;</code></td>
<td>Guest</td>
</tr>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;security-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;role-name&gt;*&lt;/role-name&gt;</code></td>
<td>Everybody</td>
</tr>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;security-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;role-name&gt;</code></td>
<td>Nobody</td>
</tr>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;security-constraint&gt;</code></td>
<td></td>
</tr>
</tbody>
</table>

If there is NO `<auth-constraint>`

Everybody

**NO `<auth-constraint>` is the opposite of an EMPTY `<auth-constraint>`!**

Remember this: If you don’t say which roles are constrained, then NO roles are constrained. But once you do put in an `<auth-constraint>`, then ONLY the roles explicitly stated are allowed access (unless you use the wildcard “*” for the `<role-name>`). If you don’t want ANY role to have access, you MUST put the `<auth-constraint>`, but just leave it empty. This tells the Container, “I am explicitly stating the roles allowed and, by the way, there aren’t any!”
**How multiple `<security-constraint>` elements interact**

Just when you thought you had `<security-constraint>` figured out, you realize that multiple `<security-constraint>` elements might conflict. Look at the DD fragments below, and imagine the different combinations of `<auth-constraint>` configurations that might be used.

What happens, for example, if one `<security-constraint>` denies access while another `<security-constraint>` explicitly grants access... to the same constrained resource, for the same role? Which `<security-constraint>` wins? The table on the opposite page has all the answers.

**Multiple `<security-constraint>` elements with the same (or partly-matching) URL patterns and `<http-method>` elements:**

- `<security-constraint>`
  - `<web-resource-collection>`
  - `<web-resource-name>` Recipes
  - `<url-pattern>`/Beer/DisplayRecipes/*
  - `<url-pattern>`/Beer/UpdateRecipes/*
  - `<http-method>`POST/HTTP-method
  - `<web-resource-collection>`

- `<security-constraint>`
  - `<web-resource-collection>`
  - `<web-resource-name>` Update
  - `<url-pattern>`/Beer/UpdateRecipes/*
  - `<http-method>`POST/HTTP-method
  - `<web-resource-collection>`

**How should the container handle authorization when the same resource is used by more than one `<security-constraint>`?**
### Dueling `<auth-constraint>` elements

If two or more `<security-constraint>` elements have partially or fully overlapping `<web-resource-collection>` elements, here's how the container resolves access to the overlapping resources. A and B refer to the DD on the previous page.

<table>
<thead>
<tr>
<th>Contents of A</th>
<th>Contents of B</th>
<th>Who has Access to ‘UpdateRecipes’</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td><code>&lt;auth-constraint&gt;</code></td>
<td>Guests and Admins</td>
</tr>
<tr>
<td><code>&lt;role-name&gt;Guest&lt;/role-name&gt;</code></td>
<td><code>&lt;role-name&gt;Admin&lt;/role-name&gt;</code></td>
<td>Nobody</td>
</tr>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td><code>&lt;auth-constraint&gt;</code></td>
<td>Everybody</td>
</tr>
<tr>
<td><code>&lt;role-name&gt;Guest&lt;/role-name&gt;</code></td>
<td><code>&lt;role-name&gt;*&lt;/role-name&gt;</code></td>
<td>Nobody</td>
</tr>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td><code>&lt;auth-constraint&gt;</code></td>
<td>Everybodty</td>
</tr>
<tr>
<td><code>&lt;role-name&gt;Admin&lt;/role-name&gt;</code></td>
<td><code>&lt;role-name&gt;Admin&lt;/role-name&gt;</code></td>
<td>Everybody</td>
</tr>
<tr>
<td><code>&lt;auth-constraint&gt;</code></td>
<td><code>&lt;auth-constraint&gt;</code></td>
<td>Everybody</td>
</tr>
</tbody>
</table>

**Rules for interpreting this table:**

1. When combining individual role names, all of the role names listed will be allowed.
2. A role name of `*` combines with anything else to allow access to everybody.
3. An empty `<auth-constraint>` tag combines with anything else to allow access to nobody! In other words, an empty `<auth-constraint>` is always the final word!
4. If one of the `<security-constraint>` elements has no `<auth-constraint>` element, it combines with anything else to allow access to everybody.

When two different non-empty `<auth-constraint>` elements apply to the same constrained resource, access is granted to the union of all roles from both of the `<auth-constraint>` elements.
security constraints

Q: Why does the <auth-constraint> element go inside <security-constraint> but NOT inside the <web-resource-collection> element?

A: This way, you can specify a single <auth-constraint> element (which could include multiple roles), and then specify multiple resource collections for which the <auth-constraint> role list applies. For example, you might define an <auth-constraint> for a Frequent Buyer role, and then put <web-resource-collection> elements in for all the different parts of the web app where a Frequent Buyer gets special access.

Q: I understand that putting in an empty <auth-constraint/> element tells the Container that NOBODY from any role can access the constrained resource. But I don't understand WHY you would ever do that. What good is a resource that nobody can access?

A: When we said, "NOBODY", we meant, "Nobody from OUTSIDE the web app". In other words, a client can't access the constrained resource, but another part of the web app can. You might want to use a request dispatcher to forward to another part of the web app, but you don't ever want clients to request that resource directly. Think of 100% constrained resources as sort of like private methods in a Java class—for internal use only.

Q: Do I actually have to sit there and type in every one of my users with their passwords and roles?

A: If you're using the test memory realm from Tomcat, yes. But chances are, in the real world you're using a production server that gives you a hook into the LDAP or database where your real user security info is stored.
Alice’s recipe servlet, a story about programmatic security...

Alice knows that most of the time declarative security is the way to go. It’s flexible, powerful, portable, and robust. As web application architectures have evolved, individual servlets have become more and more specialized. In the old days, a single servlet would be used to provide business logic to support employees and managers. Today, these functions would probably be split into at least two distinct servlets.

But, lucky Alice has just inherited someone else’s “RecipeServlet”. Alice has heard a rumour that RecipeServlet uses programmatic security, so she starts looking through the source code and finds this snippet...

```java
if( request.isUserInRole("Manager") ) {
   // do the UpdateRecipe page
   ...
} else {
   // do the ViewRecipe page
   ...
}
```

What are the implications?

Think about what you’ve learned so far in this chapter, look at the small code snippet above, and try to answer the questions.

- What security step must have happened before this snippet runs?
- What security step is implied by this snippet?
- What part, if any, does the DD play in this snippet?
- How do you think this code works?
- What if the role of “Manager” doesn’t exist in your container?
the `isUserRole()` method

**Customizing methods: `isUserRole()`**

In `HttpServletRequest`, three methods are associated with programmatic security:

`getUserPrincipal()`, which is mainly used with EJBs. We won’t cover it in this book.

`getRemoteUser()`, which can be used to check authentication status. It’s not commonly used, so we don’t cover it in this book (and there’s nothing else you need to know about it for the exam).

`isUserRole()`, which we’ll look at now. Instead of authorizing at the HTTP method level (GET, POST, etc.), you can authorize access to `portions` of a method. This gives you a way to customize how a service method behaves based on the user’s role. If you’re in this service method (doGet(), doPost(), etc.), then the user made it through the declarative authorization, but now you want to do something in the method conditionally, based on whether the user is in a particular role.

**How it works:**

1. Before `isUserRole()` is called, the user needs to be authenticated. If the method is called on a user that has not been authenticated, the Container will always return false.
2. The Container takes the `isUserRole()` argument, in this example “Manager”, and compares it to the roles defined for the user in this request.
3. If the user is mapped to this role, the Container returns true.

* We do, however, know of this really nice EJB book...
The declarative side of programmatic security

There’s a good chance that when a programmer hard-codes security role names in a servlet (to use as the argument to isUserInRole()), the programmer was just making up a fake name. He either didn’t know the real role names, or he’s writing a reusable component that’ll be used by more than one company, and those companies aren’t likely to have the exact role names the programmer used. (Of course, if the programmer really wants to build reusable components, hard-coding a role name is a Terrible Idea, but we’ll suspend disbelief for now.)

It turns out that the Deployment Descriptor has a mechanism for mapping hard-coded (which means made-up) role names in a servlet to the “official” <security-role> declarations in your Container.

Imagine, for example, that the programmer used “Manager” as the isUserInRole() argument, but your company uses “Admin” as the <security-role>, and you don’t even have a “Manager” security role. So, even if you can’t stop a programmer from hard-coding a role name, you at least have a work-around when the hard-coded roles don’t match your real role names. Because even if you do have the servlet source code, do you really want to change, recompile, and retest your code just to change every instance of “Manager” to “Admin”?

In the servlet

```java
if( request.isUserInRole("Manager") ) {
  // do the UpdateRecipe page
  ...
} else {
  // do the ViewRecipe page
  ...
}
```

In the DD

```xml
<web-app>
  <servlet>
    <servlet-name>Manager</servlet-name>
  </servlet>
  <security-role-ref>
    <role-name>Admin</role-name>
  </security-role-ref>
</web-app>
```

The Container will use a <security-role-ref> element to map programmatic (hard-coded) role names to declarative <security-role> elements.

*The Container will use a <security-role-ref> element even if the programmatic name matches a “real” <security-role> name.*

When the Container sees an argument to isUserInRole(), it looks first for a matching <security-role-ref>. If it finds one, that’s what it uses, even when the hard-coded name really does match a <security-role> name. Think about it—hard-coding “Manager” in your company, but it might mean something completely different than what the programmer intended. So instead, you might really HAVE a “Manager” security role in your company, but it might be a hard-coded “Director” to “Manager”. So, the <security-role-ref> always wins when both include the same <role-name>.

Assume that NO `<auth-constraint>` is defined.

---

644 chapter 12
Authentication revisited

For a J2EE Container, authentication comes down to this: ask for a user name and password, then verify that they can log in. The first time an unauthenticated user asks for a constrained resource, the Container will automatically start the authentication process. There are four types of authentication the Container can provide, and the main difference between them is, "How securely is the name and password info transmitted?"

The FOUR authentication types

BASIC authentication transmits the login information in an encoded (not encrypted) form. That might sound secure, but you probably already know that since the encoding scheme (base64) is really well known, BASIC provides very weak security.

DIGEST authentication transmits the login information in a more secure way, but because the encryption mechanism isn’t widely used, J2EE containers aren’t required to support it. For more info on DIGEST authentication, check out the IETF RFC 2617 (www.ietf.org/rfc/rfc2617.txt).

CLIENT-CERT authentication transmits the login information in an extremely secure form, using Public Key Certificates (PKC). The downside to this mechanism is that your clients need to have a certificate before they can login to your system. It’s fairly rare for consumers to have a certificate, so CLIENT-CERT authentication is used mainly in business to business scenarios.

The three types above—BASIC, DIGEST, and CLIENT-CERT—all use the browser’s standard pop-up form for inputting the name and password. But the fourth type, FORM, is different.

FORM authentication lets you create your own custom login form out of anything that’s legal HTML. But... of all four types, the form-based info is transmitted in the least secure way. The username and password are sent back in the HTTP request, with no encryption.
Implementing Authentication

This is the simple part—simply declare the authentication scheme in the DD. The main DD element for authentication is `<login-config>.

Four `<login-config>` examples:

- `<login-config>
  <auth-method>BASIC</auth-method>
</login-config>

- `<login-config>
  <auth-method>DIGEST</auth-method>
</login-config>

- `<login-config>
  <auth-method>CERT</auth-method>
</login-config>

- `<login-config>
  <auth-method>FORM</auth-method>
  <form-login-page>/loginPage.html</form-login-page>
  <form-error-page>/loginError.html</form-error-page>
</login-config>`

Except for FORM, once you’ve declared the `<login-config>` element in the DD, implementing Authentication is done! (Assuming you’ve already configured username/password/role info into your server.)
**Form-Based Authentication**

Although there’s more to implementing it than with the *other* forms of authentication, FORM-based isn’t that bad. First, you create your own custom HTML form for the user login (although this can certainly be generated by a JSP). Then you create a custom HTML error page for the Container to use when the user makes a login error. Finally, you tie the two forms together in the DD, using the `<login-config>` element. Note: if you’re using Form-based authentication, be sure to turn on SSL or session tracking, or your Container might not recognize the login form when it’s returned!

**What YOU do:**
1. Declare `<login-config>` in the DD
2. Create an HTML login form
3. Create an HTML error form

   **In the DD...**
   ```xml
   <login-config>
     <auth-method>FORM</auth-method>
   </login-config>
   ```

   **Inside the LoginPage.html...**
   ```html
   <form method="POST" action="/j_security_check">
     <input type="text" name="j_username">
     <input type="password" name="j_password">
     <input type="submit" value="Enter">
   </form>
   ```

   **Inside the loginError.html...**
   ```html
   <html>
   Sorry dude, wrong password
   </body>
   ```

   Three entries in the HTML login form are the key to communicating with the container:
   - `j_security_check`
   - `j_username`
   - `j_password`

   **For the container to work, the action of the HTML login form MUST be `j_security_check`**

   **The Container requires that the HTTP request will store the user name in `j_username`**

   **The Container requires that the HTTP request will store the password in `j_password`**

   **Don’t relax! You need to know everything on this page for the exam!**
**Summary of Authentication types**

This table summarizes key attributes of the four authentication types. "Spec" refers to whether this type of authentication mechanism is defined in the HTTP spec or the J2EE spec. (Hint: you'll need to remember this table when you take the exam.)

<table>
<thead>
<tr>
<th>Type</th>
<th>Spec</th>
<th>Data Integrity</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>BASIC</td>
<td>HTTP</td>
<td>Base64 - weak</td>
<td>HTTP standard, all browsers support it</td>
</tr>
<tr>
<td>DIGEST</td>
<td>HTTP</td>
<td>Stronger - but not SSL</td>
<td>Optional for HTTP and J2EE containers</td>
</tr>
<tr>
<td>FORM</td>
<td>J2EE</td>
<td>Very weak, no encryption</td>
<td>Allows a custom login screen</td>
</tr>
<tr>
<td>CLIENT-CERT</td>
<td>J2EE</td>
<td>Strong - public key, (PKC)</td>
<td>Strong, but users must have certificates</td>
</tr>
</tbody>
</table>

**Data Integrity** refers to the degree to which an eavesdropper can steal or tamper with the information. In a moment, we’ll talk about how to implement data integrity and confidentiality during login.

Data integrity means that the data that arrives is the same as the data that was sent. In other words, nobody tampered with it along the way. Data confidentiality means that nobody else can see the data along the way. Most of the time, though, we treat data integrity and confidentiality as a single goal—things you do to protect data during transmission.

**Q:** What does data integrity have to do with Authentication?

**A:** When you’re authenticating a user, she’s sending you her username and password. Data integrity and confidentiality refers to the degree to which an eavesdropper can steal or tamper with this information. In a moment, we’ll talk about how to implement data integrity and confidentiality during login.

Data integrity means that the data that arrives is the same as the data that was sent. In other words, nobody tampered with it along the way. Data confidentiality means that nobody else can see the data along the way. Most of the time, though, we treat data integrity and confidentiality as a single goal—things you do to protect data during transmission.

```html
<login-config>
  <auth-method>
  <form-login-config>
    <login-page>
      loginPage.html
    </login-page>
  </form-login-config>
  <error-page>
    loginError.html
  </error-page>
</login-config>

<!-- HTML -->
<form method="POST" action="login-config">
  <input type="text" name="username">
  <input type="password" name="j_password">
  <input type="submit" value="Enter">
</form>
```
Form-based authentication doesn’t have any protection for the data. But I don’t want to use the ugly browser login window that the other three authentication types use. Oh if only there were a way to use my own custom login form, but still protect the username and password when they’re sent back.

She doesn’t know about J2EE’s "protected transport layer connection"

Don’t Panic. You can have your custom login cake and secure it too. Login data is still data, so you can secure it in the same way you’d want to protect an online shopper’s credit card number—using your J2EE-compliant Container’s data integrity and confidentiality features.
Securing data in transit: HTTPS to the rescue

When you tell a JEE Container that you want to implement data confidentiality and/or integrity, the JEE spec guarantees that the data to be transmitted will travel over a “protected transport layer connection”. In other words, Containers are not required to use any specific protocol to handle secure transmissions, but in practice they nearly all use HTTPS over SSL.

HTTP request—not secured

A secured HTTPS over SSL request

The Bad Eavesdropper gets a copy of the HTTP request that contains the client’s credit card info. The data isn’t protected, so it comes over in the body of the POST in a nice readable form. The Eavesdropper is happy.

But because it was sent with extra-strength HTTPS over SSL, he CANNOT read the information!!
Chapter 12. Keep it secret, keep it safe

Do you need for every request and response to be secure? If not, which parts of your app need protected transmissions?

What do you think data confidentiality means?

What do you think data integrity means?

If you could apply transmission security measures to only some requests and responses, how would you want to tell the Container which requests and responses?

Can you think of any other DD elements that work on the same level of granularity that you want for declaring protected transmissions?

Think about what's been covered in this chapter. If your web application is going to be fast, efficient and secure, you’ve got some questions to answer... (there are no answers for this one; it's for you to figure out).
How to implement data confidentiality and integrity sparingly and declaratively

Once again, we turn to the DD. In fact, we’ll use our old friend <security-constraint> for both confidentiality and integrity by adding an element called <user-data-constraint>. And when you think about it, it makes sense—if you’re thinking about authorization for a resource, you’re probably going to consider whether you want the data transmitted securely.

```xml
<security-constraint>
  <web-resource-collection>
    <web-resource-name>Recipes</web-resource-name>
    <url-pattern>/Beer/UpdateRecipes/*</url-pattern>
    <http-method>POST</http-method>
  </web-resource-collection>
  <auth-constraint>
    <role-name>Member</role-name>
  </auth-constraint>
  <user-data-constraint><transport-guarantee>CONFIDENTIAL</transport-guarantee></user-data-constraint>
</security-constraint>
```

Put these three sub-elements together to read:

Only Members can make POST requests to resources found in the UpdateRecipes directory, and make sure the transmission is secure.

Legal values for <transport-guarantee>

**NONE**
This is the default, and it means there’s no data protection.

**INTEGRAL**
The data must not be changed along the way.

**CONFIDENTIAL**
The data must not be seen by anybody along the way.

NOTE: although not guaranteed by the spec, in practice virtually every Container uses SSL for guaranteed transport, which means that both INTEGRAL and CONFIDENTIAL do the same thing—either one gives you both confidentiality and integrity. Since you can have only one <user-data-constraint> per <security-constraint>, some people recommend you use CONFIDENTIAL, but again, it will probably never matter in practice, unless you move to a new (and unusual) Container that doesn’t use SSL.
Protecting the request data

Remember that in the DD, the <security-constraint> is about what happens after the request. In other words, the client has already made the request when the Container starts looking at the <security-constraint> elements to decide how to respond. The request data has already been sent over the wire. How can you possibly remind the browser that, “Oh, by the way... if the user happens to request this resource, switch to secure sockets (SSL) before sending the request.”

What can you do?
You already know how to force the client to get a login screen—by defining a constrained resource in the DD, the Container will automatically trigger the authentication process when an unauthenticated user makes the request.

So now we have to figure out how to protect the data coming in from a request... even (and sometimes especially) when the client has not yet logged in.
We might want to protect their login data!

Turn the page to see how it all works...
**Unauthorized client requests a constrained resource that has NO transport guarantee**

1. Client requests `/BuyStuff.jsp`, which has been configured in the DD with a `<security-constraint>`, HTTP over TCP.

   - POST `/BuyStuff.jsp`
   - User-data-constraint: Basic realm = "user"

2. The Container sends a 401 response to the client, that tells the browser to get login information from the user.

   - 401 Unauthorized
   - WWW-Authenticate: Basic realm = "user"

3. The browser makes the same request again, but this time with the user’s login information in the header.

   - POST `/BuyStuff.jsp` Authorization: Basic: "dW3..."

4. The Container authenticates the client (checks that username and password match the user data configured in the server). Then the Container authorizes the request to make sure that this user is in a role that’s allowed to get the constrained resource. Everything checks out, so the response is sent.

   - `<html>`
   - Enter Credit Card #
   - `<input type="text" name="ccNum">`

---

Chapter 12. Keep it secret, keep it safe
Unauthorized client requests a constrained resource that has a CONFIDENTIALITY transport guarantee

1. Client requests /BuyStuff.jsp, a constrained resource that also has a transport guarantee.

   HTTP over TCP
   POST /BuyStuff.jsp HTTP
   container

2. The Container sends a 301 response to the client, that tells the browser to redirect the request using a secure transport.

   301 Redirect
   Location:HTTPS://...
   container

3. The browser makes the same resource request again, but this time, over a secure connection.
   In other words, the resource stays the same, but the protocol is now HTTPS.

   POST /BuyStuff.jsp HTTP
   container

4. Now the Container sees that the resource is constrained, and that this user has not authenticated.
   So now the Container starts the authentication process by sending a '401' to the browser...

   401 Unauthorized
   WWW-Authenticate: basic realm="user"
   container

5. The browser makes the same request again, (yes, for the THIRD time) but this time the request has the user's login data in the header AND the request comes over using a secure connection.
   So this time the client's login data is transmitted securely!

   POST /BuyStuff.jsp
   Authorization: Basic xSw3.=
   container

Redistribution or other use that violates the fair use privilege under U.S. copyright laws (see 17 USC107) or that otherwise violates the Safari Terms of Service is strictly prohibited.
Q: I don’t understand why the Container sends back a REDIRECT (301) to the client when the request comes in without a secure connection. Doesn’t it just redirect back to the same original request?

A: Normally you think of a redirect as meaning “Hey browser, go to a different URL instead.” The redirect is invisible to the client, remember; the client’s browser automatically makes the new request on the URL specified in the redirect (301) header that comes from the server.

But with transport security, it’s a little different. Instead of telling the client’s browser, “Redirect to a different resource,” the Container says, “Redirect to the same resource, but with a different protocol—use HTTPS instead of HTTP.”

Q: So, is HTTPS over SSL just built-in to the Container somehow?

A: It’s not guaranteed by the spec, but it’s extremely likely that your Container is using HTTPS over SSL (secure sockets). But it won’t necessarily be automatic. You probably have to configure SSL in your Container, and more importantly—you need a certificate!

You’ll have to check your Container’s documentation, but chances are, your Container can generate a certificate that you can use for testing, but for production, you’ll need to get a Public Key certification from an “official” source such as VeriSign.

(Certificates and security protocols like HTTPS and SSL are way outside the scope of the exam, by the way. You’re expected to know only what you have to do in the IO, and why. You’re not expected to be the sys-admin and network security master.)
web app security

Configure the security aspects of a web application by filling in the three blocks in the DD. The web application must have the following behavior:

You want anyone to be able to do a GET on the resources within the BeerUpdateRecipes directory (including any subdirectories), but you want ONLY those with the security role of "Admin" to be able to do a POST on resources within that directory. Also, you want the data to be protected so that nobody can eavesdrop.

<web-app...>

<security-constraint>

</security-constraint>

...<security-constraint>

</web-app>
### security exercise

Fill out the following table by writing in the relevant DD elements. You’ll see the answers when you turn the page (and don’t even LOOK at the opposite page!).

<table>
<thead>
<tr>
<th>Security goal</th>
<th>What you’d put in the DD</th>
</tr>
</thead>
<tbody>
<tr>
<td>You want the Container to do BASIC authentication automatically.</td>
<td></td>
</tr>
<tr>
<td>You want to use your own custom form page, named “loginPage.html” (and</td>
<td></td>
</tr>
<tr>
<td>deployed directly at the root of the web app), and you want “loginError.html”</td>
<td></td>
</tr>
<tr>
<td>to be displayed if the client cannot be authenticated.</td>
<td></td>
</tr>
<tr>
<td>You want to constrain everything with a “.do” extension so that all clients</td>
<td></td>
</tr>
<tr>
<td>can do a GET, but only Members can do a POST.</td>
<td></td>
</tr>
<tr>
<td>(You do NOT need to include the DD elements needed to configure login</td>
<td></td>
</tr>
<tr>
<td>information.)</td>
<td></td>
</tr>
<tr>
<td>You want to constrain everything within the foo/bar directory so that only</td>
<td></td>
</tr>
<tr>
<td>those with a security role of Admin can invoke ANY HTTP methods on those</td>
<td></td>
</tr>
<tr>
<td>resources.</td>
<td></td>
</tr>
<tr>
<td>(You do NOT need to include the DD elements needed to configure login</td>
<td></td>
</tr>
<tr>
<td>information.)</td>
<td></td>
</tr>
</tbody>
</table>

---

Chapter 12. Keep it secret, keep it safe
ANSWERS

You want everyone to be able to do a GET on the resources within the
Beer/UpdateRecipes directory (including any subdirectories), but you want
ONLY those with the security role of "Admin" to be able to do a POST on
resources within that directory. Also, you want the data to be protected so
that nobody can eavesdrop.

```
<web-app...>

<security-constraint>

  <web-resource-collection>
  <web-resource-name>Recipes</web-resource-name>
  <url-pattern>/Beer/UpdateRecipes/*</url-pattern>
  <http-method>POST</http-method>
  </web-resource-collection>

<auth-constraint>
  <role-name>Admin</role-name>
</auth-constraint>

<user-data-constraint>
  <transport-guarantee>CONFIDENTIAL</transport-guarantee>
</user-data-constraint>

<security-constraint>
  <web-resource-collection>
  <web-resource-name>Recipes</web-resource-name>
  <url-pattern>/Beer/UpdateRecipes/*</url-pattern>
  <http-method>POST</http-method>
  </web-resource-collection>

<auth-constraint>
  <role-name>Admin</role-name>
</auth-constraint>

<user-data-constraint>
  <transport-guarantee>CONFIDENTIAL</transport-guarantee>
</user-data-constraint>

...  
```

Remember, the URL pattern for protected directories needs to end with a "/".

If you didn’t specify ANY <auth-constraint>, EVERYONE would be able to do a POST.
Putting in Admin means that only Admin can access the combination of the URL pattern
and the HTTP Method.

You could have said INTEGRAL here and for virtually all Containers, you’d still get confidentiality, because Containers use SSL
for their transport guarantee (although that’s not guaranteed by the spec).
### security exercise answers

**Sharpen your pencil**

#### ANSWERS

<table>
<thead>
<tr>
<th>Security goal</th>
<th>What you'd put in the DD</th>
</tr>
</thead>
</table>
| You want the Container to do BASIC authentication automatically. | `<web-app>...
   ...<login-config>
   <auth-method>BASIC</auth-method>
   </login-config>
   </web-app>` |

You want to use your own custom form page, named `loginPage.html` (and deployed directly at the root of the web app), and you want `LoginError.html` to be displayed if the client cannot be authenticated.  

```
<web-app>...
   ...
   <login-config>
     <auth-method>FORM</auth-method>
     <form-login-config>
       <form-login-page>/loginPage.html</form-login-page>
       <form-error-page>/LoginError.html</form-error-page>
     </form-login-config>
   </login-config>
   </web-app>
```

You want to constrain everything with a `do` extension so that all clients can do a GET, but only Members can do a POST. 

```
<web-app>...
   ...<security-constraint>
     <web-resource-collection>
       <web-resource-name>CoolThings</web-resource-name>
       <url-pattern>*.do</url-pattern>
       <http-method>POST</http-method>
     </web-resource-collection>
     <auth-constraint>
       <role-name>Member</role-name>
     </auth-constraint>
   </security-constraint>
   </web-app>
```

You want to constrain everything within the `foo/bar` directory so that only those with a security role of `Admin` can invoke any HTTP methods on those resources.  

```
<web-app>...
   ...<security-constraint>
     <web-resource-collection>
       <web-resource-name>Stuff</web-resource-name>
       <url-pattern>/foo/bar/*</url-pattern>
     </web-resource-collection>
     <auth-constraint>
       <role-name>Admin</role-name>
     </auth-constraint>
   </security-constraint>
   </web-app>
```

Mock Exam Chapter 12

1 Which security mechanisms always operate independently of the transport layer? (Choose all that apply.)
   A. authorization
   B. data integrity
   C. authentication
   D. confidentiality

2 Given a deployment descriptor with three valid <security-constraint> elements, all constraining web resource A. whose respective <auth-constraint> sub-elements are:

   <auth-constraint>Bob</auth-constraint>
   <auth-constraint/>
   <auth-constraint>Alice</auth-constraint>

Who can access resource A?
   A. no one
   B. anyone
   C. only Bob
   D. only Alice
   E. only Bob and Alice
   F. anyone but Bob or Alice
web app  security

Sharpen your pencil

Configure the security aspects of a web application by filling in the three blocks in the DD. The web application must have the following behavior:

You want anyone to be able to do a GET on the resources within the Book/UpdateRecipes directory (including any subdirectories), but you want ONLY those with the security role of “Admin” to be able to do a POST on resources within that directory. Also, you want the data to be protected so that nobody can eavesdrop.

<web-app...>

<security-constraint>

...  

</security-constraint>

...  

</web-app>
Which security mechanisms can be implemented by using a method in the `HttpServletResponse` interface? (Choose all that apply.)

- A. authorization
- B. data integrity
- C. authentication
- D. confidentiality

Which `HttpServletResponse` method is most closely associated with the use of the `<security-role-ref>` element?

- A. getHeader
- B. getHeader
- C. isUserInRole
- D. getUserPrincipal
- E. isRequestedSessionIDValid

Which deployment descriptor elements can contain a `<transport-guarantee>` sub-element? (Choose all that apply.)

- A. <auth-constraint>
- B. <security-role-ref>
- C. <form-login-config>
- D. <user-data-constraint>

Which authentication mechanism is recommended to be used only if cookies or SSL session tracking is in place?

- A. HTTP Basic Authentication
- B. Form Based Authentication
- C. HTTP Digest Authentication
- D. HTTPS Client Authentication
Which security mechanisms always operate independently of the transport layer? (Choose all that apply.)

- A. authorization
- B. data integrity
- C. authentication
- D. confidentiality

Given a deployment descriptor with three valid `<security-constraint>` elements, all constraining web resource A, whose respective `<auth-constraint>` sub-elements are:

- `<auth-constraint>`Bob</auth-constraint>
- `<auth-constraint/>`
- `<auth-constraint>`Alice</auth-constraint>

Who can access resource A?

- A. no one
- B. anyone
- C. only Bob
- D. only Alice
- E. only Bob and Alice
- F. anyone but Bob or Alice
mock answers

3. Which activities would be addressed via a J2EE 1.4 container’s data integrity mechanism? (Choose all that apply.)
   - A. Verifying that a specific user is allowed access to a specific HTML page.
   - B. Ensuring that an eavesdropper can’t read an HTTP message being sent from the client to the container.
   - C. Verifying that a client making a request for a constrained JSP has the proper role credentials to access the JSP.
   - D. Ensuring that a hacker can’t alter the contents of an HTTP message while it is in transit from the container to a client.

   - Option D is correct. This would typically be accomplished through the use of HTTPS. (Servlet spec., 12.1)

4. Which are required fields in the login form when using Form Based Authentication? (Choose all that apply.)
   - A. pw
   - B. id
   - C. j_pw
   - D. j_id
   - E. password
   - F. j_password

   - Option F is correct. The user’s password must be stored in a field called j_password. In addition, the user’s name must be stored in j_username. (Servlet spec., 12.5.3)

5. Which authentication types require a specific type of HTML action? (Choose all that apply.)
   - A. HTTP Basic Authentication
   - B. Form Based Authentication
   - C. HTTP Digest Authentication
   - D. HTTPS Client Authentication

   - Option B is correct. For form based authentication to work, the action of the login form must be j_security_check. (Servlet spec., 12.5.3.1)
Which security mechanisms can be implemented by using a method in the HttpServletRequest interface? (Choose all that apply.)

- Option A is correct. The isUserInRole method can be used programmatically, to help determine whether a client’s role is authorized to access a given resource.
- Option C is correct. The getRemoteUser method can be used programmatically, to help determine whether a client has been authenticated.

Which HttpServletRequest method is most closely associated with the use of the <security-role-ref> element?

- Option C is correct. The <security-role-ref> element is used to map roles hardcoded in a servlet to roles declared in the deployment descriptor. The isUserInRole method is used in a servlet to test the contents of <security-role-ref> elements.

Which deployment descriptor elements can contain a <transport-guarantee> sub-element? (Choose all that apply.)

- Option D is correct. A transport-guarantee element is used within a user-data-constraint element to specify whether a web resource collection should be transmitted using a mechanism such as SSL.

Which authentication mechanism is recommended to be used only if cookies or SSL session tracking is in place?

- Option B is correct. Form based login session tracking can be difficult to implement, therefore a separate session tracking mechanism is recommended.

- Option A is correct. HTTP Basic Authentication
- Option B is correct. Form Based Authentication
- Option C is correct. HTTP Digest Authentication
- Option D is correct. HTTPS Client Authentication
13 filters and wrappers

The Power of Filters

Filters let you intercept the request. And if you can intercept the request, you can also control the response. And best of all, the servlet remains clueless. It never knows that someone stepped in between the client request and the Container’s invocation of the servlet’s service() method. What does that mean to you? More vacations. Because the time you would have spent rewriting just one of your servlets can be spent instead writing and configuring a filter that has the ability to affect all of your servlets. Want to add user request tracking to every servlet in your app? No problem. Want to manipulate the output from every servlet in your app? No problem. And you don’t even have to touch the servlet code. Filters may be the most powerful web app development tool you have.

this is a new chapter 669
Chapter 13. The Power of Filters

official Sun exam objectives

OBJECTIVES

Filters

3.3 Describe the Web Container request processing model: write and configure a filter; create a request or response wrapper; and given a design problem, describe how to apply a filter or wrapper.

Coverage Notes:

This objective is covered completely in this chapter.

11.1 Given a scenario description with a list of issues, select a pattern that would solve the issues. The list of patterns you must know are: Interception Filter, Model-View-Controller, Front Controller, Service Locator, Business Delegate, and Transfer Object.

11.1 Match design patterns with statements describing potential benefits that accrue from the use of the pattern, for any of the following patterns: Interception Filter, Model-View-Controller, Service Locator, Business Delegate, and Transfer Object.

Filters, which are covered in this chapter, are an example of (imagine this) the Intercepting Filter pattern. We don’t cover pattern-specific info until the Patterns chapter, but it’s in THIS chapter where you actually see a design that demonstrates the Intercepting Filter pattern.

670 chapter 13
Enhancing the entire web application

Sometimes you need to enhance your system in ways that span many different use cases or requests. For example, you might want to keep track of your system’s response times, across all of its different user interactions.

I got good news and bad news today. The good news is that the new “Add your favorite recipe” feature on the Beer site is very popular! The bad news is that the boss wants us to keep track of all the users who access these servlets...

I sure don't want to go modify a bunch of working servlets, especially when I know that as soon as I add user tracking, the boss will tell me to take it out again...

Chapter 13. The Power of Filters

request and response filters

How about some kind of “filter”?  

Filters are Java components—very similar to servlets—that you can use to intercept and process requests before they are sent to the servlet, or to process responses after the servlet has completed, but before the response goes back to the client.

The Container decides when to invoke your filters based on declarations in the DD. In the DD, the deployer maps which filters will be called for which request URL patterns. So it’s the deployer, not the programmer, who decides which subset of requests or responses should be processed by which filters.

Fun things to do with Filters

Request filters can:

- perform security checks
- reformat request headers or bodies
- audit or log requests

Response filters can:

- compress the response stream
- append or alter the response stream
- create a different response altogether

There is only ONE filter interface, Filter.

There’s no such thing as a RequestFilter or ResponseFilter interface—it’s just Filter. When we talk about a request filter vs. a response filter, we’re talking only about how you USE the filter, not the actual filter interface. As far as the Container is concerned, there is only one kind of filter—anything that implements the Filter interface.
Filters are modular, and configurable in the DD

Filters can be chained together, to run one after the other. Filters are designed to be totally self-contained. A filter doesn’t care which (if any) filters ran before it did, and it doesn’t care which one will run next.*

The DD controls the order in which filters run; we’ll talk about filter DD configuration a little later in the chapter.

**DD configuration 1:**

Using the DD, you can link them together by telling the Container: “For these URLs, run filter 1, then filter 7, then filter 3, then run the target servlet.”

```
Client ➔ Container ➔ Filter 1 ➔ Filter 7 ➔ Filter 3 ➔ Servlet
```

**DD configuration 2:**

Then, with a quick change to the DD, you can delete and swap them with: “For these URLs, run filter 3, then filter 7, and then the target servlet.”

```
Client ➔ Container ➔ Filter 1 ➔ Filter 3 ➔ Filter 7 ➔ Servlet
```

* We’re fudging a little. The deployer often does need to configure the order based on the consequences of the transformations performed by the filters. You wouldn’t, for example, add a watermark to an image after you applied a compression filter. In that example, the watermark filter would have to do its thing before the data hits the compression filter. The point is, you as the programmer will not build dependencies into your code.
Three ways filters are like servlets

Kim’s right, filters live in the Container. In many ways they’re similar to their co-residents, servlets. Here are a few ways in which filters are like servlets:

The Container knows their API

Filters have their own API. When a Java class implements the Filter interface, it’s striking a deal with the Container, and it goes from being a plain old class to being an official J2EE Filter. Other members of the filter API allow filters to get access to the ServletContext, and to be linked to other filters.

The Container manages their lifecycle

Just like servlets, filters have a lifecycle. Like servlets, they have init() and destroy() methods. Similar to a servlet’s doGet() doPost() method, filters have a doFilter() method.

They’re declared in the DD

A web app can have lots of filters, and a given request can cause more than one filter to execute. The DD is the place where you declare which filters will run in response to which requests, and in which order.
Building the request tracking filter

Our task is to enhance the Beer application so that whenever someone requests any of the resources associated with updating recipes, we’ll be able to keep track of who made the request. Here’s one version of what such a filter might look like.

```java
package com.example.web;
import java.io.*;
import javax.servlet. *;
import javax.servlet.http.HttpServletRequest;
public class BeerRequestFilter implements Filter {
    private FilterConfig fc;
    public void init(FilterConfig config) throws ServletException {
        this.fc = config;
    }
    public void doFilter(ServletRequest req,
            ServletResponse resp,
            FilterChain chain) throws ServletException, IOException {
        HttpServletRequest httpReq = (HttpServletRequest) req;
        String name = httpReq.getRemoteUser();
        if (name != null) {
            fc.getServletContext().log("User " + name + " is updating");
        }
        chain.doFilter(req, resp);
    }
    public void destroy() {
        // do cleanup stuff
    }
}
```

You must implement destroy(), but usually it’s empty.
A filter’s life cycle

Every filter must implement the three methods in the Filter interface: `init()`, `doFilter()`, and `destroy()`.  

**First there’s init()**

When the Container decides to instantiate a filter, the `init()` method is your chance to do any setup tasks before the filter is called. The most common implementation was shown on the previous page: saving a reference to the `FilterConfig` object for later use in the filter.

**doFilter() does the heavy lifting**

The `doFilter()` method is called every time the Container determines that the filter should be applied to the current request. The `doFilter()` method takes three arguments:

- A `ServletRequest`
  (not an `HttpServletRequest`!)
- A `ServletResponse`
  (not an `HttpServletResponse`!)
- A `FilterChain`

The `doFilter()` method is your chance to implement your filter’s function. If your filter is supposed to log user names to a file, do it in `doFilter()`. Want to compress the response output? Do it in `doFilter()`.

**In the end there’s destroy()**

When the Container decides to remove a filter instance, it calls the `destroy()` method, giving you a chance to do any cleanup you need to do before the instance is destroyed.

**Dumb Questions**

**Q:** What is a `FilterChain`?

**A:** A `FilterChain` is the coolest thing in all of Filter-dom. Filters are designed to be modular building blocks you can mix together in a variety of ways to make a combination of things happen, and the `FilterChain` is a big part of what makes this possible. It’s the thing that knows what comes next. We already mentioned that the filters (not to mention the servlet) shouldn’t know anything about the other filters involved in the request... but someone needs to know the order, and that someone is the `FilterChain`, driven by the filter elements you specify in the DD.

By the way, `FilterChain` is in the same package as `Filter, javax.servlet`.

**Q:** I noticed that in your `doFilter()` method you made this call: `chain.doFilter(...)`. What’s a `doFilter()` doing inside a `doFilter()`? You’re not gonna get all recursive on us, are you?

**A:** The `FilterChain` interface’s `doFilter()` is a little bit different than the `Filter` interface’s `doFilter()`.

Here’s the main difference:

The `doFilter()` method of the `FilterChain` takes care of figuring out whose `doFilter()` method to invoke next (or, if it’s the end of the chain, which servlet’s service() method). The `doFilter()` method in a filter actually does the filtering—the thing the filter was created to do.

This means a `FilterChain` can invoke EITHER a filter or a servlet, depending on whether it’s the end of the chain. The end of the chain is always either a servlet or a JSP (which means a JSP’s generated servlet, of course), assuming the Container is able to map the request URL to a servlet or JSP. (If the Container can’t locate the right resource for the request, the filter is never invoked.)
Think of filters as being "stackable"

The servlet spec doesn’t dictate how the `chain.doFilter(req, resp)` method is handled inside the container. In practice, though, you can think of the process of filters chaining to each other as if they were simply method calls on a single stack. We know there’s more going on behind the scenes in the Container, but we don’t care, as long as we can predict how our filters will run, and a conceptual (if not physical) stack lets us do that.

A conceptual call stack example

In this example, a request for ServletA will be filtered by two filters, Filter5, then Filter7.

1. Upon getting the request, the Container calls Filter3’s `doFilter()` method, which runs until it encounters its chain `doFilter()` call.
2. The Container pushes Filter7’s `doFilter()` method on the top of the stack - where it executes until it reaches its chain `doFilter()` call.
3. The Container returns control to Filter7, where its `doFilter()` method completes and is then popped off the stack.
4. The Container returns control to Filter3, where its `doFilter()` method completes, and is then popped off. Then the Container completes the response.
configuring filters

Declaring and ordering filters

When you configure filters in the DD, you’ll usually do three things:

- Declare your filter
- Map your filter to the web resources you want to filter
- Arrange these mappings to create filter invocation sequences

Declaring a filter

```xml
<filter>
  <filter-name>BeerRequest</filter-name>
  <filter-class>com.example.web.BeerRequestFilter</filter-class>
  <init-param>
    <param-name>LogFileName</param-name>
    <param-value>UserLog.txt</param-value>
  </init-param>
</filter>
```

Rules for `<filter>`

- The `<filter-name>` is mandatory.
- The `<filter-class>` is mandatory.
- The `<init-param>` is optional, and you can have many.

Declaring a filter mapping to a URL pattern

```xml
<filter-mapping>
  <filter-name>BeerRequest</filter-name>
  <url-pattern>*.do</url-pattern>
</filter-mapping>
```

Rules for `<filter-mapping>`

- The `<filter-name>` is mandatory and it is used to link to the correct `<filter>` element.
- Either the `<url-pattern>` or the the `<servlet-name>` element is mandatory.
- The `<url-pattern>` element defines which web app resources will use this filter.

Declaring a filter mapping to a servlet name

```xml
<filter-mapping>
  <filter-name>BeerRequest</filter-name>
  <servlet-name>AdviceServlet</servlet-name>
</filter-mapping>
```

- The `<servlet-name>` element defines which single web app resource will use this filter.

IMPORTANT: The Container’s rules for ordering filters:

When more than one filter is mapped to a given resource, the Container uses the following rules:

1) ALL filters with matching URL patterns are located first. This is NOT the same as the URL mapping rules the Container uses to choose the “winner” when a client makes a request for a resource, because ALL filters that match will be placed in the chain! Filters with matching URL patterns are placed in the chain in the order in which they are declared in the DD.

2) Once all filters with matching URLs are placed in the chain, the Container does the same thing with filters that have a matching `<servlet-name>` in the DD.
News Flash: As of version 2.4, filters can be applied to request dispatchers

Think about it. It’s great that filters can be applied to requests that come directly from the client. But what about resources requested from a forward or include. request dispatch, and/or the error handler? Servlet spec 2.4 to the rescue.

Declaring a filter mapping for request-dispatched web resources

```xml
<filter-mapping>
  <filter-name>MonitorFilter</filter-name>
  <url-pattern>*.do</url-pattern>
  <dispatcher>REQUEST</dispatcher>
  - and / or -
  <dispatcher>INCLUDE</dispatcher>
  - and / or -
  <dispatcher>FORWARD</dispatcher>
  - and / or -
  <dispatcher>ERROR</dispatcher>
</filter>
```

Declaration Rules

- The `<filter-name>` is mandatory.
- Either the `<url-pattern>` or `<servlet-name>` element is mandatory.
- You can have from 0 to 4 `<dispatcher>` elements.
- A REQUEST value activates the filter for client requests. If no `<dispatcher>` element is present, REQUEST is the default.
- An INCLUDE value activates the filter for request dispatching from an include() call.
- A FORWARD value activates the filter for request dispatching from a forward() call.
- An ERROR value activates the filter for resources called by the error handler.
**filter configuration exercise**

Based on the following DD fragment, write down the sequence in which the filters will be executed for each request path. Assume Filter1 through Filter5 have been properly declared. (Answers are at the end of this chapter.)

```
<filter-mapping>
  <filter-name>Filter1</filter-name>
  <url-pattern>/Recipes/*</url-pattern>
</filter-mapping>

<filter-mapping>
  <filter-name>Filter2</filter-name>
  <servlet-name>/Recipes/HopsList.do</servlet-name>
</filter-mapping>

<filter-mapping>
  <filter-name>Filter3</filter-name>
  <url-pattern>/Recipes/Add/*</url-pattern>
</filter-mapping>

<filter-mapping>
  <filter-name>Filter4</filter-name>
  <servlet-name>/Recipes/Modify/ModRecipes.do</servlet-name>
</filter-mapping>

<filter-mapping>
  <filter-name>Filter5</filter-name>
  <url-pattern>/</url-pattern>
</filter-mapping>
```

<table>
<thead>
<tr>
<th>Request path</th>
<th>Filter Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>/Recipes/HopsReport.do</td>
<td>Filters:</td>
</tr>
<tr>
<td>/Recipes/HopsList.do</td>
<td>Filters:</td>
</tr>
<tr>
<td>/Recipes/Modify/ModRecipes.do</td>
<td>Filters:</td>
</tr>
<tr>
<td>/HopsList.do</td>
<td>Filters:</td>
</tr>
<tr>
<td>/Recipes/Add/AddRecipes.do</td>
<td>Filters:</td>
</tr>
</tbody>
</table>
Compressing output with a response-side filter

Earlier we showed a very simple request filter. But now we’ll look at a response filter. Response filters are a bit trickier, but they can be incredibly useful. They let us do something to the response output after the servlet does its thing, but before the response is sent to the client. So instead of stepping in at the beginning—before the servlet gets the request—we step in at the end—after the servlet gets the request and generates a response.

Well, sort of... think about it. Filters are always invoked in the chain before the servlet. There’s no such thing as a filter that is invoked only after the servlet.

But... remember that stack picture. The filter gets another shot at this after the servlet completes its work and is popped off the (virtual) stack!

My boss liked my first filter so much he wants me to write another one. The company’s pipe to the Internet is getting really busy, so now he wants us to compress all of our response streams...

Seems like a filter would be the way to go... But since we’re dealing with responses, I’ll have to put the compression code AFTER the chain.doFilter() call.
Architecture of a response filter

Rachel is talking about the basic structure of what you put in a doFilter() method—first you do work related to the request, then you call chain.doFilter(), then finally, when the servlet (and any other filter in the chain after your filter) completes and control is returned to your original doFilter() method, you can do something to the response.

Rachel's pseudo-code for the compression filter

class MyCompressionFilter implements Filter {
  init();

  public void doFilter (request, response, chain) {
    // this is where request handling would go
    chain.doFilter(request, response);
    // do compression logic here

    destroy();
  }
}

The conceptual call stack

The Compression filter's doFilter() method runs, and invokes chain.doFilter(). It's too early to do any compression—the goal is to compress the response output from the servlet.

The Servlet's service() method goes on the top of the stack, does some work, generates a response output, and completes.

Now that the Servlet's service() method has popped off the stack, the rest of the compression filter's doFilter() method can run, and (it hopes) do the compression on whatever the servlet wrote to the response output!
But is it really that simple?

Does compressing the response really involve nothing more than waiting for the servlet to finish, then compressing the servlet's response output? After all, the filter’s doFilter() method has a reference to the same response object that went to the servlet, so in theory, the filter should have access to the response output...

```java
public void doFilter(request, response, chain) {
    // this is where request handling would go
    chain.doFilter(request, response);  // 1, 2
    // do compression logic here  // 3
}
```

1. The filter passes the request and response to the servlet, and waits patiently for its chance to compress stuff.

2a. The servlet does its thing, creating output, blissfully unaware that this very same output was supposed to be compressed.

2b. The output goes back through the Container and...

2c. It's sent back to the client! Hmm... this could be a problem. The filter was hoping to have a chance to do something to the output (compress it) before the output went to the client.

3. The call to chain.doFilter() has returned, and the filter was hoping to grab the output and and start compressing...

EXCEPT it's too late! The output was already sent to the client! The Container doesn't buffer the output for the filter. By the time the filter's own doFilter() method is at the top of the (conceptual) stack, it's too late for the filter to affect the output.
filtering the output

The output has left the building

This won’t work! I can’t compress something on the way out of the servlet, because it’s too late. The output goes straight from the servlet back to the client. But the whole point is to compress the output, so how can I get control of the output BEFORE it goes to the client?

Think about this for a minute... the servlet actually gets the output stream or writer from the response object. What if instead of passing the REAL response object to the servlet, your filter swapped in a custom response object with an output stream that you control? Nobody said the filter has to pass the REAL response when it calls chain.doFilter()...

Original request and response

doFilter(

A DIFFERENT response

chain.doFilter(

Container

Filter

Servlet

684 chapter 13
We can implement our OWN response

The Container already implements the HttpServletResponse interface; that’s what you get in the doFilter() and service() methods. But to get this compression filter working, we have to make our own custom implementation of the HttpServletResponse interface and pass that to the servlet via the chain.doFilter() call. And that custom implementation has to also include a custom output stream as well, since that’s the goal—to capture the output after the servlet writes to it but before it goes back to the client.

The "MyResponse" object delegates (passes-through), most of the calls it receives, to the "real" response object. The "MyResponse" object also has a custom output stream that compresses the data written by the servlet, and then sends the compressed data to the original output stream (that goes back to the client).

Q: Filters pass ServletRequest and ServletResponse objects to the next thing in the chain, NOT HttpServlet Response! So why are you talking about implementing HttpServletResponse?

A: Filters were designed to be generic, and so officially, you’re right. If we thought one of our filters might be used in a non-web app, we’d be implementing the non-HTTP interface (ServletResponse), but today, the chances of someone developing non-HTTP servlets is close to zero, so we’re not worried. And since ServletResponse is the supertype of HttpServletResponse, there’s no problem passing an HttpServletResponse where a ServletResponse is expected.
implementing HttpServletResponse

HttpServletResponse is such a complicated interface... if only there were a way to avoid implementing all those methods and delegating calls to the real response...

She doesn't know about the servlet Wrapper classes

Creating your own custom HttpServletResponse implementation would be a pain. Especially when all you want to implement are just a few of the methods. And since HttpServletResponse is an interface that extends another interface, to implement your own custom response, you'd have to implement everything in both HttpServletResponse and its superinterface, ServletResponse.

But fortunately, someone at Sun did that for you, by creating a support convenience class that implements the HttpServletResponse interface. All of the methods in that class delegate the calls to the underlying real response created by the Container.

Remember, to implement HttpServletResponse you have to implement EVERYTHING from both it and its superinterface ServletResponse.
Wrappers rock

The wrapper classes in the servlet API are awesome—they implement all the methods needed for the thing you’re trying to wrap, delegating all calls to the underlying request or response object. All you need to do is extend one of the wrappers, and override just the methods you need to do your custom work.

You’ve seen support classes in the J2SE API, of course, with things like the Listener adapter classes for GUIs. And you’ve seen them in the JSP API with the custom tag support classes. But while those support classes and these request and response wrappers are all convenience classes, the wrappers are a little different because they, well, wrap an object of the type they implement. In other words, they don’t just provide an interface implementation, they actually hold a reference to an object of the same interface type to which they delegate method calls. (By the way, this has nothing whatsoever to do with the J2SE “primitive wrapper” classes like Integer, Boolean, Double, etc.)

Creating a specialized version of a request or response is such a common approach when creating filters, that Sun has created four “convenience” classes to make the job easier:

- `ServletRequestWrapper`
- `HttpServletRequestWrapper`
- `ServletResponseWrapper`
- `HttpServletRequestWrapper`

Although not explicitly listed in the official objectives, you might see “Decorator” on the exam.

If you’re familiar with regular old (non-J2EE) design patterns, then you probably recognize this wrapper classes as an example of using a Decorator pattern (although it is also sometimes called Wrapper pattern. The Decorator/Wrapper decorates/wraps one kind of an object with an “enhanced” implementation. And by “enhanced”, we mean “adds new capabilities” while still doing everything the original wrapped thing did.

It’s ike saying, “I’m just a BETTER version of the thing I’m wrapping—I do everything it does, and more.” One characteristic of a Decorator/Wrapper is that it delegates method invocations to the thing it wraps, rather than being a complete replacement.
Adding a simple Wrapper to the design

Let's enhance Rachel's first pseudo-code by adding a wrapper.

Compression filter design, version 2 (pseudocode)

```java
class CompressionResponseWrapper extends HttpServletResponseWrapper {
    // override any methods you want to customize
}

class MyCompressionFilter implements Filter {
    public void init(FilterConfig config) { }
    public void doFilter(request, response, chain) {
        CompressionResponseWrapper wrappedResp = new CompressionResponseWrapper(response);
        chain.doFilter(request, wrappedResp);
        // do compression logic here
    }
    public void destroy() { }
}
```

1. The filter passes the request object and a custom response object to the servlet.
2. Since we didn't override any methods in the Wrapper, the output stream isn't affected... yet.
Add an output stream Wrapper

Let’s add a second Wrapper...

```java
class CompressionResponseWrapper extends HttpServletResponseWrapper {
    public ServletOutputStream getOutputStream() throws IOException {
        return new GZipOutputStream(respons.getOutputStream());
    }
    // maybe override other methods
}
```

```java
class MyCompressionFilter implements Filter {
    public void init(FilterConfig cfg) { }
    public void doFilter(ServletRequest request, ServletResponse response, FilterChain chain) {
        CompressionResponseWrapper wrappedResp = new CompressionResponseWrapper(response);
        chain.doFilter(request, wrappedResp);
        // do compression logic here  
    }
    public void destroy() { }
}```

1. The filter passes the request object and a custom response object to the servlet. The custom response has a special getOutputStream method.

2. When the servlet asks for an it doesn’t KNOW that it will get a “special” output stream.
**response compression filter**

### The real compression filter code

Time to code. We end this chapter by looking at the code for both the compression filter and the wrapper it uses. We’re expanding from the previous discussion, and while there is some new stuff here, it’s mostly just plain Java code.

This filter provides a mechanism to compress the response body content. This type of filter would commonly be applied to any text content such as HTML, but not to most media formats such as PNG or MPEG, because they are already compressed.

```java
package com.example.web;

import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;
import java.util.zip.GZIPOutputStream;

public class CompressionFilter implements Filter {

    private ServletContext ctx;
    private FilterConfig cfg;

    public void init(FilterConfig cfg) throws ServletException {
        this.cfg = cfg;
        ctx = cfg.getServletContext();
        ctx.log(cfg.getFilterName() + " initialized.");
    }

    public void doFilter(ServletRequest req, ServletResponse resp, FilterChain fc) throws IOException, ServletException {
        HttpServletRequest request = (HttpServletRequest) req;
        HttpServletResponse response = (HttpServletResponse) resp;

        String valid_encodings = request.getHeader("Accept-Encoding");
        if (valid_encodings.indexOf("gzip") > -1) {
            CompressionResponseWrapper wrappedResp = new CompressionResponseWrapper(response);

            response.setContentType("text/html;charset=UTF-8");
            response.getOutputStream().write("Hello, World!").close();
        }
    }

    public void destroy() {
    }
}
```

This filter provides a mechanism to compress the response body content. The filter uses a Decorator pattern to wrap the output stream with a compression I/O stream. Compression of the output stream is performed if and only if the client includes an Accept-Encoding header (specifically, for gzip). Does the client accept GZIP compression? If so, wrap the response object with a compression wrapper.
Compression filter code, cont.

```
wrappedResp.setHeader("Content-Encoding", "gzip");
fc.doFilter(request, wrappedResp);

GZIPOutputStream gzos = wrappedResp.getOutputStream();
gzos.finish();
ctx.log(cfg.getFilterName() + " : finished the request.");
} else {
    ctx.log(cfg.getFilterName() + " : no encoding performed.");
}

public void destroy()
    // nulling out my instance variables
    cfg = null;
    ctx = null;
}
```

"Off the path"

**Compression meets HTTP**

How does the server know it can send compressed data? How does the browser know when it’s getting compressed data? It turns out that HTTP is "compression-aware"; here’s how it works:

- One of the headers that the browser sends ("Accept-Encoding: gzip"), tells the server about the browser’s capabilities for dealing with different types of content.
- If the server sees that the browser can deal with compressed data, it will perform the compression, and add a header ("Content-Encoding: gzip"), to the response.
- When the browser receives the response, the "Content-Encoding: gzip" header tells the browser to de-compress the data before it is displayed.

---

Chapter 13. The Power of Filters

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher:Prepared for Augusto Jaramillo Forcada, Safari ID: augustojf.cv@gmail.com Print Publication Date: 8/1/2004 User number: 729515 Copyright 2007, Safari Books Online, LLC.

Redistribution or other use that violates the fair use privilege under U.S. copyright laws (see 17 USC107) or that otherwise violates the Safari Terms of Service is strictly prohibited.
response compression wrapper

Compression wrapper code

We looked at the Compression filter; now let’s take a look at the wrapper it uses. This is one of the most complicated topics in all of servlet-dom, so don’t panic if you don’t grok it the first time.

This response wrapper decorates the original response object by adding a compression decorator on the original servlet output stream.

package com.example.web;

// Servlet imports
import javax.servlet.http.*;
import javax.servlet./*;
// I/O imports
import java.io.*;
import java.util.zip.GZIPOutputStream;

class CompressionResponseWrapper extends HttpServletResponseWrapper {
    private GZIPOutputStream servletGzipOS = null;
    private PrintWriter pw = null;

    CompressionResponseWrapper(HttpServletResponse resp) {
        super(resp);
    }

    public void setContentLength(int len) {
        // Ignore this method—the output will be compressed.
    }

    public GZIPOutputStream getGZIPOutputStream() {
        return this.servletGzipOS.internalGzipOS;
    }
}

This decorator method, used by the filter, gives the compression filter a handle on the GZIP output stream so that the filter can “finish” and flush the GZIP stream.

692 chapter 13
Compression wrapper code, cont.

```java
private Object streamUsed = null;

public ServletOutputStream getOutputStream() throws IOException {
    if (streamUsed != null) {
        throw new IllegalStateException();
    }
    if (servletGzipOS == null) {
        servletGzipOS = new GZipServletOutputStream(getResponse().
                getOutputStream());
        streamUsed = servletGzipOS;
    }
    return servletGzipOS;
}

public PrintWriter getWriter() throws IOException {
    if (streamUsed != null) {
        throw new IllegalStateException();
    }
    if (pw == null) {
        servletGzipOS = new GZipServletOutputStream(getResponse().
                getOutputStream());
        OutputStreamWriter osw = new OutputStreamWriter(servletGzipOS, getResponse().
                getCharacterEncoding());
        pw = new PrintWriter(osw);
        streamUsed = pw;
    }
    return pw;
}
```

Provide access to a decorated servlet output stream.

Allow the servlet to access a servlet output stream, only if the servlet has not already accessed the print writer.

Wrap the original servlet output stream with our compression servlet output stream.

To make a print writer, we have to first wrap the servlet output stream and then wrap the compression servlet output stream in two additional output stream decorators: OutputStreamWriter which converts characters into bytes, and then a PrintWriter on top of the OutputStreamWriter object.

you are here  693
**response output** decorator

**Compression wrapper, helper class code**

This helper class is a Decorator on the ServletOutputStream abstract class which delegates the real work of compressing the generated content using a standard GZIP output stream.

There is only one abstract method in the ServletOutputStream that this Decorator must implement: write(int). This is where all of the delegation magic occurs!

```java
class GZIPServletOutputStream extends ServletOutputStream {

  GZIPOutputStream internalGzipOS;

  /* Decorator constructor */
  GZIPServletOutputStream(ServletOutputStream sos) throws IOException {
    this.internalGzipOS = new GZIPOutputStream(sos);
  }

  public void write(int param) throws java.io.IOException {
    internalGzipOS.write(param);
  }
}
```

This method implements the compression decoration by delegating the `write()` call to the GZIP compression stream, which is wrapping the original ServletOutputStream (which in turn is ultimately wrapping the TCP network output stream to the client).

---

Chapter 13. The Power of Filters

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher: Prepared for Augusto Jaramillo Forcada, Safari ID: augustojf.cv@gmail.com

Print Publication Date: 8/1/2004 User number: 729515 Copyright 2007, Safari Books Online, LLC.

This PDF is exclusively for your use in accordance with the Safari Terms of Service. Redistribution or other use that violates the fair use privilege under U.S. copyright laws (see 17 USC107) or that otherwise violates the Safari Terms of Service is strictly prohibited.
Write down the sequence in which the filters will be executed for each request path. Assume Filter1 - Filter5 have been properly declared.

```xml
<filter-mapping>
  <filter-name>Filter1</filter-name>
  <url-pattern>/Recipes/*</url-pattern>
</filter-mapping>

<filter-mapping>
  <filter-name>Filter2</filter-name>
  <servlet-name>/Recipes/HopsList.do</servlet-name>
</filter-mapping>

<filter-mapping>
  <filter-name>Filter3</filter-name>
  <url-pattern>/Recipes/Add/*</url-pattern>
</filter-mapping>

<filter-mapping>
  <filter-name>Filter4</filter-name>
  <servlet-name>/Recipes/Modify/ModRecipes.do</servlet-name>
</filter-mapping>

<filter-mapping>
  <filter-name>Filter5</filter-name>
  <url-pattern>/</url-pattern>
</filter-mapping>
```

<table>
<thead>
<tr>
<th>Request path</th>
<th>Filter Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>/Recipes/HopsReport.do</td>
<td>Filters: 1, 5</td>
</tr>
<tr>
<td>/Recipes/HopsList.do</td>
<td>Filters: 1, 5, 2</td>
</tr>
<tr>
<td>/Recipes/Modify/ModRecipes.do</td>
<td>Filters: 1, 5, 4</td>
</tr>
<tr>
<td>/HopsList.do</td>
<td>Filters: 5</td>
</tr>
<tr>
<td>/Recipes/Add/AddRecipes.do</td>
<td>Filters: 1, 3, 5</td>
</tr>
</tbody>
</table>
Mock Exam Chapter 13

Which are true about filters? (Choose all that apply.)

- A. A filter can act on only the request or response object, not both.
- B. The `destroy` method is always a container callback method.
- C. The `doFilter` method is always a container callback method.
- D. The only way a filter can be invoked is through a declaration in the DD.
- E. The next filter in a filter chain can be specified either by the previous filter or in the DD.

Which are true about declaring filters in the DD? (Choose all that apply.)

- A. Unlike servlets, filters CANNOT declare initialization parameters.
- B. Filter chain order is always determined by the order the elements appear in the DD.
- C. A class that extends an API request or response wrapper class must be declared in the DD.
- D. A class that extends an API request or response wrapper class is using the Interceptor Filter pattern.
- E. Filter chain order is affected by whether filter mappings are declared via `<url-pattern>` or via `<servlet-name>`.

mock exam
Given this method in an otherwise properly defined Filter implementation:

```java
public void doFilter(ServletRequest req, ServletResponse response,
                      FilterChain chain) throws IOException, ServletException {
    HttpServletRequest request = (HttpServletRequest) req;
    HttpSession session = request.getSession();
    Object user = session.getAttribute("user");
    if (user != null) {
        UserRequest ureq = new UserRequest(request, user);
        chain.doFilter(ureq, response);
    } else {
        RequestDispatcher rd = request.getRequestDispatcher("/login.jsp");
        rd.forward(request, response);
    }
```

Which is true?

- A. An exception will always be thrown if line 31 executes.
- B. Line 28 is invalid because request must be passed as the first argument.
- C. This line: `chain.doFilter(request, response)` must be inserted somewhere in the else block.
- D. This method does not properly implement `Filter.doFilter()` because the method signature is incorrect.
- E. None of the above.
mock exam

Given a partial deployment descriptor:

```
<filter>
  <filter-name>My Filter</filter-name>
  <filter-class>com.example.MyFilter</filter-class>
</filter>
<filter-mapping>
  <filter-name>My Filter</filter-name>
  <url-pattern>/my</url-pattern>
</filter-mapping>
<servlet>
  <servlet-name>My Servlet</servlet-name>
  <servlet-class>com.example.MyServlet</servlet-class>
</servlet>
```

Which is true? (Choose all that apply.)

- A. The file is invalid because the URL pattern `/my`
  is mapped to both a servlet and a filter.

- B. The file is invalid because neither the servlet name
  nor the filter name is allowed to contain spaces.

- C. The filter MyFilter will be invoked after the
  MyServlet servlet for each request that matches
  the pattern `/my`.

- D. The filter MyFilter will be invoked before the
  MyServlet servlet for each request that matches
  the pattern `/my`.

- E. The file is invalid because the `<filter>` element must
  contain a `<servlet-name>` element that defines
  which servlet the filter should be applied to.
Chapter 13. The Power of Filters

Which about filters are true? (Choose all that apply.)

- A. Filters may be used to create request or response wrappers.
- B. Wrappers may be used to create request or response filters.
- C. Unlike servlets, all filter initialization code should be placed in the constructor since there is no `init()` method.
- D. Filters support an initialization mechanism that includes an `init()` method that is guaranteed to be called before the filter is used to handle requests.
- E. A filter's `doFilter()` method must call `doFilter()` on the input `FilterChain` object in order to ensure that all filters have a chance to execute.
- F. When calling `doFilter()` on the input `FilterChain`, a filter's `doFilter()` method must pass in the same `ServletRequest` and `ServletResponse` objects that were passed into it.
- G. A filter's `doFilter()` may block further request processing.

Which are true about the servlet Wrapper classes? (Choose all that apply.)

- A. They provide the only mechanism for wrapping `ServletRequest` objects.
- B. They can be used to decorate classes that implement `Filter`.
- C. They can be used even when the application does NOT support HTTP.
- D. The API provides wrappers for `ServletRequest`, `ServletResponse`, and `FilterChain` objects.
- E. They implement the Intercepting Filter pattern.
- F. When you subclass a wrapper class, you must override at least one of the wrapper class's methods.
Which are true about filters? (Choose all that apply.)

- A filter can act on only the request or response object, not both.
- B. The destroy method is always a container callback method.
- C. The doFilter method is always a container callback method.
- D. The only way a filter can be invoked is through a declaration in the DD.
- E. The next filter in a filter chain can be specified either by the previous filter or in the DD.

Which are true about declaring filters in the DD? (Choose all that apply.)

- A. Unlike servlets, filters CANNOT declare initialization parameters.
- B. Filter chain order is always determined by the order the elements appear in the DD.
- C. A class that extends an API request or response wrapper class must be declared in the DD.
- D. A class that extends an API request or response wrapper class is using the Intercepting Filter pattern.
- E. Filter chain order is affected by whether filter mappings are declared via <url-pattern> or via <servlet-name>.

- Option C is incorrect, doFilter is both a callback and an inline method.
- Option E is incorrect, the order of filter execution is always determined in the DD.
- Option B is incorrect, because <url-pattern> mappings will be chained before <servlet-name> mappings.
- Option D is incorrect, wrappers are examples of the Decorator pattern.
Given this method in an otherwise properly defined `Filter` implementation:

```java
20. public void doFilter(ServletRequest req,
21.     ServletResponse response,
22.     FilterChain chain) throws IOException, ServletException {
23.     HttpServletRequest request = (HttpServletRequest) req;
24.     HttpSession session = request.getSession();
25.     Object user = session.getAttribute("user");
26.     if (user != null) {
27.         UserRequest ureq = new UserRequest(request, user);
28.         chain.doFilter(ureq, response);
29.     } else {
30.         RequestDispatcher rd = request.getRequestDispatcher("/login.jsp");
31.         rd.forward(request, response);
32.     }
33. }
```

Which is true?

- Option A is incorrect as it is valid for a filter to forward a request.
- Option B is incorrect because it is valid for a filter to wrap a request (note that UserRequest must implement ServletRequest).
- Option C is incorrect because the `doFilter` method is NOT required to call `chain.doFilter()`.
- Option D is incorrect because the method signature is incorrect.
- Option E is incorrect because the method does not properly implement `Filter.doFilter()`.

E. None of the above.
mock answers

Given a partial deployment descriptor:

4. <filter>
11. <filter-name>My Filter</filter-name>
12. <filter-class>com.example.MyFilter</filter-class>
13. </filter>
15. <filter-mapping>
16. <filter-name>My Filter</filter-name>
17. <url-pattern>/my</url-pattern>
18. </filter-mapping>
19. <servlet>
20. <servlet-name>My Servlet</servlet-name>
21. <servlet-class>com.example.MyServlet</servlet-class>
22. </servlet>
23. <servlet-mapping>
24. <servlet-name>My Servlet</servlet-name>
25. <url-pattern>/my</url-pattern>
26. </servlet-mapping>

Which is true? (Choose all that apply.)

- A. The file is invalid because the URL pattern /my is mapped to both a servlet and a filter.

- B. The file is invalid because neither the servlet name nor the filter name is allowed to contain spaces.

- C. The filter MyFilter will be invoked after the MyServlet servlet for each request that matches the pattern /my.

- D. The filter MyFilter will be invoked before the MyServlet servlet for each request that matches the pattern /my.

- E. The file is invalid because the <filter> element must contain a <servlet-name> element that defines which servlet the filter should be applied to.

### Filters and Wrappers

(Servlet v2.4 pg. 51)

Which about filters are true? (Choose all that apply.)

- **A.** Filters may be used to create request or response wrappers.
- **B.** Wrappers may be used to create request or response wrappers.
- **C.** Unlike servlets, all filter initialization code should be placed in the constructor since there is no `init()` method.
- **D.** Filters support an initialization mechanism that includes an `init()` method that is guaranteed to be called before the filter is used to handle requests.
- **E.** A filter’s `doFilter()` method must call `doFilter()` on the input `FilterChain` object in order to ensure that all filters have a chance to execute.
- **F.** When calling `doFilter()` on the input `FilterChain`, a filter’s `doFilter()` method must pass in the same `HttpServletRequest` and `HttpServletResponse` objects that were passed into it.
- **G.** A filter’s `doFilter()` method may block further request processing.

---

Which are true about the servlet Wrapper classes? (Choose all that apply.)

- **A.** They provide the only mechanism for wrapping `HttpServletResponse` objects.
- **B.** They can be used to decorate classes that implement `Filter`.
- **C.** They can be used even when the application does NOT support HTTP.
- **D.** The API provides wrappers for `HttpServletRequest`, `HttpServletResponse`, and `FilterChain` objects.
- **E.** They implement the Intercepting Filter pattern.
- **F.** When you subclass a wrapper class, you must override at least one of the wrapper class’s methods.

Someone has done this already. If you're just starting to develop web applications in Java, you're lucky. You get to exploit the collective wisdom of the tens of thousands of developers who've been down that road and got the t-shirt. Using both J2EE-specific and other design patterns, you can simplify your code and your life. And the most significant design pattern for web apps, MVC, even has a wildly popular framework, Struts, that'll help you craft a flexible, maintainable servlet Front Controller. You owe it to yourself to take advantage of everyone else's work so that you can spend more time on the more important things in life (skiing, golf, salsa dancing, soccer, poker, playing the accordion...).
Chapter 14. Enterprise Design Patterns

official Sun exam objectives

OBJECTIVES

J2EE Patterns

11.1 Given a scenario description with a list of issues, select the one of the following patterns that would solve those issues: Intercepting Filter, Model-View-Controller, Front Controller, Service Locator, Business Delegate, and Transfer Object.

11.2 Match design patterns with statements describing potential benefits that accrue from the use of the pattern, for any of the following patterns: Intercepting Filter, Model-View-Controller, Front Controller, Service Locator, Business Delegate, and Transfer Object.

Coverage Notes:
The objectives in this section are covered completely in this chapter. No, make that MORE than completely. The exam questions on patterns are the least tricky of all the possible questions you’ll see on the exam, so you can almost relax in this section.

If you’re already familiar with the fundamental enterprise design patterns, you can probably answer the exam questions on patterns.

And although Struts is not on the exam, this chapter also includes an introduction to Struts, currently the most commonly-used framework for an MVC web application.
Web site hardware can get complicated

In the Real World, web apps can get complicated. A popular web site can get hundreds of thousands of hits per day. To handle this kind of volume, most big web sites create complex hardware architectures in which the software and data is distributed across many machines.

A common architecture you’re probably quite familiar with is configuring the hardware in layers or “tiers” of functionality. Adding more computers to a tier is known as horizontal scaling, and is considered one of the best ways to increase throughput.

Most of the software for a big web application lives in either the “Web Tier” or the “Business Tier”.

The “Web Tier” or “Presentation Tier”. This is where the servlets and JSP’s live. As a web site gets more hits, more servers can be added to handle the load.

The “Business Tier”. This is where business logic lives. More servers can be added when a web site needs to handle more volume.
Web application software can get complicated

As we’ve seen, it’s very common for a web application to be made up of many different kinds of software components. The web tier frequently contains HTML pages, JSPs, servlets, controllers, model components, images, and so on. The business tier can contain EJBs, legacy applications, lookup registries, and in most cases database drivers, and databases.

How am I going to keep all this stuff organized? What if the requirements change? How can I get this to run fast?

This is Internet time, baby. That code is weeks old... Time for some new features!
Lucky for us, we have J2EE patterns

The good news is that a lot of people have been using J2EE containers to solve the very same problems you’re likely to encounter. They found reoccurring themes in the nature of the problems they were dealing with, and they came up with reusable solutions to these problems. These design patterns have been used, tested, and refined by other developers, so you don’t have to reinvent the wheel.

Common pressures

The most important job for a web app is to provide the end user with a reliable, useful, and correct experience. In other words, the program must satisfy the functional requirements such as “select a beer style” or “add malt to my shopping cart”. Once you’ve made sure that the system supports the use cases, you’ll most likely be faced with another set of requirements—requirements for what happens behind the scenes, i.e. the non-functional requirements.

What are the “ilities”?

What are some of the important non-functional requirements of a system you’ve worked on (or could imagine working on)? One clue is that most of the requirements words end with “ility” (for example, “maintainability”).

patterns and struts
Chapter 14. Enterprise Design Patterns

Performance (and the "ilities")

Here are three of the most important non-functional requirements you’re likely to face:

1. **Performance**
   If your website is too slow, you’ll (obviously) lose users. In this chapter, we’ll look at how patterns can help an individual user experience faster **response time**, and how patterns can help your system support a greater number of simultaneous users **(throughput)**. (More on this when we discuss the Transfer Object.)

2. **Modularity**
   In order for different pieces of your application to run on different boxes at the same time, your software is going to have to be modular... and modular in just the right ways.

3. **Flexibility, Maintainability, and Extensibility**
   **Flexibility:** You need to change your system without going through some big development cycle. You might need to swap in the "limited time, special offer" components for a big sale. You might find a bug in a new component and need to swap in the older component temporarily. You need your system to be flexible.

   **Maintainability:** You might need to change database vendors, and update your system quickly. You might get obscure bugs and need to track them down ASAP. The admins might decide to restructure the company’s naming service, and you’ll have to adjust—right now! You need your system to be maintainable.

   **Extensibility:** The guys over in marketing might need a new feature to land that big client. Your users might demand that you support a brand new feature that their browsers have. Your system had better be extensible!
Aligning our vernaculars...

All of the J2EE patterns rely heavily on common software design principles you’re probably very familiar with. In the next few pages, we’ll be exploring several terms for these design principles. Different people and books might have different perspectives on the same terms, so we’re giving you our definitions now, so that you’ll know what we mean.

Code to interfaces

As you recall, an interface is a kind of a contract between two objects. When a class implements an interface, it’s saying in effect: “My objects can speak your language.” Another huge benefit of interfaces is polymorphism. Many classes can implement the same interface. The calling object doesn’t care who it’s talking to as long as the contract is upheld. For example, a web container can use any component that implements the Servlet interface.

Separation of Concerns & Cohesion

We all know that when we specialize the capabilities of our software components, they get easier to create, maintain, and reuse. A natural fallout of separating concerns is that cohesion tends to increase. Cohesion means the degree to which a class is designed for one, cohesive, task or purpose.

Hide Complexity

Hiding complexity often goes hand in hand with separating concerns. For instance if your system needs to communicate with a lookup service, it’s best to hide the complexity of that operation in a single component, and allow all the other components that need access to the lookup service to use that specialized component. This approach simplifies all of the system components that are involved.
More design principles...

Loose Coupling
By their very nature, OO systems involve objects talking to each other. By coding to interfaces, you can reduce the number of things that one class needs to know about another class to communicate with it. The less two classes know about each other, the more loosely coupled they are to each other. A very common approach when class A wants to use methods in class B is to create an interface between the two. Once class B implements this interface, class A can use class B via the interface. This is useful, because later on you can use an updated class B or even an entirely different class, as long as it upholds the contract of the interface.

Remote Proxy
Today, when a web site grows, the answer is to lash together more servers, as opposed to upgrading a single, huge, monolithic server. The outcome is that Java objects on different machines, in their own separate heaps, have to communicate with each other.

Leveraging the power of interfaces, a remote proxy is an object local to the "client" object that pretends to be a remote object. (The proxy is remote in that it is remote from the object it is emulating.) The client object communicates with the proxy, and the proxy handles all the networking complexities of communicating with the actual "service" object. As far as the client object is concerned, it's talking to a local object.

Increase Declarative Control
Declarative control over applications is a powerful feature of J2EE Containers. Most commonly, this declarative control is implemented using the application's deployment descriptor (or DD). Modifying the DD gives us the power to change system behaviors without changing code. The DD is an XML file that can be maintained and updated by non-programmers. The more that we write our web applications to leverage the power of the DD, the more abstract and generic our code becomes.
Patterns to support remote model components

We’ve talked at a very theoretical level about how J2EE patterns can help simplify complex web applications. We’ve also talked about the software design principles that underlie J2EE patterns. With that foundation in place, let’s get our feet wet by talking about a few of the simpler J2EE patterns. All three of the patterns we’re about to discuss share the goal of making remote model components manageable.

A Fable: The Beer App Grows

Once upon a time there was a small dot com that had a website that offered home brewing recipes, advice, ingredients and supplies for beer aficionados. Being a small company (with big plans), they had only one production server to support the site, but they had created two separate software development teams to grow the application. The first team, known as the “Web Designers” focused their attentions on the view components of the system. The second team, known as the “Business Team” focused their attention on the controller components (Rachel’s focus), and the model components (Kim’s area).

It’s the user experience dude... We’re all about the style sheets. Don’t bother us with your business tier issues—we’re creating art.

Performance is really becoming a big issue. We’ve got a small budget for hardware now, but I know we’ll have to be ready to split off more pieces of the app when the time comes.

I’m getting tired...

How the Business Team supports the web designers when the MVC components are running on one JVM

As long as the business guys keep the interfaces to their model components consistent, everyone will be happy. The two key interface points in their design are when the controller first interacts with a model component (steps 1 and 2 below), and then later, when a JSP view interacts with the bean it needs (steps 3 and 4 below).

Getting customer data for a client...

1. Having received a request for customer information, the Controller calls the ManageCustomer service component (a Model). The service component does a JDBC call to the legacy database, then creates a Customer bean (this is NOT an EJB, just a plain old JavaBean), populated with customer data from the database.

2. The Controller adds the Customer bean reference to the request object, as an attribute.

3. The Controller forwards to the View JSP. The JSP gets the reference to the Customer bean from the request object.

4. The View JSP uses EL to get the Customer Bean properties it needs to satisfy the original request.
How will they handle remote objects?

Things are fairly simple when all the web app components (model, view, controller) are on the same server, running in the same JVM. It’s just plain old Java—get a reference, call a method. But Kim and Rachel now have to figure out what to do when their model components are remote to the web app.

JNDI and RMI, a quick overview

Java and J2EE provide mechanisms that handle two of the most common difficulties that arise when objects need to communicate across a network—locating remote objects, and handling all the low level network communications between local and remote objects. (In other words, how to find remote objects, and how to invoke their methods.)

JNDI in a nutshell

JNDI stands for Java Naming and Directory Interface, and it’s an API to access naming and directory services. JNDI gives a network a centralized location to find things. If you’ve got objects that you want other programs on your network to find and access, you register your objects with JNDI. When some other program wants to use your objects, that program uses JNDI to look them up.

JNDI makes relocating components on your network easier. Once you’ve relocated a component, all you need to do is tell JNDI the new location. That way, other client component only need to know how to find JNDI, without knowing where the objects registered with JNDI are actually located.

RMI in a nutshell

RMI stands for Remote Method Invocation, a mechanism that greatly simplifies the process of getting objects to communicate across a network. Turn the page and we’ll do a quick refresh, in case you’re a little rusty. Why think about RMI here? Because it will help make two of the J2EE design patterns easier to understand and appreciate.
RMI overview

RMI makes life easy

You want your objects to communicate across a network. In other words, you want an object in one JVM to cause a method invocation on a remote object (i.e., an object in a different JVM), but you want to pretend that you’re invoking a method on a local object. That’s what RMI gives you—the ability to pretend (almost) that you’re making a regular old local method call.

What we want...

How RMI pulls it off

Let’s say your “business guy” hat is on, and you want to make an object available to remote clients. Using RMI, you’ll create a proxy and you’ll register your object with some sort of registry. Any client who wants to call your methods will do a lookup on the registry and get a copy of the remote proxy. Then the client will make calls on the remote proxy, pretending it’s the real thing. The remote proxy (called a stub), handles all the communications details like sockets, I/O streams, TCP/IP, serializing and deserializing method arguments and return values, handling exceptions, and so forth.

(Oh, by the way, there’s usually a proxy on the server side (often called a “skeleton”), doing similar chores on the server side where the remote object lives.)
patterns and struts

Just a little more RMI review

Without doing an entire RMI tutorial,* we'll look at a few more high level RMI topics to make sure we're all talking the same talk. Specifically, we'll look at the server side and client side of using RMI.

RMI on the Server side in 4 steps

(An overview of the steps to make a remote model service that runs on the server.)

1. Create a remote interface. This is where the signature for methods like `getCostData()` will reside. Both the stub (proxy) and the actual model service (the remote object) will implement this interface.

2. Create the remote implementation, in other words, the actual model object that will reside on the model server. This includes code that registers the model with a well-known registry service such as JNDI or the RMI registry.

3. Generate the stub and (possibly) skeleton. RMI provides a compiler called `rmic` that will create the proxies for you.

4. Start/run the model service (which will register itself with the registry and wait for calls from far-away clients).

The client side, with and without RMI

Let's compare the pseudo-code of a client using RMI to the pseudo-code of a client NOT using RMI.

The client without RMI

```java
public void goClient() {
    try {
        // get a new socket
        // chain it to an ObjectOutputStream
        // send an opcode & op arguments
        // flush OS
        // get the InputStream
        // chain it to an ObjectInputStream
        // read the return value and/or
        // handle exceptions
        // close stuff
    } catch and handle remote exceptions
}
```

The client with RMI

```java
public void goClient() {
    try {
        // lookup the remote object (stub)
        // call the remote object's method
        } catch and handle remote exceptions
    }

    *If you aren't really familiar with RMI, drive to your local bookstore, pick up (but don't buy) a copy of Head First Java, and just read the sections on RMI. Then put the book back on the shelf, face forward, in front of the competing book of your choice. Make sure that the cover is dusted and don't spill coffee on it.
```

you are here ➔ 717
using a remote model

Adding RMI and JNDI to the controller

Let’s focus on what we need to do to keep Rachel’s life as simple as possible. In other words, what impact does adding JNDI and RMI have on the controller?

3 steps to using a remote object

1. Kim, the model guy, registers his model component with the JNDI service.

2. When Rachel’s controller gets a request, the controller code does a JNDI lookup to get the stub proxy for Kim’s remote model service.

3. The controller makes business method calls against the stub, just as though the stub were the actual model object itself. Almost...
patterns and struts

Sure, the method calls are pretty close to what I was doing before when the model was local, but I still have to change the Controller code to put in the whole JNDI lookup. I was hoping for something that would let me use the same Controller regardless of whether the model is local or remote.

Sharpen your pencil

How can this design be improved?

1. What are the problems with this design (list at least two)?
2. How might you change this design to handle those problems?

Problems:

Solution:
**How about a “go-between” object?**

A common solution to the design problems we left you with is to create a new object—a single, “go-between” object for the controller to talk to rather than having the controller deal directly with the remoteness of the remote model.

**Problem 1: Hide the complex JNDI lookup**

If Rachel’s controller lets a “go-between” object handle the JNDI lookup, the controller code can stay simpler, free from having to know where (and how) to look up the model.

**Problem 2: Hide “remote-ness complexity”**

If the “go-between” object can handle talking to the stub, Rachels’ controller can be shielded from all the remote issues including remote exceptions.

This object will hide the JNDI and remote handling complexities.

The “go-between” is a Business Delegate

Let’s take a look at the pseudo-code for a typical Business Delegate, and at how Business Delegates tend to be deployed in the web container.

Notice that there will be LOTS of Business Delegates on the web tier.

A Business Delegate’s pseudo-code

```java
// get the request and do a JNDI lookup
// get back a stub

// call to the business method
// handle & abstract any remote exceptions
// send the return value to the controller
```

Legions of Business Delegates on the web server (one per remote model):

Sharpen your pencil

(Describe where the duplicate code exists and how you could solve that problem.)
Simplify your Business Delegates with the Service Locator

Unless your Business Delegates use a Service Locator, they will have duplicate code for dealing with the lookup service.

To implement a Service Locator, we’ll take all of the logic for doing the JNDI lookup and move it out of the multiple Business Delegates and into a single Service Locator.

Typically in J2EE applications, there will be a number of components that all use the same JNDI service. While a complex application might use several different registries such as JNDI and UDDI (for web service endpoints), an individual component will typically need access to only one registry. In general, a single Service Locator will support a single, specific registry.

By making the Business Delegate an object that handles only the business methods rather than also handling the registry lookup code, you increase the cohesion for the Business Delegates.

A Service Locator’s pseudo-code

// obtain an InitialContext object
// perform remote lookup
// handle remote issues
// optionally, cache references

Cohesion is increased for all of these Business Delegates.

Obtaining the stub is now handled by the Service Locator. All the Delegate has to do is deal with business methods on the stub.

Moving the registry affects only the single Service Locator object.

Optional cache can reduce network calls.
Q: This whole discussion has assumed RMI; what if our company is using CORBA?

A: All of the patterns we’re discussing can be implemented more or less independently of J2EE technologies. Admittedly, they will be easiest to implement in J2EE, but they do apply to other situations.

Q: Is the same thing true for JNDI?

A: Well, there are other Java-related registries besides JNDI—RMI and Jini come to mind. Of those three, JNDI is probably the best choice for most web apps, it’s easy and powerful. (Although the authors would personally love to see Jini take its rightful place in the distributed world.) You might also be dealing with non-Java registries like UDDI. In any case, the patterns will still work, even though the code changes, of course.

Q: It seems like these patterns are forever adding a new layer of objects to the architecture. Why is this approach so common?

A: You’re right that this is a common part of a lot of patterns. Assuming that your design is good, think about the software design benefits inherent in this approach...

Q: OK, well, cohesion comes to mind...

A: Right! Both the Business Delegate and the Service Locator increase the cohesiveness of the objects they support. Another driving force is network transparency. Adding a layer often shields existing objects from being network aware. Then of course, closely related to cohesion is separation of concerns.

Q: Separation of concerns buys me...?

A: Let’s take the Service Locator as an example. In the event that your registry gets a new network address and/or registry interface, it’s far easier to modify a single Service Locator than change a whole flotilla of Business Delegates. In general, separation of concerns buys us a lot of flexibility and maintainability.

Q: In your examples so far, you’ve taken POJOs that were local, and made them remote. Isn’t it more likely that I’ll be faced with integrating existing EJBS into my web app?

A: By POJOs, we assume you mean ‘Plain Old Java Objects’, of course. And yes, it is likely that you’ll be integrating EJBS into your app. And in fact that’s yet another reason to use these two patterns... your controller (and view) should never have to care whether the model is a local Javabeen, a remote POJO, or an enterprise JavaBean (EJB). Without using ServiceLocator and Business Delegate, that difference means a lot—enterprise beans and plain old remote objects don’t use the same lookup code!

Using these patterns, you can encapsulate the issues related to how and where the model is discovered and used, and keep the controller happy and clueless, so that you won’t have to change your controller code when the business guys change things and move things around on the business tier. You’ll update only the Service Locator and (possibly) the Business Delegate.
Protecting the web designer’s JSPs from remote model complexity

By using the Business Delegate and Service Locator patterns, we’ve got Rachel’s controllers protected from the complexities of remote model components. Now let’s see if we can do the same for the web designer’s JSPs.

Quick review of the old non-remote way— the JSP uses EL to get info from the local model.

This diagram should look familiar from earlier in the chapter. The JSP gets the bean reference from the request object (step 3), then calls getters on the bean (step 4).

1. Having received a request for customer information, the Controller calls the ManageCustomer model component. The model component does a remote call to the legacy database, then creates a Customer bean, populated with customer data from the database.

2. The Controller adds the Customer reference to the request, as an attribute.

3. The controller forwards to the View JSP. The JSP gets a reference to the Customer bean from the request object.

4. The View JSP uses EL to get the Customer Bean properties it needs to satisfy the original request.

These can be simple EL expressions like:

$\{customer.name\}
**Compare the local model diagram to this remote model diagram**

The shaded area in this diagram should look a lot like the previous diagram, especially if you remember that the Business Delegate is pretending to be the Manage Customer model.

---

**A 6-step review:**

1. Register your services with JNDI.
2. Use Business Delegate and Service Locator to get the Manage Customer stub from JNDI.
3. Use the Business Delegate and the stub to get the “Customer Bean”, which in this case is another stub. Return this stub’s reference to the controller.
4. Add the Customer stub reference to the request.
5. The controller forwards to the View JSP. The JSP gets a reference to the Customer bean (stub) from the request object.
6. The View JSP uses EL to get the Customer Bean properties it needs to satisfy the original request.

**BIG NOTE:** Every time the JSP invokes a getter, the Customer stub makes a network call.
There’s good news and bad news...

The previous architecture succeeds in hiding complexity from both the controllers and the JSPs. And it makes good use of the Business Delegate and Service Locator patterns.

The bad news:

When it’s time for the JSP to get data, there are two problems, both related to the fact that the bean the JSP is dealing with is actually a stub to a remote object.

1. *All those fine-grained network calls are likely to be a big performance hit.* Think about it. Each EL expression triggers a remote method invocation. Not only is this a bandwidth/latency issue, but all those calls cause the server some problems too. Each call might lead to a separate transaction and database load (and possibly store!) on the server.

2. The JSP is *not a good place to be handling exceptions* that might occur if the remote server crashes.

Why not have the JSP talk to a plain old bean instead of a stub?

**Q:** If you want the JSP to talk to a JavaBean, where will this bean come from?

**A:** Well, it used to come from the local model/service object, so why not have it come from the remote model/service object?

**Q:** How do you get a bean across the network?

**A:** Hey, as long as it’s serializable, RMI has no problem sending an object across the network.

**Q:** So what would this buy us again?

**A:** First of all, we’d have one big network call instead of a lot of little ones. Second, since the JSP would be talking to a local object, there’d be no remote exceptions to worry about!

**Q:** Wait a minute... I see a little problem here. Or maybe a big problem—if you’re using a bean on the client side, doesn’t that bean’s data become stale the moment it’s sent?

**A:** Yes, you’re right, and this is a trade-off: performance vs. how current the data is. You have to decide which makes sense based on your requirements. If the data used by your view component must absolutely, positively, represent the current state of the database at all times, then you need a remote reference. For example, if you make three calls, say, getName(), getAddress(), and getPhone() on customer, you’ll probably decide that this information doesn’t change rapidly enough to make it worth going back to the database (via the remote object) just in case the customer’s phone number changed IN BETWEEN the call to getName() and getAddress().

On the other hand, you might decide that in a highly dynamic environment, where a customer is making transactions 24/7, you DO need to show the most up-to-date info. Sending a JavaBean back for the client means the View would have a snapshot of the database at the moment the bean was populated, but since the bean has no connection to the database, the data begins to go stale immediately.
Time for a Transfer Object?

If it’s likely that a business service might be asked to send or receive all or most of its data in a big, coarse-grained message, it’s common for that service to provide that feature in its API. Commonly, the business service creates a serializable Java object that contains lots of instance variables. Sun calls this object a Transfer Object. Outside of Sun there is a pattern called Data Transfer Object. Guess what? They’re the same thing. (Yeah, we feel the same way about that.)

The client’s perspective, inside the Business Delegate:

```java
try {
    Customer c = custStub.getCustData(custID);
} catch (RemoteException re) {
    throw new CustomerException();
}
```

That’s it. Under the covers, the Transfer Object is serialized, shipped, and deserialized on to the client’s local JVM heap. At that point, it is just like any other local bean.

The data in a Transfer Object grows stale!

Once it’s shipped across the network, the Transfer Object is completely out of touch with its source, and begins to fall out of sync with the state of the data in the underlying database. You’ll have to decide for each use case whether data integrity/synchronization is worth the performance hits.
service locator vs. business delegate

Service Locator and Business Delegate both simplify model components

Service Locator is the superior pattern. First of all, unlike the Business Delegate, one Service Locator instance can support an entire application tier.

That's true, but Service Locator needs to talk to only one remote entity. Business Delegate must handle many entity objects.

Service Locator is more efficient with network calls. It can cache references to stubs or service stubs once it has located them, reducing network traffic for subsequent calls.

With much respect, you are forgetting that Service Locator has a much easier task. The Business Delegate must carry the heavy burden of communicating with a dynamic object, whose data might change at any moment.

Heavy burden? Your simple business data does not impress me.

A Business Delegate gives web application programmers much more benefit than your Service Locator.

Ah, maybe programmers do benefit, but your simple pattern seems to forget that it often exists in a network environment. It will make many calls to business services with no restraint, no consideration for the overhead of remote calls.

Ah ha! The Business Delegate is not ashamed to form an alliance with the Transfer Object! Working as a team, they help the programmer AND minimize remote calls.

Yes, yes, your weak pattern needs assistance, we all know that. But when you partner with a Transfer Object other demons can haunt you... you haven't forgotten your little problems with data staleness and concurrency, have you?

No, I haven't forgotten. But when these issues come up they can be solved. You cannot expect to achieve great things without a little extra effort... nothing in J2EE is ever black and white.
Business tier patterns: quick review

To wrap up our discussion of business tier patterns, here’s a diagram that shows a Business Delegate, a Service Locator, and a Transfer Object in action. At the end of the chapter you’ll find a couple of summary pages for these patterns and the presentation tier patterns we’ll discuss next.

A 6-step review:
1. Register your services with JNDI.
2. Use Business Delegate and Service Locator to get the Manage Customer stub from JNDI.
3. Use the Business Delegate and the stub to get the “Customer Bean”, which in this case is a Transfer Object. Return this Transfer Object’s reference to the controller.
4. Add the bean’s reference to the request.
5. The controller forwards to the View JSP. The JSP gets the reference to the Customer Transfer Object bean from the request object.
6. The View JSP uses EL to get the Customer Transfer Object Bean’s properties it needs to satisfy the original request.
MVC app

Our very first pattern revisited... MVC

As luck would have it the very same pattern we’ve been using in the book is on the exam. The last two patterns we’re covering are presentation tier patterns, as was the Intercepting Filter.
First we’ll pick up where we left off talking about MVC. That discussion will lead us into Struts and finally Front Controller.

Where we left off...

Let’s do a quick review of where we left off in chapter 2.

MODEL
Holds the real business logic and the state. In other words, it knows the rules for getting and updating state.
A Shopping Cart’s contents (and the rules for what to do with it) would be part of the Model in MVC.
It’s the only part of the application that talks to the database.

CONTROLLER
Takes user input from the request and figures out what it means to the model.
Tells the model to update itself, makes the model state available for the view (the JSP) and forwards to the JSP.

VIEW
Responsible for the presentation. It gets the state of the model from the Controller (although not directly: the Controller puts the model data in a place where the View can find it).

Off Track: GUI MVC vs Web MVC

MVC existed before the World Wide Web came along. In its first incarnation, MVC was a design to simplify complex GUI applications. First created in Smalltalk, one of MVC’s chief attributes was that the View would be notified automatically of changes to the Model.
More recently, MVC has been used on the web, even though the View is in the browser and cannot be automatically updated when the Model changes in the web tier. Our focus is entirely on the web version of MVC.
Finally, we’re always talking about MVC, model 2, never the older Model 1 or 1.5 MVCs.
MVC in a real web app

Way back in chapter two, we left you with a “Flex your mind” exercise about potential problems with our Dating App MVC architecture. Let’s review where we left off and get around to answering the question that’s certainly been haunting you for all these chapters: what could possibly be better than MVC?

For each browser use case, there will be a corresponding set of Model, View, and Controller components, which might be mixed and matched and recombined in many different ways from use case to use case.

The problem we had in the dating app was that we had many specialized controllers, which sounded good from an OO perspective, but left us with duplicate code across all the different controllers in our app, and didn’t give us a nice happy feeling about maintainability and flexibility.

A single MVC app will have many models, views, and controllers.
the MVC controller

Looking at the MVC controller

Let’s see if we agree with what’s been said about controllers. First, a reminder about the controller servlet’s job:

Pseudo-code for a generic MVC controller

```java
public class ControllerServlet extends HttpServlet {
    public void doPost(request, response) {
        String c = req.getParameter("startDate");
        // do a data conversation on the date parameter
        // validate that date is in range
        // if any errors happen in validation,
        // forward to hardcoded “retry” JSP

        // invoke the hardcoded model component(s)
        // add model results to the request obj.
        // (maybe a reference to a bean)

        // dispatch to the view JSP
        // (of course it’s hard coded)
    }
}
```

Deal with the request parameters

Deal with the model

Deal with the view

Sharpen your pencil

What principles does this component violate?

List three or more software design principles this pseudo-code violates.
Improving the MVC controllers

Besides a lack of cohesiveness, the controller is also tightly coupled to the model and the view components. And there’s yet another Duplicate Code Alert here. How can we fix things?

### The controller’s three main tasks

<table>
<thead>
<tr>
<th>The controller’s three main tasks</th>
<th>A better way to handle it?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get and deal with the request parameters</td>
<td>Give this task to a separate form validation component that can get the form parameters, convert them, validate them, handle validation errors, and create an object to hold the parameter values.</td>
</tr>
<tr>
<td>Invoke the model</td>
<td>Hmm... we don’t like hard-coding the model into the controller, so maybe we could do it declaratively, listing a bunch of models in our own custom deployment descriptor that the controller could read and, based on the request, figure out which model(s) to use.</td>
</tr>
<tr>
<td>Dispatch to the View</td>
<td>Why not make this declarative as well? That way, based on the request URL, the controller can tell (from our custom deployment descriptor) which view to dispatch to.</td>
</tr>
</tbody>
</table>

### New and (shorter) controller pseudo-code

```java
public class ControllerServlet extends HttpServlet {

    public void doPost(request, response) { // call a validation component declaratively
        // (have it handle validation errors too!)
        // declaratively invoke a request processing
        // component, to call a Model component
        // dispatch to the view JSP declaratively
    }
}
```

This looks great to me! I’ll feel a lot less schizophrenic if I’m designed this way.

Controller
Designing our fantasy controller

Let’s do another one of our now-infamous architectural diagrams to see what this controller and its support components might look like.

1. Having received a request, the Controller locates the correct Form Validation Component in the Declarations XML file. The Controller invokes the Form validator, sending it the request. If the validator finds any errors, it tells the controller which view to return.

2. Using the Declarations XML file, the Controller locates and invokes the Request Action Component component, which invokes the model.

3. Using the Declarations XML file, the Controller locates and invokes the View.
Yes! It’s Struts in a nutshell

Obviously this is an overview, and we’ve left out pretty much all of the details, but this is the basic idea behind the Struts framework. Let’s look at a few more details, starting with the fact that we’ve changed all the names...

Key Struts Components

**Action Servlet** - You’ll need only one of these per application. Best of all, you don’t even have to write it. Struts provides it.

**Form Beans** - You’ll write one of these for each HTML form your app needs to process. They are Java beans, and once the Struts ActionServlet has called the setters on the form bean (to populate the bean with form parameters), it will call the bean’s validate() method. This is a great place to put data conversion and error handling logic.

**Action Objects** - Generally, an action maps to a single activity in a use-case. It has a call-back-like method called execute(), which is a great place to get the validated form params, and call model components. Think of the Action object as kind of a “servlet lite”.

**struts-config.xml** - This is the Struts-specific deployment descriptor. In it you’ll map request URLs to Actions, Actions to Form beans, and Actions to views.

...
The Struts Framework

Is Struts a container?

Officially, Struts is considered a framework. Frameworks are collections of interfaces and classes that are designed to work together to handle a particular type of problem. In the case of Struts, the problem space is web applications. The goal of a framework is to “aid programmers in the development and maintenance of complex applications”. So, Struts isn’t a container, but in some ways it acts like one.

Top five ways Struts is like a servlets container

1 Declarative: They both use an XML file to configure the application declaratively.

2 Lifecycle: They both provide lifecycles for predetermined types of objects.

3 Callbacks: They both perform automatic callbacks of key lifecycle methods.

4 APIs: They both provide APIs for key types of objects that are supported.

5 Application Control: They both provide a controlled environment in which your application runs. They are your application’s window to the outside world.

Relax! There is nothing about Struts on the exam!

You ARE expected to know the purpose and function of a Front Controller (and Struts is just a tricked-out Front Controller), but you will not have any questions about the Struts framework. So, you can relax and focus along without having to memorize every tricky detail.

I feel an analogy coming on... you’ve said Struts has “call-back” methods and a deployment descriptor. So is Struts like a mini-container?

In Struts, I’ve been promoted to “Action Servlet”. Sometimes I’m also referred to as a Front Controller. (That’s on the exam, by the way.)
How does Front Controller fit in?

Oh yeah. Front Controller is another J2EE pattern, and it just happens to be on the exam. Actually, Struts is a really fancy example of using a Front Controller pattern. The basic idea of the Front Controller pattern is that a single component, usually a servlet but possibly a JSP, acts as the single control point for the presentation tier of a web application. With the Front Controller pattern, all of the app’s requests go through a single controller, which handles dispatching the request to the appropriate places.

In the real world, it’s rare to implement a Front Controller all by itself. Even a really simple implementation usually includes another J2EE pattern called an Application Controller. Struts includes a class called the RequestProcessor, which is ultimately responsible for the handling of HTTP requests.

Although the exam might contain questions about the Front Controller pattern, you’ll be fine if you remember the benefits of Struts, and the fact that Struts is simply a Front Controller with all the bells and whistles.

Eight features that Struts adds to a Front Controller

1 Declarative Control: Struts allows you to create declarative maps between request URLs, validation objects, model-invoking objects, and views.

2 Automated Request Dispatching: The Action.execute() method returns a symbolic ActionForward which tells the ActionServlet which view to dispatch to. This provides another layer of abstraction (and loose coupling) between the controller and view components.

3 DataSources: Struts can provide DataSource management.

4 Custom Tags: Struts provides dozens of custom tags.

5 Internationalization Support: Error classes and custom tags have internationalization support.

6 Declarative Validation: Struts provides a validation framework that removes the need to code the validate method in your form beans. The rules for validating a form are configured in an XML file and can be changed without affecting your form bean code.

7 Global exception handling: Struts provides a declarative error handling mechanism similar to <error-page> in the DD. However, with Struts the exceptions can be specific to the application code in your Action object.

8 Plug-ins: Struts provides a Plugin interface with two methods: init() and destroy(). You can create your own plug-ins to enhance your Struts application, and they will be managed for you. For example, the Validator framework is initialized using a plug-in.
the beer app in Struts

Refactoring the Beer app for Struts

Enough theory. Let's write a Struts app. First off, let's review our MVC Beer app from chapter 3. The only code that's going to change when we refactor to Struts is related to the MVC controller. (The model and view are not affected.)

1. Having received a request, the Controller performs validation of the user form data.
2. The Controller invokes the Model component.
3. The Controller forwards to the View.

MVC controller code
(from chapter 3)

```java
package com.example.web;
import com.example.model.*;
import javax.servlet.*;
import javax.servlet.http.*;
import java.io.*;
import java.util.*;

public class BeerSelect extends HttpServlet {
    public void doPost(HttpServletRequest request,
            HttpServletResponse response)
            throws IOException, ServletException {
        String color = request.getParameter("color");
        BeerExpert be = new BeerExpert();
        ArrayList result = be.getBrands(color);
        request.setAttribute("styles", result);
        RequestDispatcher disp = request.getRequestDispatcher("result.jsp");
        disp.forward(request, response);
    }
}
```

Not a lot of form validation going on here. :)
Forward to the hardcoded View.
The Struts Beer app architecture

Here’s the Beer app architecture, all done up in Struts...

1. Having received a request, the 
ActionServlet locates the correct form 
bean using the struts-config.xml file. The 
ActionServlet invokes the form bean’s validation 
logic. If the form bean finds any errors, it 
populates an ActionErrors object.

2. Using the struts-config.xml file, the 
ActionServlet locates and invokes the Action 
object, which invokes the model and returns an 
ActionForward object to the ActionServlet.

3. Having previously extracted the necessary 
mappings from struts-config.xml, the 
ActionServlet uses the ActionForward object to 
dispatch to the correct view component.

Well, OK, the view *will* change 
in a Struts web app. For one thing, 
Struts provides a tag library that 
provides a tag, `<html:errors/>`, that 
displays the form bean validation 
errors. Also, the HTML tag library 
provides tags that repopulate the 
form on an error.
A form bean exposed

Remember, the form bean’s job is to validate the user’s form params. A nice benefit of Struts is that a validation step is built right into the architecture.

```java
package com.example.web;

// Struts imports
import org.apache.struts.action.ActionMapping;
import org.apache.struts.action.ActionForm;
import org.apache.struts.action.ActionErrors;
import javax.servlet.http.HttpServletRequest;

public class BeerSelectForm extends ActionForm {
    private String color;
    public void setColor(String color) {
        this.color = color;
    }
    public String getColor() {
        return color;
    }
    private static final String VALID_COLORS = "amber,dark,light,brown";
    public ActionErrors validate(ActionMapping mapping,
                                  HttpServletRequest request) {
        ActionErrors errors = new ActionErrors();
        if (VALID_COLORS.indexOf(color) == -1) {
            errors.add("color", new ActionError("error.colorField.notValid"));
        }
        return errors;
    }
}
```
How an Action object ticks

The Action object is mainly a dispatcher. It is invoked by the ActionServlet, which calls the Action object's execute() method.

```java
package com.example.web;

// Model imports
import com.example.model.*;
import java.util.*;

// Struts imports
import org.apache.struts.action.Action;
import org.apache.struts.action.ActionMapping;
import org.apache.struts.action.ActionForm;
import org.apache.struts.action.ActionForward;

// Servlet imports
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

public class BeerSelectAction extends Action {

    public ActionForward execute(ActionMapping mapping, ActionForm form,
                                 HttpServletRequest request,
                                 HttpServletResponse response) {

        // Cast the form to the application-specific form
        BeerSelectForm myForm = (BeerSelectForm) form;

        // Process the business logic
        BeerExpert be = new BeerExpert();
        ArrayList result = be.getBrands(myForm.getColor());

        // Get the request scope
        // (and store the data in the request-scope)
        request.setAttribute("styles", result);

        return mapping.findForward("show_results");
    }
}
```
The Struts

code

struts-config.xml: tying it all together

The struts-config.xml file is analogous to the DD. You can actually call it whatever you want, although struts-config.xml is its conventional name. Similar to the DD, this file is where you’ll declare and map Struts components in your web app. This mechanism helps your application become more loosely coupled.

```xml
<?xml version="1.0" encoding="ISO-8859-1" ?>
<struts-config PUBLIC
"http://jakarta.apache.org/struts/dtds/struts-config_1_0.dtd">
<struts-config>
<form-beans>
  <form-bean name="selectBeerForm" types="com.example.web.BeerSelectForm" />
</form-beans>
'action-mappings'>
  <action path="/SelectBeer" type="com.example.web.BeerSelectAction" name="selectBeerForm" scope="request" validate="true" input="/form.jsp">
    <forward name="show_results" path="/result.jsp" />
  </action>
</action-mappings>

<message-resources parameter="ApplicationResources" null="false" />
</struts-config>
```

The `<form-bean>` element declares the symbolic name and class of a form bean object.

An `<action>` element maps the URL path to the controller class; notice that the .do extension for the path is NOT included in the Struts configuration.

The `<action>` also associates a form bean with the action. This is specified by the symbolic form bean name. Struts will create this bean and store it in the specified scope. If validation occurs and errors are returned from the validate method, then the input attribute declares the View responsible for displaying the error message; this is usually the form that submitted this action.

The `<forward>` element creates a mapping between the symbolic view name, used by the Action object, and the physical path to the view component.

Chapter 14. Enterprise Design Patterns

Head First Servlets and JSP By Bert Bates, Kathy Sierra, Bryan Basham ISBN: 0596005407 Publisher:Prepared for Augusto Jaramillo Forcada, Safari ID: augustojf.cv@gmail.com

Specifying Struts in the web.xml DD

As far as the Container is concerned, the ActionServlet is just another servlet. So, you have to declare it and make sure all of the web app’s requests are mapped to it.

```xml
<web-app xmlns="http://java.sun.com/xml/ns/j2ee"
xmns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd"
version="2.4">
<!-- Define the controller servlet -->
<servlet>
<servlet-name>FrontController</servlet-name>
<servlet-class>org.apache.struts.action.ActionServlet</servlet-class>

<!-- Name the struts configuration file -->
<param-name>config</param-name>
<param-value>/WEB-INF/struts-config.xml</param-value>
</init-param>

<!-- Guarantee that this servlet is loaded on startup. -->
<load-on-startup>1</load-on-startup>
</servlet>

<!-- The Struts controller mapping -->
<servlet-mapping>
<servlet-name>FrontController</servlet-name>
<url-pattern>*.do</url-pattern>
</servlet-mapping>
</web-app>
```
installing Struts

Install Struts, and Just Run It!

Installing Struts is simple.
The links and versions mentioned on this page were current at
the time of this writing. Which is no help at all for you, but means
simply: we have no idea what things will be like by the time you read this,
but we gave it our best shot anyway.

Six easy steps to installing Struts

1. Crank up your browser and navigate to:
   http://jakarta.apache.org/site/binindex.cgi

2. Scroll down to the Struts section and select the link to:
   1.1 zip

3. Download the zip file to a temporary directory.

4. Unzip the file which unpacks to:
   jakarta-struts-1.1/
   README
   lib/
   struts.jar
   commons-beanutils.jar
   commons-digester.jar
   webapps/
   ......

5. Copy the following files to your webapp’s
WEB-INF/lib/ directory:
   struts.jar
   commons-beanutils.jar
   commons-digester.jar

6. FYI: make sure that there is a copy of struts.jar in
your classpath when you compile your form beans and
action objects. (Remember, the ActionServlet front
controller is created for you automatically.)

744 chapter 14
Creating the deployment environment

This is the directory structure you will create to run the Struts version of the Beer app.

You'll create one of these if you want to internationalize the text displayed to your user. Rather than hard-code error text or other Strings for display, you can use a resources properties file to provide key/value mappings, and in your JSP, you can invoke a special tag for the key, and the mapped text will be displayed.

These three JAR files are the core Struts library and two common libraries used by Struts.
**Patterns review for the SCWCD**

We’ve covered a lot of patterns in the last two chapters. The next few pages pull together a lot of the details you’ll want to study for the SCWCD exam.

**Business Delegate**

Use the Business Delegate pattern to shield your web tier controllers from the fact that some of your app’s model components are remote.

---

**Business Delegate features**

- Acts as a proxy, implementing the remote service’s interface.
- Initiates communications with a remote service.
- Handles communication details and exceptions.
- Receives requests from a controller component.
- Translates the request and forwards it to the business service (via the stub).
- Translates the response and returns it to the controller component.
- By handling the details of remote component lookup and communications, allows controllers to be more cohesive.

---

**Business Delegate principles**

- The Business delegate is based on:
  - hiding complexity
  - coding to interfaces
  - loose coupling
  - separation of concerns
  - Minimizes the impact on the web tier when changes occur on the business tier.
  - Reduces coupling between tiers.
  - Adds a layer to the app, which increases complexity.
  - Method calls to the Business Delegate should be coarse-grained to reduce network traffic.
Service Locator

Use the Service Locator pattern to perform registry lookups so you can simplify all of the other components (such as Business Delegates) that have to do JNDI (or other registry types) lookups.

Service Locator features
- Obtains Initial/Context objects.
- Performs registry lookups.
- Handles communication details and exceptions.
- Can improve performance by caching previously obtained references.
- Works with a variety of registries such as JNDI, RMI, UDDI, and COS naming.

Service Locator principles
- The Service Locator is based on:
  - hiding complexity
  - separation of concerns
  - Minimizes the impact on the web tier when remote components change locations or containers.
  - Reduces coupling between tiers.
Transfer Object

Use the Transfer Object pattern to minimize network traffic by providing a local representation of a fine-grained remote component (usually an entity).

Transfer Object functions

- Provides a local representation of a remote entity (i.e., an object that maintains some data state).
- Minimizes network traffic.
- Can follow Java bean conventions so that it can be easily accessed by other objects.
- Implemented as a serializable object so that it can move across the network.
- Typically easily accessible by view components.

Transfer Object principles

- The Transfer Object is based on:
  - reducing network traffic.
  - Minimizes the performance impact on the web tier when remote components' data is accessed with fine-grained calls.
  - Reduces coupling between tiers.
  - A drawback is that components accessing the Transfer Object can receive out-of-date data, because the Transfer Object's data is really representing state that's stored somewhere else.
  - Making updatable Transfer Objects concurrency-safe is typically complex.
Intercepting Filter

Use the Intercepting Filter pattern to modify requests being sent to servlets, or to modify responses being sent to users.

- Can intercept and/or modify requests before they reach the servlet.
- Can intercept and/or modify responses before they are returned to the client.
- Filters are deployed declaratively using the DD.
- Filters are modular so that they can be executed in chains.
- Filters have lifecycles managed by the Container.
- Filters must implement Container callback methods.

The Intercepting Filter is based on:
- cohesion
- loose coupling
- increasing declarative control

Declarative control allows Filters to be easily implemented on either a temporary or permanent basis.

Declarative control allows the sequence of invocation to be easily updated.
**MVC pattern**

**Model, View, Controller (MVC)**

Use the MVC pattern to create a logical structure that separates the code into three basic types of components (Model, View, Controller) in your application. This increases the cohesiveness of each component and allows for greater reusability, especially with model components.

**Model, View, Controller features**

- Views can change independently from controllers and models.
- Model components hide internal details (data structures), from the view and controller components.
- If the model adheres to a strict contract (interface), then these components can be reused in other application areas such as GUIs or J2ME.
- Separation of model code from controller code allows for easier migration to using remote business components.

**Model, View, Controller principles**

- Model, View, Controller is based on:
  - separation of concerns
  - loose couplings
  - increases cohesion in individual components.
  - Increases the overall complexity of the application. (This is true because even though individual components become more cohesive, MVC adds many new components to the application.)
- Minimizes the impact of changes in other tiers of the application.
Front Controller

Use the Front Controller pattern to gather common, often redundant, request processing code into a single component. This allows the application controller to be more cohesive and less complex.

Front Controller features
- Centralizes a web app’s initial request handling tasks in a single component.
- Using the Front Controller with other patterns can provide loose coupling by making presentation tier dispatching declarative.
- A drawback of Front Controller (on its own, without Struts) is that it’s very barebones compared to Struts. To create a reasonable application from scratch using the Front Controller pattern, you would end up rewriting many of the features already found in Struts.

Front Controller principles
- The Front Controller is based on:
  - hiding complexity
  - separation of concerns
  - loose coupling
  - Increases cohesion in application controller components.
  - Decreases the overall complexity of the application.
  - Increases the maintainability of the infrastructure code.
mock exam

Mock Exam Chapter 14

1. Given this list of attributes:
   - related to Intercepting Filter
   - supports role separation between developers
   - adds reusability
   Which design pattern is being described?
   - A. Transfer Object
   - B. Service Locator
   - C. Front Controller
   - D. Business Delegate

2. The design of your web application calls for certain security measures to be taken for every request received. Some of these security checks will be applied, regardless of the type of request.
   Which design pattern can be used to achieve this design requirement?
   - A. Transfer Object
   - B. Service Locator
   - C. Composite Entity
   - D. Business Delegate
   - E. Intercepting Filter

3. Your company wants to leverage its distributed silos. Your job is to seamlessly integrate your application’s web service endpoints with its DAOs. In addition, your coarse-grained Controller Locators must be enhanced to support J2ME, UDDI registries.
   Which design pattern can be used to achieve these design requirements?
   - A. Domain Activator
   - B. Intercepting Observer
   - C. Composite Delegate
   - D. Transfer Facade
This statement describes the potential benefits of a design pattern:

The pattern reduces network roundtrips between a client and an Enterprise Bean, and gives the client a local copy of the data encapsulated by an Enterprise Bean after a single method call, instead of requiring several method calls. Which design pattern is being described?

- A. Transfer object
- B. Intercepting Filter
- C. Model-View-Controller
- D. Business Delegate

Your company, Models 'R Us, is creating an advanced inventory maximization component that can be used with all major J2EE container vendors. Your job is to design the piece of this component that will perform JNDI lookups with whatever vendor the client is using.

What design pattern can help you accomplish this task?

- A. Transfer object
- B. Intercepting Filter
- C. Model-View-Controller
- D. Business Delegate
- E. Service Locator

While fine tuning your multi-tiered J2EE business application, you’ve discovered that you’d get better performance if you reduced the number of remote requests your app makes, and increased the amount of data collected for each request you make.

What design pattern should you consider to implement this change in your application?

- A. Transfer object
- B. Service Locator
- C. Front Controller
- D. Intercepting Filter
- E. Model-View-Controller
Given this list of attributes:
- related to Service Locator
- reduces coupling
- can add a layer and some complexity

Which design pattern is being described?
- A. Transfer Object
- B. Front Controller
- C. Business Delegate
- D. Intercepting Filter
- E. Model-View-Controller

Your web application uses a SessionBean component in a distributed application to make a specialized calculation, such as validating credit-card numbers. However, you want to shield your web components from the code involved with looking up the SessionBean component and using its interface. You want to decouple local application classes from the looking up and use of the distributed component, whose interface could change. Which J2EE design pattern can you use in this case?
- A. Transfer object.
- B. Service Locator.
- C. Model-View-Controller.
- D. Business Delegate.

Given this list of attributes:
- related to Business Delegate
- improves network performance
- can improve client performance through caching

Which design pattern is being described?
- A. Transfer Object
- B. Service Locator
- C. Front Controller
- D. Intercepting Filter
- E. Model-View-Controller
Given this list of attributes:
- related to Interception Filter
- supports role separation between developers
- adds reusability
Which design pattern is being described?

- A. Transfer Object
- B. Service Locator
- C. Front Controller
- D. Business Delegate

The design of your web application calls for certain security measures to be taken for every request received. Some of these security checks will be applied, regardless of the type of request.

Which design pattern can be used to achieve this design requirement?

- A. Transfer Object
- B. Service Locator
- C. Composite Entity
- D. Business Delegate
- E. Interception Filter

Your company wants to leverage its distributed silos. Your job is to seamlessly integrate your application’s web service endpoints with its DAOs. In addition, your coarse-grained Controller Locators must be enhanced to support J2ME, UDDI registries.

Which design pattern can be used to achieve these design requirements?

- A. Domain Activator

- C. Composite Delegate
- D. Transfer Facade
mock answers

4 This statement describes the potential benefits of a design pattern:
The pattern reduces network roundtrips between a client and an Enterprise Bean, and gives the client a local copy of the data encapsulated by an Enterprise Bean after a single method call, instead of requiring several method calls. Which design pattern is being described?

- A. Transfer object
- B. Interception Filter
- C. Model-View-Controller
- D. Business Delegate

5 Your company, Models ‘R Us, is creating an advanced inventory maximization component that can be used with all major J2EE container vendors. Your job is to design the piece of this component that will perform JNDI lookups with whatever vendor the client is using. What design pattern can help you accomplish this task?

- A. Transfer object
- B. Interception Filter
- C. Model-View-Controller
- D. Business Delegate
- E. Service Locator

6 While fine tuning your multi-tiered J2EE business application, you’ve discovered that you’d get better performance if you reduced the number of remote requests your app makes, and increased the amount of data collected for each request you make. What design pattern should you consider to implement this change in your application?

- A. Transfer object
- B. Service Locator
- C. Front Controller
- D. Interception Filter
- E. Model-View-Controller
Given this list of attributes:
- related to Service Locator
- reduces coupling
- can add a layer and some complexity

Which design pattern is being described?

- A. Transfer Object
- B. Front Controller
- C. Business Delegate
- D. Intercepting Filter
- E. Model-View-Controller

Although a layer is added, the benefits of this pattern (such as reduced coupling and a simpler business tier interface), make it worthwhile.

Your web application uses a SessionBean component in a distributed application to make a specialized calculation, such as validating credit-card numbers. However, you want to shield your web components from the code involved with looking up the SessionBean component and using its interface. You want to decouple local application classes from the looking up and use of the distributed component, whose interface could change. Which J2EE design pattern can you use in this case?

- A. Transfer object.
- B. Service Locator.
- C. Model-View-Controller.
- D. Business Delegate.

A key benefit of the Business Delegate is reduced coupling between the presentation tier and the business tier.

Given this list of attributes:
- related to Business Delegate
- improves network performance
- can improve client performance through caching

Which design pattern is being described?

- A. Transfer Object
- B. Service Locator
- C. Front Controller
- D. Intercepting Filter
- E. Model-View-Controller

By using this pattern you can combine the network calls necessary to lookup and create business objects.
