About the Author

Dr. Barry Burd received an M.S. degree in Computer Science at Rutgers University and a Ph.D. in Mathematics at the University of Illinois. As a teaching assistant in Champaign-Urbana, Illinois, he was elected five times to the university-wide List of Teachers Ranked as Excellent by Their Students.

Since 1980, Dr. Burd has been a professor in the Department of Mathematics and Computer Science at Drew University in Madison, New Jersey. When he’s not lecturing at Drew University, Dr. Burd leads training courses for professional programmers in business and industry. He has lectured at conferences in the United States, Europe, Australia, and Asia. He is the author of several articles and books, including *JSP: JavaServer Pages* and *Beginning Programming with Java For Dummies*, both from Wiley Publishing, Inc.

Dr. Burd lives in Madison, New Jersey, with his wife and two children. In his spare time, he enjoys being a workaholic.

Chapter 10: Putting Variables and Methods
Where They Belong ..............................................................221
Defining a Class (What It Means to Be a Baseball Player) .................222
Another way to beautify your numbers ........................................223
Using the Player class ....................................................................223
Nine, count ’em, nine .....................................................................225
Don’t get all GUI on me ................................................................226
Tossing an exception from method to method ................................227
Making Static (Finding the Team Average) .......................................228
Why is there so much static? ........................................................230
Displaying the overall team average ..............................................231
Static is old hat .............................................................................233
Could cause static; handle with care .........................................234
Experiments with Variables ..........................................................235
Putting a variable in its place ........................................................236
Telling a variable where to go ........................................................238
Passing Parameters .................................................................241
Pass by value .................................................................................241
Returning a result ..........................................................................243
Pass by reference ..........................................................................244
Returning an object from a method ..............................................246
Epilogue .........................................................................................247

Chapter 11: Using Arrays and Collections to Juggle Values .............249
Getting Your Ducks All in a Row ..................................................249
Creating an array in two easy steps ..............................................251
Storing values ..............................................................................252
Tab stops and other special things ..............................................255
Using an array initializer ..............................................................255
Stepping through an array with the enhanced for loop ................256
Searching .....................................................................................257
Arrays of Objects .........................................................................261
Using the Room class ................................................................262
Yet another way to beautify your numbers ...................................265
The conditional operator ...............................................................266
Looking for Java Jobs .................................................................315
Becoming Certified in Java ......................................................316
Developing Servlets .................................................................316
Everyone’s Favorite Sites .........................................................316

Part VI: Appendixes ....................................................................319

Appendix A: Using the CD-ROM .................................................321
What You Can Expect to Find on the CD-ROM .......................321
System Requirements ..............................................................322
Using the CD with Microsoft Windows .................................323
Using the CD with Mac OS .......................................................324
Running the Java Code That’s in This Book ..........................325
Freeware, Shareware, and Just Plain Ware ..............................326
  JCreator .................................................................326
  Adobe Acrobat Reader ......................................................327
  Jindent ........................................................................327
  NetCaptor .....................................................................328
  WinOne ........................................................................328
And, If You Run into Any Trouble ........................................328

Appendix B: When to Use Words Like “public” and “private” ....331
Members versus Classes ........................................................331
Access Modifiers for Members ..............................................332
  Default access ..........................................................334
  Protected access .......................................................334
Access Modifiers for Classes .................................................338

Introduction

Java is good stuff. I’ve been using it for years. I like Java because it’s very orderly. Almost everything follows simple rules. The rules can seem intimidating at times, but this book is here to help you figure them out. So, if you want to use Java and want an alternative to the traditional techie, soft-cover book, sit down, relax, and start reading *Java 2 For Dummies, 2nd Edition*.

How to Use This Book

I wish I could say, “Open to a random page of this book and start writing Java code. Just fill in the blanks and don’t look back.” In a sense, this is true. You can’t break anything by writing Java code, so you’re always free to experiment.

But let me be honest. If you don’t understand the bigger picture, writing a program is difficult. That’s true with any computer programming language — not just Java. If you’re typing code without knowing what it’s about, and the code doesn’t do exactly what you want it to do, you’re just plain stuck.

So, in this book, I divide Java programming into manageable chunks. Each chunk is (more or less) a chapter. You can jump in anywhere you want — Chapter 5, Chapter 10, or wherever. You can even start by poking around in the middle of a chapter. I’ve tried to make the examples interesting without making one chapter depend on another. When I use an important idea from another chapter, I include a note to help you find your way around.

In general, my advice is as follows:

- If you already know something, don’t bother reading about it.
- If you’re curious, don’t be afraid to skip ahead. You can always sneak a peek at an earlier chapter if you really need to do so.

Conventions Used in This Book

Almost every technical book starts with a little typeface legend, and *Java 2 For Dummies, 2nd Edition*, is no exception. What follows is a brief explanation of the typefaces used in this book:
New terms are set in *italics*.

If you need to type something that’s mixed in with the regular text, the characters you type appear in bold. For example: “Type **MyNewProject** in the text field.”

You also see this **computerese** font. I use computerese for Java code, filenames, Web page addresses (URLs), on-screen messages, and other such things. Also, if something you need to type is really long, it appears in computerese font on its own line (or lines).

You need to change certain things when you type them on your own computer keyboard. For instance, I may ask you to type

```
public class Anyname
```

which means that you type **public class** and then some name that you make up on your own. Words that you need to replace with your own words are set in *italicized computerese*.

---

**What You Don’t Have to Read**

Pick the first chapter or section that has material you don’t already know and start reading there. Of course, you may hate making decisions as much as I do. If so, here are some guidelines that you can follow:

- If you already know what kind of an animal Java is and know that you want to use Java, skip Chapter 1 and go straight to Chapter 2. Believe me, I won’t mind.

- If you already know how to get a Java program running, skip Chapter 2 and start with Chapter 3.

- If you write programs for a living but use any language other than C or C++, start with Chapter 2 or 3. When you reach Chapters 5 and 6, you’ll probably find them to be easy reading. When you get to Chapter 7, it’ll be time to dive in.

- If you write C (not C++) programs for a living, start with Chapters 3 and 4 but just skim Chapters 5 and 6.

- If you write C++ programs for a living, glance at Chapter 3, skim Chapters 4 through 6, and start reading seriously in Chapter 7. (Java is a bit different from C++ in the way it handles classes and objects.)

- If you write Java programs for a living, come to my house and help me write *Java 2 For Dummies*, 3rd Edition.

If you want to skip the sidebars and the Technical Stuff icons, please do. In fact, if you want to skip anything at all, feel free.
Foolish Assumptions

In this book, I make a few assumptions about you, the reader. If one of these assumptions is incorrect, you’re probably okay. If all these assumptions are incorrect . . . well, buy the book anyway.

✓ I assume that you have access to a computer. Here’s the good news: You can run the code in this book on almost any computer. The only computers that you can’t use to run this code are ancient things that are more than six years old (give or take a few years).

✓ I assume that you can navigate through your computer’s common menus and dialog boxes. You don’t have to be a Windows, Unix, or Macintosh power user, but you should be able to start a program, find a file, put a file into a certain directory . . . that sort of thing. Most of the time, when you practice the stuff in this book, you’re typing code on your keyboard, not pointing and clicking your mouse.

On those rare occasions when you need to drag and drop, cut and paste, or plug and play, I guide you carefully through the steps. But your computer may be configured in any of several billion ways, and my instructions may not quite fit your special situation. So, when you reach one of these platform-specific tasks, try following the steps in this book. If the steps don’t quite fit, consult a book with instructions tailored to your system.

✓ I assume that you can think logically. That’s all there is to programming in Java — thinking logically. If you can think logically, you’ve got it made. If you don’t believe that you can think logically, read on. You may be pleasantly surprised.

✓ I make very few assumptions about your computer programming experience (or your lack of such experience). In writing this book, I’ve tried to do the impossible. I’ve tried to make the book interesting for experienced programmers, yet accessible to people with little or no programming experience. This means that I don’t assume any particular programming background on your part. If you’ve never created a loop or indexed an array, that’s okay.

On the other hand, if you’ve done these things (maybe in Visual Basic, COBOL, or C++), you’ll discover some interesting plot twists in Java. The developers of Java took the best ideas in object-oriented programming, streamlined them, reworked them, and reorganized them into a sleek, powerful way of thinking about problems. You’ll find many new, thought-provoking features in Java. As you find out about these features, many of them will seem very natural to you. One way or another, you’ll feel good about using Java.
How This Book Is Organized

This book is divided into subsections, which are grouped into sections, which come together to make chapters, which are lumped finally into six parts. (When you write a book, you get to know your book’s structure pretty well. After months of writing, you find yourself dreaming in sections and chapters when you go to bed at night.) The parts of the book are listed here.

Part I: Getting Started

This part is your complete executive briefing on Java. It includes a “What is Java?” chapter and a complete set of instructions on installing and running Java. It also has a jump-start chapter — Chapter 3. In this chapter, you visit the major technical ideas and dissect a simple program.

Part II: Writing Your Own Java Programs

Chapters 4 through 6 cover the basic building blocks. These chapters describe the things that you need to know so you can get your computer humming along.

If you’ve written programs in Visual Basic, C++, or any another language, some of the material in Part II may be familiar to you. If so, you can skip some sections or read this stuff quickly. But don’t read too quickly. Java is a little different from some other programming languages, especially in the things that I describe in Chapter 4.

Part III: Working with the Big Picture: Object-Oriented Programming

Part III has some of my favorite chapters. This part covers the all-important topic of object-oriented programming. In these chapters, you find out how to map solutions to big problems. (Sure, the examples in these chapters aren’t big, but the examples involve big ideas.) In bite-worthy increments, you discover how to design classes, reuse existing classes, and construct objects.

Have you read any of those books that explain object-oriented programming in vague, general terms? I’m very proud to say that Java 2 For Dummies, 2nd Edition, isn’t like that. In this book, I illustrate each concept with a simple-yet-concrete program example.
Part IV: Savvy Java Techniques

If you’ve tasted some Java and want more, you can find what you need in this part of the book. This part’s chapters are devoted to details — the things that you don’t see when you first glance at the material. So, after you read the earlier parts and write some programs on your own, you can dive in a little deeper by reading Part IV.

Part V: The Part of Tens

The Part of Tens is a little Java candy store. In the Part of Tens, you can find lists — lists of tips for avoiding mistakes, resources, and all kinds of interesting goodies.

Part VI: Appendixes

The book has two appendixes. One appendix tells you all about this book’s CD-ROM (what’s on the CD, how to use the CD, how to make the CD look like a UFO at night, and so on). The other appendix summarizes some important rules for writing Java programs. To find out which parts of your code spill over automatically into other peoples’ code, read the second appendix.

Bonus Chapters on the CD-ROM!

You’ve read the Java 2 For Dummies book, seen the Java 2 For Dummies movie, worn the Java 2 For Dummies T-shirt, and eaten the Java 2 For Dummies candy. What more is there to do?

That’s easy. Just pop in the book’s CD-ROM and you can find four additional chapters:

✔️ In Chapter 15, you combine several smaller programs to create a bigger program. As part of that process, you find out which parts of one program are of use to any other program. You get an expanded description of the material in Appendix B.

✔️ In Chapter 16, you handle button clicks, keystrokes, and other such things. You find out about one additional Java language feature (something like a Java class) called an interface.
In Chapter 17, you deal with Java applets. You put applets on Web pages, draw things, and make things move. You create a small game that visitors to your site can play.

In Chapter 18, you see an example of Java database handling. The example takes you from start to finish — from establishing a connection and creating a table to adding rows and making queries.

Note: For you Web fanatics out there, you can also read the bonus chapters on the Web at www.dummies.com/go/java2_fd.

Icons Used in This Book

If you could watch me write this book, you'd see me sitting at my computer, talking to myself. I say each sentence in my head. Most of the sentences I mutter several times. When I have an extra thought, a side comment, or something that doesn't belong in the regular stream, I twist my head a little bit. That way, whoever's listening to me (usually nobody) knows that I'm off on a momentary tangent.

Of course, in print, you can't see me twisting my head. I need some other way of setting a side thought in a corner by itself. I do it with icons. When you see a Tip icon or a Remember icon, you know that I'm taking a quick detour.

Here's a list of icons that I use in this book.

A tip is an extra piece of information — something helpful that the other books may forget to tell you.

Everyone makes mistakes. Heaven knows that I've made a few in my time. Anyway, when I think people are especially prone to make a mistake, I mark it with a Warning icon.

Question: What's stronger than a Tip, but not as strong as a Warning?

Answer: A Remember icon.

"If you don't remember what such-and-such means, see blah-blah-blah," or "For more information, read blahbity-blah-blah."
This icon calls attention to useful material that you can find online. (You don’t have to wait long to see one of these icons. I use one at the end of this introduction!)

I use this icon to point out useful stuff that’s on the CD (obviously).

Occasionally I run across a technical tidbit. The tidbit may help you understand what the people behind the scenes (the people who developed Java) were thinking. You don’t have to read it, but you may find it useful. You may also find the tidbit helpful if you plan to read other (more geeky) books about Java.

Where to Go from Here

If you’ve gotten this far, you’re ready to start reading about Java. Think of me (the author) as your guide, your host, your personal assistant. I do everything I can to keep things interesting and, most importantly, help you understand.

If you like what you read, send me a note. My e-mail address, which I created just for comments and questions about this book, is Java2ForDummies@BurdBrain.com. And don’t forget — for the latest updates, visit one of this book’s support Web sites. The support sites’ addresses are www.BurdBrain.com and www.dummies.com/go/java2_fd.
Part I
Getting Started

The 5th Wave
By Rich Tennant

Honey, please! You’ll upset BOB.
In this part . . .

Become acquainted with Java. Find out what Java is all about, and whether you do (or don’t) want to use Java. If you’ve heard things about Java and aren’t sure what they mean, the material in this part can help you. If you’re staring at your computer, wondering how you’re going to get a Java program running, this part has the information that you need. Maybe you’ve told people that you’re a Java expert, and now you need to do some serious bluffing. If so, this part of the book is your crash course in Java. (Of course, if the word bluffing describes you accurately, you may also want to pick up a copy of Ethics For Dummies.)
Chapter 1

All about Java

In This Chapter
- What Java is
- Where Java came from
- Why Java is so cool
- How to orient yourself to object-oriented programming

Say what you want about computers. As far as I’m concerned, computers are good for just two simple reasons:

✓ **When computers do work, they feel no resistance, no stress, no boredom, and no fatigue.** Computers are our electronic slaves. I have my computer working 24/7 doing calculations for SETI@home — the search for extraterrestrial intelligence. Do I feel sorry for my computer because it’s working so hard? Does the computer complain? Will the computer report me to the National Labor Relations Board? No.

I can make demands, give the computer its orders, and crack the whip. Do I (or should I) feel the least bit guilty? Not at all.

✓ **Computers move ideas, not paper.** Not long ago, when you wanted to send a message to someone, you hired a messenger. The messenger got on his or her horse and delivered your message personally. The message was on paper, parchment, a clay tablet, or whatever physical medium was available at the time.

This whole process seems wasteful now, but that’s only because you and I are sitting comfortably at the dawn of the electronic age. The thing is that messages are ideas. Physical things like ink, paper, and horses have little or nothing to do with real ideas. These physical things are just temporary carriers for ideas (temporary because people used them to carry ideas for several centuries). But, in truth, the ideas themselves are paperless, horseless, and messengerless.

So the neat thing about computers is that they carry ideas efficiently. They carry nothing but the ideas, a couple of photons, and a little electrical power. They do this with no muss, no fuss, and no extra physical baggage.
When you start dealing efficiently with ideas, something very nice happens. Suddenly, all the overhead is gone. Instead of pushing paper and trees, you’re pushing numbers and concepts. Without the overhead, you can do things much faster and do things that are far more complex than ever before.

**What You Can Do with Java**

It would be so nice if all this complexity was free, but unfortunately, it isn’t. Someone has to think hard and decide exactly what the computer will be asked to do. After that thinking is done, someone has to write a set of instructions for the computer to follow.

Given the current state of affairs, you can’t write these instructions in English or any other language that people speak. Science fiction is filled with stories about people who say simple things to robots and get back disastrous, unexpected results. English and other such languages are unsuitable for communication with computers for several reasons:

- **An English sentence can be misinterpreted.** “Chew one tablet three times a day until finished.”
- **It’s difficult to weave a very complicated command in English.** “Join flange A to protuberance B, making sure to connect only the outermost lip of flange A to the larger end of the protuberance B, while joining the middle and inner lips of flange A to grommet C.”
- **An English sentence has lots of extra baggage.** “Sentence has unneeded words.”
- **English is difficult to interpret.** “As part of this Publishing Agreement between John Wiley & Sons, Inc. (‘Wiley’) and the Author (‘Barry Burd’), Wiley shall pay the sum of one-thousand-two-hundred-fifty-seven dollars and sixty-three cents ($1,257.63) to the Author for partial submittal of *Java 2 For Dummies, 2nd Edition* (‘the Work’).”

To tell a computer what to do, you have to speak a special language and write terse, unambiguous instructions in that language. A special language of this kind is called a *computer programming language*. A set of instructions, written in such a language, is called a *program*. When they’re looked at as a big blob, these instructions are called *software* or *code*. Here’s what code looks like when it’s written in Java:

```java
import static java.lang.System.out;

class PayBarry {
    public static void main(String args[]) {
```
Why You Should Use Java

It’s time to celebrate! You’ve just picked up a copy of Java 2 For Dummies, 2nd Edition, and you’re reading Chapter 1. At this rate, you’ll be an expert Java programmer in no time at all, so rejoice in your eventual success by throwing a big party.

To prepare for the party, I’ll bake a cake. I’m lazy, so I’ll use a ready-to-bake cake mix. Let me see . . . add water to the mix, and then add butter and eggs . . . Hey, wait! I just looked at the list of ingredients. What’s MSG? And what about propylene glycol? That’s used in antifreeze, isn’t it?

I’ll change plans and make the cake from scratch. Sure, it’s a little harder. But that way, I get exactly what I want.

Computer programs work the same way. You can use somebody else’s program or write your own. If you use somebody else’s program, you use whatever you get. When you write your own program, you can tailor the program especially for your needs.

Writing computer code is a big, worldwide industry. Companies do it, freelance professionals do it, hobbyists do it, all kinds of people do it. A typical big company has teams, departments, and divisions that write programs for the company. But you can write programs for yourself or someone else, for a living or for fun. In a recent estimate, the number of lines of code written each day by programmers in the United States alone exceeds the number of methane molecules on the planet Jupiter.* Take almost anything that can be done with a computer. With the right amount of time, you can write your own program to do it. (Of course, the “right amount of time” may be very long, but that’s not the point. Many interesting and useful programs can be written in hours or even minutes.)

* I made up this statistic all by myself.
Getting Perspective: Where Java Fits In

Here’s a brief history of modern computer programming:

- **1954–1957: FORTRAN is developed.**
  
  FORTRAN was the first modern computer programming language. For scientific programming, FORTRAN is a real racehorse. Year after year, FORTRAN is a leading language among computer programmers throughout the world. A well-known computer scientist, Tony Hoare, once said, “I don’t know what the language of the year 2000 will look like, but I know it will be called FORTRAN.”

- **1959: COBOL is created.**
  
  The letter B in COBOL stands for Business, and business is just what COBOL is all about. The language’s primary feature is the processing of one record after another, one customer after another, or one employee after another.

  Within a few years after its initial development, COBOL became the most widely used language for business data processing. Even today, COBOL represents a large part of the computer programming industry.

- **1972: Dennis Ritchie at AT&T Bell Labs develops the C programming language.**
  
  The look and feel that you see in this book’s examples come from the C programming language. Code written in C uses curly braces, if statements, for statements, and so on.

  In terms of power, you can use C to solve the same problems that you can solve by using FORTRAN, Java, or any other modern programming language. (You can write a scientific calculator program in COBOL, but doing that sort of thing would feel really strange.) The difference between one programming language and another isn’t power. The difference is ease and appropriateness of use. That’s where the Java language excels.

- **1986: Bjarne Stroustrup (again at AT&T Bell Labs) develops C++.**
  
  Unlike its C language ancestor, the language C++ supports object-oriented programming. This represents a huge step forward.

- **May 23, 1995: Sun Microsystems releases its first official version of the Java programming language.**
  
  Java improves upon the concepts in C++. Unlike C++, Java is streamlined for use on the World Wide Web. Java’s “Write Once, Run Anywhere” philosophy makes the language ideal for distributing code across the Internet.
In addition, Java is a great general-purpose programming language. With Java, you can write windowed applications, build and explore databases, control handheld devices, and more. Within five short years, the Java programming language had 2.5 million developers worldwide. (I know. I have a commemorative T-shirt to prove it.)

**November 2000:** The College Board announces that, starting in the year 2003, the Computer Science Advanced Placement exams will be based on Java.

Wanna know what that snot-nosed kid living down the street is going to be learning in high school next year? You guessed it — Java.

**March 2003:** SkillMarket (mshiltonj.com/sm) reports that the demand for Java programmers tops the demand for C++ programmers by 42 percent.

And there’s more! The demand for Java programmers beats the combined demand for C++ and C# programmers by 10 percent. Java programmers are more employable than VB (Visual Basic) programmers by a whopping 111 percent.

---

**Object-Oriented Programming (OOP)**

It’s three in the morning. I’m dreaming about the history course that I failed in high school. The teacher is yelling at me, “You have two days to study for the final exam, but you won’t remember to study. You’ll forget and feel guilty, guilty, guilty.”

Suddenly, the phone rings. I’m awakened abruptly from my deep sleep. (Sure, I disliked dreaming about the history course, but I like being awakened even less.) At first, I drop the telephone on the floor. After fumbling to pick it up, I issue a grumpy, “Hello, who’s this?” A voice answers, “I’m a reporter from *The New York Times*. I’m writing an article about Java and I need to know all about the programming language in five words or less. Can you explain it?”

My mind is too hazy. I can’t think. So I say anything that comes to my mind, and then go back to sleep.

Come morning, I hardly remember the conversation with the reporter. In fact, I don’t remember how I answered the question. Did I tell the reporter where he could put his article about Java?

I put on my robe and rush to the front of my house’s driveway. As I pick up the morning paper, I glance at the front page and see the two-inch headline:

**Burd Calls Java “A Great Object-Oriented Language”**
Object-oriented languages

Java is object-oriented. What does that mean? Unlike languages such as FORTRAN, which focus on giving the computer imperative “Do this/Do that” commands, object-oriented languages focus on data. Of course, object-oriented programs still tell the computer what to do. You start, however, by organizing the data, and the commands come later.

Object-oriented languages are better than “Do this/Do that” languages because they organize data in a way that lets people do all kinds of things with it. To modify the data, you can build on what you already have, rather than scrap everything you’ve done and start over each time you need to do something new. Although computer programmers are generally smart people, they took awhile to figure this out. For the full history lesson, see the sidebar “The winding road from FORTRAN to Java” (but I won’t make you feel guilty if you don’t read it).

The winding road from FORTRAN to Java

Back in the mid-1950s, a team of people created a programming language named FORTRAN. It was a good language, but it was based on the idea that you should issue direct, imperative commands to the computer. “Do this, computer. Then do that, computer.” (Of course, the commands in a real FORTRAN program were much more precise than “Do this” or “Do that.”)

In the years that followed, teams developed many new computer languages, and many of the languages copied the FORTRAN “Do this/Do that” model. One of the more popular “Do this/Do that” languages went by the one-letter name C. Of course, the “Do this/Do that” camp had some renegades. In languages named SIMULA and Smalltalk, programmers moved the imperative “Do this” commands into the background and concentrated on descriptions of data. In these languages, you didn’t come right out and say, “Print a list of delinquent accounts.” Instead, you began by saying, “This is what it means to be an account. An account has a name and a balance.” Then you said, “This is how you ask an account whether it’s delinquent.” Suddenly, the data became king. An account was a thing that had a name, a balance, and a way of telling you whether it was delinquent.

Languages that focus first on the data are called object-oriented programming languages. These object-oriented languages make excellent programming tools. Here’s why:

- Thinking first about the data makes you a good computer programmer.
- You can extend and reuse the descriptions of data over and over again. When you try to teach old FORTRAN programs new tricks, however, the old programs show how brittle they are. They break.

In the 1970s, object-oriented languages like SIMULA and Smalltalk became buried in the computer hobbyist magazine articles. In the meantime, languages based on the old FORTRAN model were multiplying like rabbits.
Objects and their classes

In an object-oriented language, you use objects and classes to organize your data.

Imagine that you’re writing a computer program to keep track of the houses in a new real-estate development. The development (still under construction) is a condominium. The houses differ only slightly from one another. Each house has a distinctive siding color, an indoor paint color, a kitchen cabinet style, and so on. In your object-oriented computer program, each house is an object.

But objects aren’t the whole story. Although the houses differ slightly from one another, all the houses share the same list of characteristics. For instance, each house has a characteristic known as siding color. Each house has another characteristic known as kitchen cabinet style. In your object-oriented program, you need a master list containing all the characteristics that a house object can possess. This master list of characteristics is called a class.

So there you have it. Object-oriented programming is misnamed. It should really be called “programming with classes and objects.”
Now notice that I put the word classes first. How dare I do this! Well, maybe I’m not so crazy. Think again about a housing development that’s under construction. Somewhere on the lot, in a rickety trailer parked on bare dirt, is a master list of characteristics known as a blueprint. An architect’s blueprint is like an object-oriented programmer’s class. A blueprint is a list of characteristics that each house will have. The blueprint says, “siding.” The actual house object has gray siding. The blueprint says, “kitchen cabinet.” The actual house object has Louis XIV kitchen cabinets.

The analogy doesn’t end with lists of characteristics. Another important parallel exists between blueprints and classes. A year after you create the blueprint, you use it to build ten houses. It’s the same with classes and objects. First, the programmer writes code to describe a class. Then when the program runs, the computer creates objects from the (blueprint) class.

So that’s the real relationship between classes and objects. The programmer defines a class, and from the class definition, the computer makes individual objects.

\textbf{What’s so good about an object-oriented language?}

Based on the previous section’s story about home building, imagine that you have already written a computer program to keep track of the building instructions for houses in a new development. Then, the big boss decides on a modified plan — a plan in which half the houses have three bedrooms, and the other half have four.

If you use the old FORTRAN/C style of computer programming, your instructions look like this:

\begin{verbatim}
Dig a ditch for the basement.
Lay concrete around the sides of the ditch.
Put two-by-fours along the sides for the basement's frame.
...
\end{verbatim}

This would be like an architect creating a long list of instructions instead of a blueprint. To modify the plan, you would have to sort through the list to find the instructions for building bedrooms. To make things worse, the instructions could be scattered among pages 234, 394–410, 739, 10, and 2. If the builder had to decipher other peoples’ complicated instructions, the task would be ten times harder.

Starting with a class, however, is like starting with a blueprint. If someone decides to have both three- and four-bedroom houses, you can start with a blueprint called the \textit{house} blueprint that has a ground floor and a second
floor, but has no indoor walls drawn on the second floor. Then, you make two more second-floor blueprints — one for the three-bedroom house and another for the four-bedroom house. (You name these new blueprints the three-bedroom house blueprint and the four-bedroom house blueprint.)

Your builder colleagues are amazed with your sense of logic and organization, but they have concerns. They pose a question. “You called one of the blueprints the ‘three-bedroom house’ blueprint. How can you do this if it’s a blueprint for a second floor, and not for a whole house?”

You smile knowingly and answer, “The three-bedroom house blueprint can say, ‘For info about the lower floors, see the original house blueprint.’ That way, the three-bedroom house blueprint describes a whole house. The four-bedroom house blueprint can say the same thing. With this setup, we can take advantage of all the work we already did to create the original house blueprint and save lots of money.”

In the language of object-oriented programming, the three- and four-bedroom house classes are inheriting the features of the original house class. You can also say that the three- and four-bedroom house classes are extending the original house class. (See Figure 1-1.)

The original house class is called the superclass of the three- and four-bedroom house classes. In that vein, the three- and four-bedroom house classes are subclasses of the original house class. Put another way, the original house class is called the parent class of three- and four-bedroom house classes. The three- and four-bedroom house classes are child classes of the original house class. (See Figure 1-1.)

---

**Figure 1-1: Terminology in object-oriented programming.**

- **Superclass Parent**
  - The house class is
    - the superclass of the three-bedroom house class,
    - the parent class of the three-bedroom house class,
    - the superclass of the four-bedroom house class,
    - the parent class of the four-bedroom house class.

- **Subclass Child**
  - The three-bedroom house class
    - extends the house class,
    - inherits the features of the house class,
    - is a subclass of the house class,
    - is a child class of the house class.

- **Subclass Child**
  - The four-bedroom house class
    - extends the house class,
    - inherits the features of the house class,
    - is a subclass of the house class,
    - is a child class of the house class.
Needless to say, your home-builder colleagues are jealous. A crowd of home-builders is mobbing around you to hear about your great ideas. So, at that moment, you drop one more bombshell: “By creating a class with subclasses, we can reuse the blueprint in the future. If someone comes along and wants a five-bedroom house, we can extend our original house blueprint by making a five-bedroom house blueprint. We’ll never have to spend money for an original house blueprint again.”

“But,” says a colleague in the back row, “what happens if someone wants a different first-floor design? Do we trash the original house blueprint or start scribbling all over the original blueprint? That’ll cost big bucks, won’t it?”

In a confident tone, you reply, “We don’t have to mess with the original house blueprint. If someone wants a Jacuzzi in his living room, we can make a new, small blueprint describing only the new living room and call this the Jacuzzi-in-living-room house blueprint. Then, this new blueprint can refer to the original house blueprint for info on the rest of the house (the part that’s not in the living room).” In the language of object-oriented programming, the Jacuzzi-in-living-room house blueprint still extends the original house blueprint. The Jacuzzi blueprint is still a subclass of the original house blueprint. In fact, all the terminology about superclass, parent class, and child class still applies. The only thing that’s new is that the Jacuzzi blueprint overrides the living room features in the original house blueprint.

In the days before object-oriented languages, the programming world experienced a crisis in software development. Programmers wrote code, then discovered new needs, and then had to trash their code and start from scratch. This happened over and over again because the code that the programmers were writing couldn’t be reused. Object-oriented programming changed all this for the better (and, as Burd said, Java is “A Great Object-Oriented Language”).

**Refining your understanding of classes and objects**

When you program in Java, you work constantly with classes and objects. These two ideas are really important. That’s why, in this chapter, I hit you over the head with one analogy after another about classes and objects.

Close your eyes for a minute and think about what it means for something to be a chair. . . .

A chair has a seat, a back, and legs. Each seat has a shape, a color, a degree of softness, and so on. These are the properties that a chair possesses. What I
describe is chairness — the notion of something being a chair. In object-oriented terminology, I’m describing the chair class.

Now peek over the edge of this book’s margin and take a minute to look around your room. (If you’re not sitting in a room right now, fake it.)

Several chairs are in the room, and each chair is an object. Each of these objects is an example of that ethereal thing called the Chair class. So that’s how it works — the class is the idea of chairness, and each individual chair is an object.

A class isn’t quite a collection of things. Instead, a class is the idea behind a certain kind of thing. When I talk about the class of chairs in your room, I’m talking about the fact that each chair has legs, a seat, a color, and so on. The colors may be different for different chairs in the room, but that doesn’t matter. When you talk about a class of things, you’re focusing on the properties that each of the things possesses.

It makes sense to think of an object as being a concrete instance of a class. In fact, the official terminology is consistent with this thinking. If you write a Java program in which you define a Chair class, each actual chair (the chair that you’re sitting on, the empty chair right next to you, and so on) is called an instance of the Chair class.

Here’s another way to think about a class. Imagine a table displaying all three of your bank accounts. (See Table 1-1.)

<table>
<thead>
<tr>
<th>Account Number</th>
<th>Type</th>
<th>Balance</th>
</tr>
</thead>
<tbody>
<tr>
<td>16-13154-22864-7</td>
<td>Checking</td>
<td>174.87</td>
</tr>
<tr>
<td>1011 1234 2122 0000</td>
<td>Credit</td>
<td>-471.03</td>
</tr>
<tr>
<td>16-17238-13344-7</td>
<td>Savings</td>
<td>247.38</td>
</tr>
</tbody>
</table>

Think of the table’s column headings as a class, and think of each row of the table as an object. The table’s column headings describe the Account class.

According to the table’s column headings, each account has an account number, a type, and a balance. Rephrased in the terminology of object-oriented programming, each object in the Account class (that is, each instance of the Account class) has an account number, a type, and a balance. So, the bottom row of the table is an object with account number
16-17238-13344-7. This same object has type *Savings* and a balance of 247.38. If you opened a new account, you would have another object, and the table would grow an additional row. The new object would be an instance of the same *Account* class.

**What’s Next?**

This chapter is filled with general descriptions of things. A general description is good when you’re just getting started, but you don’t really understand things until you get to know some specifics. That’s why the next several chapters deal with specifics.

So please, turn the page. The next chapter can’t wait for you to read it.
Chapter 2

Running Canned Java Programs

In This Chapter
- Setting up your computer to run Java
- Running text-based programs
- Running window-based programs
- Running Java applets

The best way to get to know Java is to do Java. When you’re doing Java, you’re writing, testing, and running your own Java programs. This chapter gets you ready to do Java by having you run and test programs. Instead of writing your own programs, however, you get to run programs I’ve already written for you — nice guy that I am.

Downloading and Installing the Java Software Development Kit (SDK)

First you need some Java development software. You can choose from several products. In fact, you may already have one of these products on your own computer. If you don’t, you can download the basic software by visiting a Sun Microsystems Web site. The product that you want to download is known by a few different names. It’s called the Java 2 Software Development Kit (SDK), the Java Development Kit (JDK), and the Java 2 Standard Edition (J2SE).

This section tells you how to download and install the Java SDK. First, I give a condensed, quick-start set of instructions. Then, I present a detailed, read-every-step-carefully version.
So what follows is the condensed, quick-start version of instructions for use with Microsoft Windows systems. If these instructions are too condensed for you, follow the detailed instructions that come immediately after these quick instructions.

If you’re using Linux, Unix, Macintosh, or some other non-Windows system, visit this book’s Web site for further instructions.

2. Find a link to download the J2SE 5.0 (the Java 2 Standard Edition, version 5.0).

   If you find some other 1.5.x version, like 1.5.1._02, that’s fine. Just make sure that you have a version numbered 1.5.something-or-other or higher.

3. Download the SDK, not the JRE.

   The JRE (Java Runtime Environment) isn’t harmful to your computer, but the JRE isn’t enough. To create your own Java programs, you need more than the JRE. You need the entire SDK. (Besides, when you run the install program for the SDK, the install program offers to put both the SDK and the JRE on your computer.)

4. Double-click the icon of the downloaded file and follow the wizard’s instructions for installing the Java SDK.

   As the installation begins, the wizard asks you to choose from among several components that can possibly be installed. You can choose to have some or all of the components installed. Just make sure that your choice includes the development tools and the JRE.

   You also see the name of the directory in which the Java SDK is to be installed. Jot down the exact name of the directory. It’s something like jdk1.5 or C:\Program Files\Java\jdk1.5. (For some Java versions, the name starts with j2sdk.) Whatever the directory’s name is, I call this your Java home directory.

   At some point, the wizard asks whether you want to register your Web browser with the latest Java plug-in. If you plan to create Java applets, accept this option and register your browser. (Even if you won’t be writing applets, it’s a good idea to register your browser.)

5. Return to the page where you found the SDK download. Get another download — the J2SE Documentation (also known as the J2SE API Documentation).

6. Extract the zipped J2SE Documentation to your Java home directory.

   Your Java home directory comes with several subdirectories — bin, jre, lib, and a few others. After the extraction, your Java home directory has a new directory named docs. I call this new directory your Javadoc directory.
Downloading Java

If the previous instructions are too quick for you, you can follow this section’s detailed instructions.

The Sun Microsystems Web site changes from week to week. By the time you read this book, my detailed instructions may be obsolete. So as you read these instructions, be ready for some surprises. Be prepared to do some hunting on Sun’s Java Web site. Expect to find a few options that were added to the site after I wrote this chapter. If you get lost, check this book’s Web site for more up-to-date instructions.

Here are the detailed instructions for downloading the Java SDK:

2. On the java.sun.com home page’s right margin, look for something called Popular Downloads.
3. Under Popular Downloads, look for a J2SE 5.0 link.
   The next thing you see is a page full of download links.
   Most of the programs in this book run only under Java 1.5.0 beta, or later. They do not run under any version earlier than Java 1.5.0 beta. In particular, they do not run under Java 1.4 or under Java 1.4.2.
4. Take a few minutes to examine the download links.
   Depending on what Sun Microsystems has cooking when you visit the Web site, you may find variations on the simple J2SE link. You may see the word Platform and the abbreviations SDK and JRE. You also see version numbers, such as 5.0. You want the highest version number that’s available at the Web site.
   Avoid links that are labeled JRE because they lead to the software for running existing Java programs, not the software for writing new Java programs. It’s not bad to have the JRE on your computer, but in order to write new Java programs, you need something more powerful than the JRE. You need the SDK. (In fact, when you download the SDK, you get the JRE along with the SDK. So don’t download the JRE separately.)
5. Click the link to download the latest version of the SDK.
   At java.sun.com, you can find downloads for Windows, Linux, and Solaris. If your favorite operating environment isn’t Windows, Linux, or Solaris, don’t despair. Many third-party vendors have converted Java to other environments. If the Mac is your thing, visit developer.apple.com/java.
   Clicking the SDK download link brings you to the Sun Microsystems License Agreement page.
6. **Do whatever you normally do with license agreements.**

   I won’t be the one to tell you not to bother reading it. If you accept the agreement, you’re taken to yet another Web page.

7. **On this final Web page, click the link or button to start the download.**

   For Windows, the Web page offers two kinds of installation downloads — the regular (online) installation and the offline installation. I prefer the offline installation, but you may prefer the online installation.

   - **The online installation is good if you want to save space on your hard drive.**

     Clicking the online installation link puts a tiny file on your hard drive. Eventually, your hard drive has one tiny file plus the installed Java SDK.

   - **The offline installation is good if you ever want to reinstall the Java SDK.**

     Clicking the offline installation link downloads a huge setup file on your hard drive. Eventually, your hard drive has a huge setup file plus the installed Java SDK.

     The huge setup file takes an extra 50MB on your hard drive, but if you ever want to reinstall Java, you have the setup file right where you need it.

As you begin downloading the tiny online file or the huge offline setup file, note the directory on your hard drive where the file is being deposited.

8. **Return to the Web page that you were visiting in Step 4. On that page, find a link to the J2SE Documentation (also known as the J2SE API Documentation).**

   The Java language has a built-in feature for creating consistent, nicely formatted documentation in Web page format. As a Java programmer, you won’t survive without a copy of the Application Programming Interface (API) documentation by your side. You can bookmark the documentation at the java.sun.com site and revisit the site whenever you need to look up something. But in the long run (and in the not-so-long run), you can save time by downloading your own copy of the API docs.

   See Chapter 3 for more about the API.

9. **Download the API documentation.**

   The documentation comes inside a big Zip file. Just leave this file on your hard drive for now. You don’t unzip the file until you read the next section’s instructions.
Installing Java on your computer

After you download the Java SDK, you’re ready to install the software on your computer. Of course, you can do this 900 different ways, depending on your operating system, the names of directories on your hard drive, the wind velocity, and other factors. The following steps offer some guidelines:

1. Open My Computer and find the SDK file that you downloaded.
   The file has a name like jdk1.5-blah-blah.exe or j2sdk1.5-yada-yada.exe. The exact name depends on the operating system you’re using, the version number that Sun has reached with Java, and whatever naming conventions the people at Sun have changed since book was written.

2. Double-click the SDK file’s icon.
   What happens next depends on which option you chose in Step 7 of the previous set of instructions.
   - If you downloaded the tiny online installation file, your computer downloads more files from the Internet and installs Java while it downloads.
   - If you downloaded the huge offline installation file, your computer extracts the contents of the huge setup file and installs Java from these contents.

3. Among the features that you select to install, make sure you select Development Tools and Public Java Runtime Environment. (See Figure 2-1.)
   You can choose to have some or all of the components installed. Just make sure that your choice includes these two items.

4. Jot down the name of the directory in which the Java SDK is being installed and then click Next.
   From one version to the next, the installation package puts Java in different directories on the computer’s hard drive. Lately the package has installed Java in a directory named C:\Program Files\Java\jdk1.5.0. During the installation on your computer, you may see a different directory name. (One way or another, the name probably has jdk or j2sdk in it.)
   Take note of this directory name when the installation package displays it. (Refer to Figure 2-1.) This directory is called your Java home directory. You need the name of this directory in other sections of this chapter and in other chapters of this book.
If you’re a Windows user, Program Files is probably part of your Java home directory’s name. Whenever I tell you to type the directory’s name, it’s a good idea to type an abbreviated version that doesn’t include the blank space. The official Windows abbreviation for Program Files is progra~1 (with a squiggly little tilde character and 1 at the end). So if my Java home directory is C:\Program Files\Java\jdk1.5.0, then when I need to type the directory’s name, I usually type C:\progra~1\Java\jdk1.5.0.

5. When you see a wizard page that offers to install the Java Web browser plug-in, accept this option and then click Install. (See Figure 2-2.)
Installing the plug-in gives you the ability to run Java applets on your computer.

6. Enjoy the splash screens that you see while the software is being installed.
At the end of the installation, you click the proverbial Finish button. But you’re still not done with the whole kit ‘n caboodle. The next step is installing the Java documentation.

7. Copy the documentation to your Java home directory.
In Step 9 of the previous section, you downloaded a file named jdk-1_5_0-doc.zip (or something like that). Unzip (extract) this file so that its contents are in your Java home directory.
Your Java home directory has a name like `jdk1.5`. That’s not the same as another directory that you may find on your hard drive — a directory with a name like `j2re1.5`.

8. Check to make sure that you unzipped the documentation correctly.

After unzipping the documentation’s Zip file, you should have a subdirectory named `docs` in your Java home directory. So open My Computer and navigate to your new `jdkwhatever` or `j2sdksuch-and-such` folder. Directly inside that folder, you should see a new folder named `docs`. This directory is called your Javadoc directory. (See Figure 2-3.)

When your docs are all lined up in a row, you can proceed to the next step — installing a Java development environment.
Preparing to Use an Integrated Development Environment

If you followed the instructions up to this point, you have all the software that you need for writing and running your own Java programs. But there's one more thing you may want. It's called an **Integrated Development Environment** (IDE). If you don't have an IDE, writing and running a program involves opening several different windows — a window for typing the program, another window for running the program, and maybe a third window to keep track of all the code that you've written. An IDE seamlessly combines all this functionality into one well-organized application.

Java has its share of integrated development environments. Some of the more popular products include Eclipse, Borland JBuilder, NetBeans, and IBM WebSphere. Some fancy environments even have drag-and-drop components so that you can design your graphical interface visually. (See Figure 2-4. For more info on the neat-o Jigloo graphical user interface builder shown here, check out [www.cloudgarden.com/jigloo/index.html](http://www.cloudgarden.com/jigloo/index.html).)
The programs in this book work with almost any Java IDE. But in this chapter, I show you how to use JCreator LE (Lite Edition). I chose JCreator LE over other IDEs for several reasons:

- JCreator LE is free.
- Among all the Java IDEs, JCreator represents a nice compromise between power and simplicity.
- Unlike some other Java IDEs, JCreator works with almost any version of Java, from the ancient version 1.0.2 to the new-and-revolutionary version 5.0.
- JCreator LE is free. (It’s worth mentioning twice.)

If you’re the kind of person who prefers plain old text editors and command prompts over IDEs, visit this book’s Web site. On that site, I’ve posted instructions for writing and running Java programs without an IDE.

This book’s CD-ROM has a special version of JCreator LE — a version that’s customized especially for *Java 2 For Dummies*, 2nd Edition, readers! So please install JCreator LE from the CD-ROM. (Who knows? You may like it a lot, and buy JCreator Pro!)

For help installing materials from the CD-ROM, see Appendix A.

### Running JCreator for the first time

The first time you run JCreator, the program asks for some configuration information. Just follow these steps:

1. **If you haven’t already done so, launch JCreator.**
   
   The JCreator Setup Wizard appears on your screen. The wizard’s first page is for File Associations.

2. **Accept the File Associations defaults and click Next.**
   
   The wizard’s next page (the JDK Home Directory page) appears.

3. **Look at the text field on the JDK Home Directory page. Make sure that this field displays the name of your Java home directory.** (See Figure 2-5.)
If the wrong directory name appears in the text field, just click the Browse button and navigate to your computer’s Java home directory.

For information on your computer’s Java home directory, see Step 4 of this chapter’s “Downloading and Installing the Java Software Development Kit (SDK)” section, or Step 4 of this chapter’s “Installing Java on your computer” section.

4. When you’re happy with the name in the home directory text field, click Next.

The wizard’s last page (the JDK JavaDoc Directory page) appears.

5. Look at the text field on the JDK JavaDoc Directory page. Make sure that this field displays the name of your Javadoc directory. (See Figure 2-6.)
Normally, your Javadoc directory’s name is the name of your Java home directory, followed by \docs. For information on your computer’s Javadoc directory, see Step 6 of this chapter’s “Downloading and Installing the Java Software Development Kit (SDK)” section, or Step 8 of this chapter’s “Installing Java on your computer” section.

If the wrong directory name appears in the text field, just click the Browse button and navigate to your computer’s Javadoc directory.

If you do anything wrong in Steps 3 or 4 above, you can correct your mistake later. See this book’s Web site for details.

6. Click Finish.

At this point, the JCreator work area opens. (See Figure 2-7.)

In JCreator’s help files, the stuff in Figure 2-7 is called the workspace, not the work area. But elsewhere in these help files, JCreator reuses the word workspace to mean something entirely different. To avoid any confusion, I use two different terms. I use work area for the stuff in Figure 2-7, and I use workspace for that other, entirely different thing. (I explain that entirely different thing later in this chapter in the section entitled “Running a text-based program.”)
Running Java Programs

In this section, you run three Java programs — programs I wrote to help you practice running some Java code. Each program computes the monthly payment on a home mortgage, but each program interacts with the user in its own unique way. After you make your way through this section, you’ll know how to run three kinds of programs: a text-based program, a stand-alone GUI program, and a Java applet.

Running a text-based program

The first mortgage-calculating program doesn’t open its own window. Instead, the program runs in JCreator’s General Output pane. (See Figure 2-8.) A program that operates completely in this General Output pane is called a text-based program.

If you’re using Linux, Unix, Mac, or some other non-Windows system, the instructions in this section don’t apply to you. Visit this book’s Web site for an alternative set of instructions.

Actually, as you run the mortgage program, you see two things in the General Output pane:

✔ Messages and results that the mortgage program sends to you. Messages include things like How much are you borrowing? Results include lines like Your monthly payment is $552.20.

✔ Responses that you give to the mortgage program while it runs. If you type 100000.00 in response to the program’s question about how much you’re borrowing, you see that number echoed in the General Output pane.

Running the mortgage program is easy. Here’s how you do it:

1. Make sure that you’ve followed the previous instructions in this chapter — instructions for installing the Java SDK and configuring JCreator.
Thank goodness! You don’t have to follow those instructions more than once.

2. Launch JCreator.

The big JCreator work area stares at you from your computer screen. (Refer to Figure 2-7.)

If this is your first time running JCreator, you don’t see JCreator’s work area. Instead you see the JCreator Setup Wizard. To get past the Setup Wizard, follow the instructions in the section entitled “Running JCreator for the first time” in this chapter.

3. In JCreator’s menu bar, choose File➪Open Workspace from the main menu.

Don’t choose File➪Open. Instead, choose File➪Open Workspace.

A familiar-looking Open dialog box appears. This dialog box looks in your MyProjects directory. This MyProjects directory is a subdirectory of the directory in which JCreator is installed.

The MyProjects directory has subdirectories named Program0201, Listing0302, and so on. The MyProjects directory also has files with names like Chapter02 and Chapter03. If you set your computer so that it doesn’t hide file extensions for known file types, then the names of the files are Chapter02.jcw, Chapter03.jcw, and so on. (See the sidebar entitled “Those pesky filename extensions.”)
4. Select the file named *Chapter02* (or *Chapter02.jcw*), and then click Open.

Clicking Open may coax out a message box asking if you want to “Save the workspace modifications?” If so, click Yes. Clicking Open may coax out another box asking if you want to “...close all document Windows?” If so, click Yes.

JCreator divides things into *workspaces*. Each workspace is further subdivided into *projects*. To organize this book’s examples, I made a workspace for each chapter, and then made a project for each complete Java program. When you open *Chapter02.jcw*, you get my Chapter02 workspace — a workspace that contains three projects. The projects’ names are *Program0201*, *Program0202*, and *Program0203*. That’s why, in JCreator’s File View pane, you see a *Chapter02* tree with branches labeled *Program0201*, *Program0202*, and *Program0203*. (See Figure 2-9.)

5. In the File View’s tree, right-click the branch labeled *Program0201*. In the resulting context menu, choose *Sets as Active Project*. (See Figure 2-9.)

Choosing Sets as Active Project makes *Program0201* the *active project*.
In JCreator, only one project at a time can be the active project. To run a particular program, the program’s code has to be in whatever project is currently active. In JCreator’s File View, you can tell which project is active by looking for the project whose name is boldface. (See Figure 2-9 once again.) On some systems, the active project’s name is a hazy, light-gray boldface.

If a particular program isn’t in the active project, you can’t run that program, but you can do some other things with that program. For instance, you can see the program in one of JCreator’s panes, make changes to the program, save the program, and so on. For this reason, it’s really easy to get confused and forget which project is active. So always keep the active project in the forefront of your mind. If your code doesn’t do what you think it should do, check to make sure that the project you want to run is the active project.

6. Choose Build ➪ Compile Project from the main menu.

Choosing Compile Project does exactly what it says. It compiles the project’s code. (To find out what compile means, see the sidebar entitled “Compiling and running a Java program.”)

After some pleasant chirping sounds from your hard drive, JCreator’s bottom pane displays a Process completed message. (See Figure 2-10.)

7. Choose Build ➪ Execute Project from the main menu.

When you choose Execute Project, the computer runs the project’s code. (That is, the computer runs a Java program that I wrote.) As part of the run, the message How much are you borrowing? appears in JCreator’s General Output pane. (Refer to Figure 2-8.)

8. Click anywhere inside JCreator’s General Output pane, and then type a number, like 100000.00, and press Enter.

When you type a number in Step 8, don’t include your country’s currency symbol and don’t use a grouping separator. (U.S. residents, don’t type a dollar sign and don’t use commas.) Things like $100000.00 or 100,000.00 cause the program to crash. You see a NumberFormatException message in the General Output pane.
After you press Enter, the Java program displays another message (What's the interest rate?) in JCreator’s General Output pane.

9. In response to the interest rate question, type a number, like 5.25, and press Enter.

After you press Enter, the Java program displays another message (How many years . . . ?) in JCreator’s General Output pane.

10. Type a number, like 30, and press Enter.

In response to the numbers that you’ve typed, the Java program displays a monthly payment amount. Again, refer to Figure 2-8. (Disclaimer: Your local mortgage company will charge you much more than the amount that my Java program calculates.)

When you type a number in Step 10, don’t include a decimal point. Things like 30.0 cause the program to crash. You see a NumberFormatException message in the General Output pane.

Occasionally you decide in the middle of a program’s run that you’ve made a mistake of some kind. You want to stop the program’s run dead in its tracks. To do this, choose Tools ➪ Stop Tool from the main menu.

Running a GUI on its own

In the previous section, you go through all the steps for compiling and running a text-based Java program. In this section, you go through the same steps for a GUI. The term GUI stands for Graphical User Interface. It’s the term used for a program that displays windows, buttons, and other nice-looking stuff. GUI programs are good because, unlike text-based programs, they don’t look like they’re running on your grandparents’ computers.

If you installed JCreator from this book’s CD-ROM, you can find a GUI version of the mortgage-calculating program in a project named Program0202. To run the program, just follow these instructions:

1. If you haven’t already done so, follow Steps 1 to 4 from the section entitled “Running a text-based program.”

When you finish with these steps, the Chapter02 workspace is open. JCreator remembers which workspace is open from one launch to another. So, if you ran the text-based program and then closed JCreator, you can just launch JCreator and skip the steps for opening the Chapter02 workspace (Steps 3 and 4 in the text-based program section).
2. In the File View’s tree, right-click the branch labeled Program0202. In the resulting context menu, choose Sets as Active Project. This makes Program0202 the active project.

3. Follow Steps 6 and 7 in the “Running a text-based program” section. This compiles and runs the Program0202 project’s code. The code displays a window like the one shown in Figure 2-11. In the window, you can experiment and type your own values for the principal, the interest rate, and the number of years of the loan. Whenever you change a value, the program responds instantly by updating the value in the Payment field.

Running a GUI on a Web page (a Java applet)

Java’s big splash onto the scene came in the mid-1990s. The people at Sun Microsystems had managed to work Java programs into Web pages, and the results were dazzling. The infusion of Java into the Web was powerful, efficient, portable, and secure. The trick was to create a part of a program, called an applet, and to display the applet inside a rectangle on the Web page.

These days, applets are passé. Real Java programmers roll their eyes when they hear the word applet. There are three reasons for this:

✔ Since the mid-1990s, better technologies have emerged for putting eye-catching content onto Web pages.

✔ Microsoft, the makers of the world’s most powerful Web browser, refused to give their browser the most up-to-date Java tools.

✔ For Java programmers, the real money isn’t in creating glittery Web pages. The real money is in business applications with J2EE.

For more information on J2EE, see Chapter 3.
Compiling and running a Java program

What does it mean for JCreator to “compile your project?” A compiler is a tool that translates code from one form to another. For instance, in my Program0201 project directory, I have a file named MortgageText.java. If you look inside the MortgageText.java file, you see code like this:

```java
import java.io.*;
import java.text.NumberFormat;
public class MortgageText {
    public static void main(String args[]) throws IOException
```

Although this code isn’t easy reading, it certainly uses letters and other characters that English-speaking people can understand. This file, MortgageText.java, is called Java source code. It’s the kind of code that you find out how to write by reading this book. It’s the code that you have before you’ve done any compiling — before you choose Build ➪ Compile Project from JCreator’s main menu.

When you choose Build ➪ Compile Project, the computer takes your source code and translates it into something called bytecode. The newly created bytecode file is automatically given a name like MortgageText.class. (You can open My Computer and look for the new .class file in your Program0201 directory.) Unlike the original .java file, the new .class file has no recognizable characters in it and isn’t suitable for human consumption. Instead, the .class file is streamlined so that the computer can carry out your program’s commands quickly and easily.

In the way that it compiles code, Java represents a strict departure from most other programming languages. When you compile a program in another language (COBOL or C++, for instance), you create a file that can be run on only one operating system. For example, if you compile a C++ program on a Windows computer and then move the translated file to a Mac, the Mac treats the translated file as pure garbage. The Mac can’t interpret any of the instructions in the translated file. This is bad for many reasons. One of the most striking reasons is that you can’t send this kind of code over the World Wide Web and expect anyone with a different kind of computer to be able to run the code.

But with Java, you can take a bytecode file that you created with a Windows computer, copy the bytecode to who-knows-what kind of computer, and then run the bytecode with no trouble at all. That’s one of the many reasons why Java has become popular so quickly. This outstanding feature, the ability to run code on many different kinds of computers, is called portability.

After compiling your Java project, choose Build ➪ Execute from the main menu. At this point, I normally say that your computer starts running a Java program. But to be really picky, your computer never actually “runs a Java program.” Instead, your computer runs something called the Java Virtual Machine (JVM). The use of a virtual machine is another way in which Java is different from other computer programming languages.

The Java Virtual Machine is a piece of software. Think of the JVM as a proxy, an errand boy, a go-between. The JVM serves as an interpreter between Java’s run-anywhere bytecode and your computer’s own system. As it runs, the JVM walks your computer through the execution of bytecode instructions. The JVM examines your bytecode, bit by bit, and carries out the instructions described in the bytecode. The JVM interprets bytecode for your Windows system, your Mac, your Linux box, or whatever kind of computer you’re using. That’s a good thing. It’s what makes Java programs more portable than any other language’s programs.
Passé or not, some people still want to create applets. So in this section, you run a simple Java applet. Just follow these steps:

1. **If you haven’t already done so, follow Steps 1 to 4 from the section entitled “Running a text-based program.”**

   When you finish with these steps, the Chapter02 workspace is open.

2. **In the File View’s tree, right-click the branch labeled Program0203. In the resulting context menu, choose Sets as Active Project.**

   This makes Program0203 the active project.

3. **Follow Steps 6 and 7 in the “Running a text-based program” section.**

   This compiles and runs the Program0202 project’s code. You see a new Web page containing a mortgage applet in the Web browser window. (See Figure 2-12.)

   ![Figure 2-12: The mortgage applet runs in your browser window.](image)

If you follow the steps in this section, and you don’t see the mortgage applet running in your Web browser, you can do a few things:

- ![Check your Web browser’s settings to make sure that the display of Java applets is enabled.](image)
- ![Make sure that you installed the Java plug-in.](image)
  
  See Step 5 of the section entitled “Installing Java on your computer.”

- ![Close any browser windows that you have open. Then return to JCreator and choose Build➪Execute Project again.](image)
  
  Sometimes this helps.

- ![Skip the whole applet business and move on to Chapter 3.](image)
  
  Hardly anyone uses Java applets these days anyway.
Running an applet

In this chapter, you can find a sidebar entitled “Compiling and running a Java program.” The sidebar describes the execution of a Java project. To execute a project, your computer runs a Java Virtual Machine (JVM), and this JVM carries a Java program’s instructions. That’s how it works for a project that doesn’t involve applets. But when your project involves an applet, the story is a bit different.

If you’ve worked with Web pages, you may be familiar with something called HTML — the Hypertext Markup Language. It’s the universal language for the World Wide Web. Almost every Web page starts with an HTML file. That’s why, when you expand Program0203 in JCreator’s File View pane, you see something named MyWebPage.html.

When JCreator executes the Program0203 project, it finds this MyWebPage.html file, and opens this file with Microsoft Internet Explorer. At this point, Internet Explorer takes on the full burden of running your code. Internet Explorer acts on the commands (the tags) in the MyWebPage.html file. In particular, Internet Explorer finds the following tag inside the MyWebPage.html file:

```html
<applet code="MortgageApplet"
       width=300
       height=200></applet>
```

This tag instructs Internet Explorer to look for the Java program named MortgageApplet. When it finds the program, Internet Explorer displays the applet (the text fields, the words Principal, Rate, Payment, and other stuff) in the browser window.

So that’s what JCreator does when you want an applet to be executed. JCreator doesn’t run the JVM directly. Instead, JCreator tells Internet Explorer to visit an HTML document. Then Internet Explorer runs the JVM and displays the applet on a Web page. Have you read about all the lawsuits between Microsoft and Sun Microsystems? At the heart of these lawsuits is the use of an outdated JVM in the Internet Explorer browser.

By the way, if JCreator doesn’t find Internet Explorer on your system, then JCreator opens the file with Sun’s appletviewer. The appletviewer is a small browser that’s designed specifically for viewing Java applets. The appletviewer displays nothing but applets (no hyperlinks, no images, no text other than the applet’s text) so you can’t use appletviewer to preview a complete Web page.
Chapter 3

Using the Basic Building Blocks

In This Chapter

► Speaking the Java language: the API and the Language Specification
► Understanding the parts of a simple program
► Documenting your code
► Editing and running a Java program

“All great ideas are simple.”

—Leo Tolstoy

The quotation applies to all kinds of things — things like life, love, and computer programming. That’s why this chapter takes a multilayered approach. In this chapter, you get your first blast of details about Java programming. But in discovering details, you see the simplicities.

Speaking the Java Language

If you try to picture in your mind the whole English language, what do you see? Maybe you see words, words, words. (That’s what Hamlet saw.) Looking at the language under a microscope, you see one word after another. The bunch-of-words image is fine, but if you step back a bit, you may see two other things:

✔ The language’s grammar
✔ Thousands of expressions, sayings, idioms, and historical names

The first category (the grammar) includes rules like, “The verb agrees with the noun in number and person.” The second category (expressions, sayings,
and stuff) includes knowledge like, “Julius Caesar was a famous Roman emperor, so don’t name your son Julius Caesar, unless you want him to get beat up every day after school.”

The Java programming language has all the aspects of a spoken language like English. Java has words, grammar, commonly used names, stylistic idioms, and other such things.

The grammar and the common names

The people at Sun Microsystems who created Java thought of Java as coming in two parts. Just as English has its grammar and commonly used names, the Java programming language has its specification (its grammar) and its Application Programming Interface (its commonly used names). Whenever I write Java programs, I keep two important pieces of documentation — one for each part of the language — on my desk:

✔ The Java Language Specification: This includes rules like, “Always put an open parenthesis after the word for” and “Use an asterisk to multiply two numbers.”

✔ The Application Programming Interface: Java’s Application Programming Interface (API) contains thousands of tools that were added to Java after the language’s grammar was defined. These tools range from the commonplace to the exotic. For instance, the tools include a routine named pow that can raise 5 to the 10th power for you. A more razzle-dazzle tool (named JFrame) displays a window on your computer’s screen. Other tools listen for the user’s button clicks, query databases, and do all kinds of useful things.

You can download the Language Specification, the API documents, and all the other Java documentation (or view the documents online) by poking around at java.sun.com/j2se/1.5.0/download.jsp and at java.sun.com/j2se/1.5.0/docs/index.html. But watch out! These Web pages are moving targets. By the time you read this book, the links in this paragraph will probably be out of date. The safest thing to do is to start at java.sun.com/j2se, and then look for links to things like “version 5.0” and “documentation.”

The first part of Java, the Language Specification, is relatively small. That doesn’t mean you won’t take plenty of time finding out how to use the rules in the Language Specification. Other programming languages, however, have double, triple, or ten times the number of rules.

The second part of Java — the API — can be intimidating because it’s so large. The API contains at least 3,000 tools and keeps growing with each new Java language release. Pretty scary, eh? Well, the good news is that you don’t have to memorize anything in the API. Nothing. None of it. You can look up
the stuff you need to use in the documentation and ignore the stuff you don’t need. What you use often, you’ll remember. What you don’t use often, you’ll forget (like any other programmer).

For information on how to find things in Java’s API documentation, see the section entitled “Finding javadoc pages,” later in this chapter.

No one knows all there is to know about the Java API. If you’re a Java programmer who frequently writes programs that open new windows, you know how to use the API Frame class. If you seldom write programs that open windows, the first few times you need to create a window, you can look up the Frame class in the API documentation. My guess is that if you took a typical Java programmer and kept that programmer from looking up anything in the API documentation, the programmer would be able to use less than 2 percent of all the tools in the Java API.

Sure, you may love the *For Dummies* style. But unfortunately, Java’s official API documentation isn’t written that way. The API documentation is both concise and precise. For some help deciphering the API documentation’s language and style, see this book’s Web site.

In a way, nothing about the Java API is special. Whenever you write a Java program — even the smallest, simplest Java program — you create a class that’s on par with any of the classes defined in the official Java API. The API is just a set of classes and other tools that were created by ordinary programmers who happen to participate in the official JCP — the *Java Community Process*. Unlike the tools that you create yourself, the tools in the API are distributed with every version of Java. (I’m assuming that you, the reader, are not a participant in the Java Community Process. But then, with a fine book like *Java 2 For Dummies, 2nd Edition*, one never knows.)

If you’re interested in the JCP’s activities, visit www.jcp.org.

The folks at the JCP don’t keep the Java programs in the official Java API a secret. If you want, you can look at all these programs. When you install Java on your computer, the installation puts a file named src.zip on your hard drive. You can open src.zip with your favorite unzipping program. There, before your eyes, is all the Java API code.

**The words in a Java program**

A hard-core Javateer will say that the Java programming language has two different kinds of words: keywords and identifiers. This is true. But the bare truth, without any other explanation, is sometimes misleading. So I recommend dressing up the truth a bit and thinking in terms of three kinds of words: keywords, identifiers that ordinary programmers like you and me create, and identifiers from the API.
The differences among these three kinds of words are similar to the differences among words in the English language. In the sentence “Sam is a person,” the word person is like a Java keyword. No matter who uses the word person, the word always means roughly the same thing. (Sure, you can think of bizarre exceptions in English usage, but please don’t.)
The word *Sam* is like a Java identifier because Sam is a name for a particular person. Words like *Sam, Dinswald,* and *McGillmaroo* don’t come prepacked with meaning in the English language. These words apply to different people depending on the context and become names when parents pick one for their newborn kid.

Now consider the sentence “Julius Caesar is a person.” If you utter this sentence, you’re probably talking about the fellow who ruled Rome until the Ides of March. Although the name *Julius Caesar* isn’t hard-wired into the English language, almost everyone uses the name to refer to the same person. If English were a programming language, the name *Julius Caesar* would be an API identifier.

So here’s how I, in my own mind, divide the words in a Java program into categories:

**Keywords:** A *keyword* is a word that has its own special meaning in the Java programming language, and that meaning doesn’t change from one program to another. Examples of keywords in Java include *if, else,* and *do.* The Cheat Sheet in the front of this book has a complete list of Java keywords.

The JCP committee members, who have the final say on what constitutes a Java program, have chosen all of Java’s keywords. Thinking about the two parts of Java, which I discuss in “The grammar and the common names” section earlier in this chapter, the Java keywords belong solidly to the Language Specification.

**Identifiers:** An *identifier* is a name for something. The identifier’s meaning can change from one program to another, but some identifiers’ meanings tend to change more than others.

- **Identifiers created by you and me:** As a Java programmer (yes, even as a novice Java programmer), you create new names for classes and other things that you describe in your programs. Of course, you may name something *Prime,* and the guy writing code two cubicles down the hall can name something *else Prime.* That’s okay because Java doesn’t have a predetermined meaning for the word *Prime.* In your program, you can make *Prime* stand for the Federal Reserve’s prime rate. And the guy down the hall can make *Prime* stand for the “bread, roll, preserves, and prime rib.” A conflict doesn’t arise, because you and your co-worker are writing two different Java programs.

- **Identifiers from the API:** The JCP members have created names for many things and thrown at least 3,000 of these names into the Java API. The API comes with each version of Java, so these names are available to anyone who writes a Java program. Examples of such names are *String, Integer, JWindow, JButton, JTextField,* and *File.*
Strictly speaking, the meanings of the identifiers in the Java API are not cast in stone. Although you can make up your own meanings for the words like Button or Window, this isn't a good idea. If you did, you would confuse the dickens out of other programmers, who are used to the standard API meanings for these familiar identifier names. But even worse, when your code assigns a new meaning to an identifier like Button, you lose any computational power that was created for the identifier in the API code. The programmers at Sun Microsystems did all the work writing Java code to handle buttons. If you assign your own meaning to the word Button, you're turning your back on all the progress made in creating the API.

**Checking Out Java Code for the First Time**

The first time you look at somebody else's Java program, you tend to feel a bit queasy. The realization that you don't understand something (or many things) in the code can make you nervous. I've written hundreds (maybe thousands) of Java programs, but I still feel insecure when I start reading someone else's code.

The truth is that finding out about a Java program is a bootstrapping experience. First you gawk in awe of the program. Then you run the program to see what it does. Then you stare at the program for a while or read someone's explanation of the program and its parts. Then you gawk a little more and run the program again. Eventually, you come to terms with the program. (Don't believe the wise guys who say they never go through these steps. Even the experienced programmers approach a new project slowly and carefully.)

In Listing 3-1, you get a blast of Java code. (Like all novice programmers, you're expected to gawk humbly at the code.) Hidden in the code, I've placed some important ideas, which I explain in detail in the next section. These ideas include the use of classes, methods, and Java statements.

**Listing 3-1: The Simplest Java Program**

```java
class Displayer {
    public static void main(String args[]) {
        System.out.println("You'll love Java!");
    }
}
```

To see the code of Listing 3-1 in the JCreator work area, follow these steps:
1. Open the Chapter03 workspace, and within that workspace, make Listing0301 the active project. (See Chapter 2 for details.)

In the File View pane’s tree, the name Listing0301 is set in boldface. Under Listing0301, you see a branch labeled Display.java.

2. Double-click the Display.java branch in the File View pane’s tree.

JCreator’s Editor pane appears on the right side of the work area. The Editor pane contains the code in Listing 3-1.

After following the first step above, you can run the code in Listing 3-1 by choosing Build ‹ Compile Project, and then choosing Build ‹ Execute Project. (See Chapter 2 for details.)

When you run the program from Listing 3-1, the computer displays You’ll love Java! (See Figure 3-1.) Now, I admit that writing and running a Java program is a lot of work just to get You’ll love Java! to appear on somebody’s computer screen, but every endeavor has to start somewhere.

In the following section, you do more than just run the program and admire the program’s output. After you read the following section, you actually understand what makes the program in Listing 3-1 work.

---

**Figure 3-1:** Running the program in Listing 3-1.

---

**Understanding the Simple Java Program**

This section presents, explains, analyzes, dissects, and otherwise demystifies the Java program shown previously in Listing 3-1.

---

**The Java class**

Because Java is an object-oriented programming language, your primary goal is to describe classes and objects. (If you’re not convinced about this, read the sections on object-oriented programming in Chapter 1.)

On those special days when I’m feeling sentimental, I tell people that Java is more pure in its object-orientation than most other so-called object-oriented languages. I say this because, in Java, you can’t do anything until you’ve created a class of some kind. It’s like being on Jeopardy!, hearing Alex Trebec
say, “Let’s go to a commercial;” and then interrupting him by saying, “I’m sorry, Alex. You can’t issue an instruction without putting your instruction inside a class.”

In Java, the entire program is a class. I wrote the program, so I get to make up a name for my new class. I chose the name Displayer, because the program displays a line of text on the computer screen. That’s why the code in Listing 3-1 starts with class Displayer. (See Figure 3-2.)

The first word in Listing 3-1, the word class, is a Java keyword. (See the section “The words in a Java program,” earlier in this chapter.) No matter who writes a Java program, the word class is always used the same way. On the other hand, the word Displayer in Listing 3-1 is an identifier. I made up the word Displayer while I was writing this chapter. The word Displayer is the name of a particular class — the class that I’m creating by writing this program.

The Java programming language is case-sensitive. This means that if you change a lowercase letter in a word to an uppercase letter, you change the word’s meaning. Changing case can make the entire word go from being meaningful to being meaningless. In the first line of Listing 3-1, you can’t replace class with Class. If you do, the whole program stops working.

**The Java method**

You’re working as an auto mechanic in an upscale garage. Your boss, who’s always in a hurry and has a habit of running words together, says, “FixTheAlternator on that junkyOldFord.” Mentally, you run through a list of tasks. “Drive the car into the bay, lift the hood, get a wrench, loosen the alternator belt,” and so on. Three things are going on here:
You have a name for the thing you’re supposed to do. The name is FixTheAlternator.

In your mind, you have a list of tasks associated with the name FixTheAlternator. The list includes “Drive the car into the bay, lift the hood, get a wrench, loosen the alternator belt,” and so on.

You have a grumpy boss who’s telling you to do all this work. Your boss gets you working by saying, “FixTheAlternator.” In other words, your boss gets you working by saying the name of the thing you’re supposed to do.

In this scenario, using the word method wouldn’t be a big stretch. You have a method for doing something with an alternator. Your boss calls that method into action, and you respond by doing all the things in the list of instructions that you’ve associated with the method.

If you believe all that (and I hope you do), then you’re ready to read about Java methods. In Java, a method is a list of things to do. Every method has a name, and you tell the computer to do the things in the list by using the method’s name in your program.

I’ve never written a program to get a robot to fix an alternator. But, if I did, the program may include a FixTheAlternator method. The list of instructions in my FixTheAlternator method would look something like the text in Listing 3-2.

### Listing 3-2: A Method Declaration

```java
void FixTheAlternator() {
    DriveInto(car, bay);
    Lift(hood);
    Get(wrench);
    Loosen(alternatorBelt);
    ...
}
```

Somewhere else in my Java code (somewhere outside of Listing 3-2), I need an instruction to call my FixTheAlternator method into action. The instruction to call the FixTheAlternator method into action may look like the line in Listing 3-3.

### Listing 3-3: A Method Call

```java
FixTheAlternator(junkyOldFord);
```

Don’t scrutinize Listings 3-2 and 3-3 too carefully. All the code in Listings 3-2 and 3-3 is fake! I made up this code so that it looks a lot like real Java code, but it’s not real. What’s more important, the code in Listings 3-2 and 3-3 isn’t meant to illustrate all the rules about Java. So, if you have a grain of salt handy, take it with Listings 3-2 and 3-3.
Now that you have a basic understanding of what a method is and how it works, you can dig a little deeper into some useful terminology:

- If I’m being lazy, I refer to the code in Listing 3-2 as a method. If I’m not being lazy, I refer to this code as a method declaration.
- The method declaration in Listing 3-2 has two parts. The first line (the part with FixTheAlternator in it, up to but not including the open curly brace) is called a method header. The rest of Listing 3-3 (the part surrounded by curly braces) is a method body.
- The term method declaration distinguishes the list of instructions in Listing 3-2 from the instruction in Listing 3-3, which is known as a method call.

A method’s declaration tells the computer what happens if you call the method into action. A method call (a separate piece of code) tells the computer to actually call the method into action. A method’s declaration and the method’s call tend to be in different parts of the Java program.

### The main method in a program

Figure 3-3 has a copy of the code from Listing 3-1. The bulk of the code contains the declaration of a method named main. (Just look for the word main in the code’s method header.) For now, don’t worry about the other words in the method header — the words public, static, void, String, and args. I explain these words in the next several chapters.
Like any Java method, the `main` method is a recipe.

*How to make biscuits:*
- Heat the oven.
- Roll the dough.
- Bake the rolled dough.

or

*How to follow the main instructions for a Displayer:*
- Print "You'll love Java!" on the screen.

The word `main` plays a special role in Java. In particular, you never write code that explicitly calls a `main` method into action. The word `main` is the name of the method that is called into action automatically when the program begins running.

So look back at Figure 3-1. From within JCreator you choose Build ➪ Execute Project to run the Displayer program. When the Displayer program runs, the computer automatically finds the program's `main` method and executes any instructions inside the method's body. In the Displayer program, the `main` method's body has only one instruction. That instruction tells the computer to print *You'll love Java!* on the screen. So in Figure 3-1, *You'll love Java!* appears in JCreator's General Output pane.

None of the instructions in a method are executed until the method is called into action. But, if you give a method the name `main`, that method is called into action automatically.

Almost every computer programming language has something akin to Java’s methods. If you’ve worked with other languages, you may remember things like subprograms, procedures, functions, subroutines, subprocedures, or PERFORM statements. Whatever you call it in your favorite programming language, a method is a bunch of instructions collected together and given a new name.

**How you finally tell the computer to do something**

Buried deep in the heart of Listing 3-1 is the single line that actually issues a direct instruction to the computer. The line, which is highlighted in Figure 3-4, tells the computer to display *You'll love Java!* This line is known as a statement. In Java, a *statement* is a direct instruction that tells the computer to do something (for example, display this text, put 7 in that memory location, make a window appear).
Of course, Java has different kinds of statements. A method call, which I introduce in “The Java method,” earlier in this chapter, is one of the many kinds of Java statements. Listing 3-3 shows you what a method call looks like, and Figure 3-4 also contains a method call that looks like this:

```
System.out.println("You'll love Java!");
```

When the computer starts executing this statement, the computer calls a method named `System.out.println` into action. (Yes, in Java, a name can have dots in it. The dots mean something.)

To find out the meaning behind the dots in Java names, see Chapter 7.

Figure 3-5 illustrates the `System.out.println` situation. Actually, two methods play active roles in the running of the `Displayer` program. Here’s how they work:

- **There’s a declaration for a main method.** I wrote the main method myself. This main method is called automatically whenever I start running the `Displayer` program.

- **There’s a call to the `System.out.println` method.** The method call for the `System.out.println` method is the only statement in the body of the main method. In other words, calling the `System.out.println` method is the only thing on the main method’s to-do list.

  The declaration for the `System.out.println` method is buried inside the official Java API. For a refresher on the Java API, see the sections, “The grammar and the common names” and “The words in a Java program,” earlier in this chapter.

When I say things like “`System.out.println` is buried inside the API,” I’m not doing justice to the API. True, you can ignore all the nitty-gritty Java code inside the API. All you need to remember is that `System.out.println` is defined somewhere inside that code. But I’m not being fair when I make the API code sound like something magical. The API is just another bunch of Java code. The statements in the API that tell the computer what it means to carry out a call to `System.out.println` look a lot like the Java code in Listing 3-1.
In Java, each statement (like the boxed line in Figure 3-4) ends with a semicolon. Other lines in Figure 3-4 don’t end with semicolons, because the other lines in Figure 3-4 aren’t statements. For instance, the method header (the line with the word `main` in it) doesn’t directly tell the computer to do anything. The method header announces, “Just in case you ever want to do `main`, the next few lines of code tell you how you’ll do it.”

Every complete Java statement ends with a semicolon.

**Curly braces**

Long ago, or maybe not so long ago, your schoolteachers told you how useful outlines are. With an outline, you can organize thoughts and ideas, help people see forests instead of trees, and generally show that you’re a member of the Tidy Persons Club. Well, a Java program is like an outline. The program in Listing 3-1 starts with a big header line that says, “Here comes a class named `Displayer`.” After that first big header is a subheader that announces, “Here comes a method named `main`.”
Now, if a Java program is like an outline, why doesn’t a program look like an outline? What takes the place of the Roman numerals, capital letters, and other things? The answer is twofold:

- In a Java program, curly braces enclose meaningful units of code.
- You, the programmer, can (and should) indent lines so that other programmers can see the outline form of your code at a glance.

In an outline, everything is subordinate to the item in Roman numeral I. In a Java program, everything is subordinate to the top line — the line with the word `class` in it. To indicate that everything else in the code is subordinate to this class line, you use curly braces. Everything else in the code goes inside these curly braces. (See Listing 3-4.)

**Listing 3-4: Curly Braces for a Java Class**

```java
class Displayer {
    public static void main(String args[]) {
        System.out.println("You'll love Java!");
    }
}
```

In an outline, some stuff is subordinate to a capital letter A item. In a Java program, some lines are subordinate to the method header. To indicate that something is subordinate to a method header, you use curly braces. (See Listing 3-5.)

**Listing 3-5: Curly Braces for a Java Method**

```java
class Displayer {
    public static void main(String args[]) {
        System.out.println("You'll love Java!");
    }
}
```

In an outline, some items are at the bottom of the food chain. In the `Displayer` class, the corresponding line is the line that begins with `System.out.println`. Accordingly, this `System.out.println` line goes inside all the other curly braces and is indented more than anything else.

Never lose sight of the fact that a Java program is, first and foremost, an outline.

If you put curly braces in the wrong places or omit curly braces where the braces should be, your program probably won’t work at all. If your program works, it’ll probably work incorrectly.
If you don’t indent lines of code in an informative manner, your program will still work correctly, but neither you nor any other programmer will be able to figure out what you were thinking when you wrote the code.

If you’re one of those visual thinkers, you could picture outlines of Java programs in your head. One friend of mine visualizes an actual numbered outline morphing into a Java program. (See Figure 3-6.) Another person, who shall remain nameless, uses more bizarre imagery. (See Figure 3-7.)
And Now, a Few Comments

People gather around campfires to hear the old legend about a programmer whose laziness got her into trouble. To maintain this programmer’s anonymity, I call her Jane Pro. Jane worked many months to create the holy grail of computing — a program that thinks on its own. If completed, this program could work independently, learning new things without human intervention. Day after day, night after night, she labored to give the program that spark of creative, independent thought.

One day, when she was almost finished with the project, she received a disturbing piece of paper mail from her health insurance company. No, the mail wasn’t about a serious illness. It was about a routine office visit. The insurance company’s claim form had a place for her date of birth, as if her date of birth had changed since the last time she sent in a claim. She had absent-mindedly scribbled 2004 as her year of birth, so the insurance company refused to pay the bill.

Jane dialed the insurance company’s phone number. Within twenty minutes she was talking to a live person. “I’m sorry,” said the live person. “To resolve this issue you must dial a different number.” Well, you can guess what happened next. “I’m sorry. The other operator gave you the wrong number.” And then “I’m sorry. You must call back the original phone number.”

Five months later, Jane’s ear ached, but after 800 hours on the phone she had finally gotten a tentative promise that the insurance company would eventually reprocess the claim. Elated as she was, she was anxious to get back to her computer programming project. Could she remember what all those lines of code were supposed to be doing?

No, she couldn’t. She stared and stared at her own work and, like a dream that doesn’t make sense the next morning, the code was now completely meaningless to her. She had written a million lines of code and not one line was accompanied by an informative explanatory comment. She had left no clues to help her understand what she’d been thinking, so in frustration, she abandoned the whole project.

Adding comments to your code

Listing 3-6 has an enhanced version of this chapter’s sample program. In addition to all the keywords, identifiers, and punctuation, Listing 3-6 has text that’s meant for human beings to read.
A comment is a special section of text inside a program. It is text whose purpose is to help people understand the program. A comment is part of a good program’s documentation.

The Java programming language has three different kinds of comments:

- **Traditional comments**: The first five lines of Listing 3-6 form one traditional comment. The comment begins with /* and ends with */. Everything between the opening */ and the closing */ is for human eyes only. No information about "Java 2 For Dummies" or Wiley Publishing, Inc. is translated by the compiler.

To read about compilers, see Chapter 2.

The second, third, and fourth lines in Listing 3-6 have extra asterisks (*). I call them extra because these asterisks aren’t required when you create a comment. They just make the comment look pretty. I include them in Listing 3-6 because, for some reason that I don’t entirely understand, most Java programmers add these extra asterisks.

- **End-of-line comments**: The text // in Listing 3-6 is an end-of-line comment. An end-of-line comment starts with two slashes, and goes to the end of a line of type. Once again, no text inside the end-of-line comment gets translated by the compiler.
Javadoc comments: A javadoc comment begins with a slash and two asterisks (**). Listing 3-6 has two javadoc comments — one with text The Displayer class . . . and another with text Execution of the program . . . .

A javadoc comment is a special kind of traditional comment. A javadoc comment is meant to be read by people who never even look at the Java code. But that doesn’t make sense. How can you see the javadoc comments in Listing 3-6 if you never look at Listing 3-6?

Well, a certain program called javadoc (what else?) can find all the javadoc comments in Listing 3-6 and turn these comments into a nice-looking Web page. The page is shown in Figure 3-8.

Figure 3-8: The javadoc page generated from the code in Listing 3-6.
Javadoc comments are great. Here are several great things about them:

- The only person who has to look at a piece of Java code is the programmer who writes the code. Other people who use the code can find out what the code does by viewing the automatically generated Web page.
- Because other people don’t look at the Java code, other people don’t make changes to the Java code. (In other words, other people don’t introduce errors into the existing Java code.)
- Because other people don’t look at the Java code, other people don’t have to decipher the inner workings of the Java code. All these people need to know about the code is what they read in the code’s Web page.
- The programmer doesn’t create two separate things — some Java code over here and some documentation about the code over there. Instead, the programmer creates one piece of Java code and embeds the documentation (in the form of javadoc comments) right inside the code.
- Best of all, the generation of Web pages from javadoc comments is done automatically. So everyone’s documentation has the same format. No matter whose Java code you use, you find out about that code by reading a page like the one in Figure 3-8. That’s good because the format in Figure 3-8 is familiar to anyone who uses Java.

You can generate your own Web pages from the javadoc comments that you put in your code. To discover how, visit this book’s Web site.

What’s Barry’s excuse?

For years, I’ve been telling my students to put comments in their code, and for years I’ve been creating sample code (like the code in Listing 3-1) with no comments in it. Why?

Three little words: “Know your audience.” When you write complicated, real-life code, your audience is other programmers, information technology managers, and people who need help deciphering what you’ve done. When I write simple samples of code for this book, my audience is you — the novice Java programmer. Instead of reading my comments, your best strategy is to stare at my Java statements — the statements that Java’s compiler deciphers. That’s why I put so few comments in this book’s listings.

Besides, I’m a little lazy.

Finding javadoc pages

In Chapter 2, I encourage you to download a copy of the official Java API documentation. This API documentation is a huge collection of Web pages
created automatically from javadoc comments. To access this documentation, do the following:

1. **Follow Steps 1 and 2 in the step list that comes immediately after Listing 3-1 in this chapter.**
   
The code of Listing 3-1 appears in JCreator’s Editor pane.

2. **In the Editor pane, right-click the word System. In the resulting context menu, choose Show JDK Help.**
   
The javadoc page for System appears in JCreator’s Editor pane. To see more of this page, use the pane’s scrollbar. The stuff on this page may not make much sense to you now, but as you read more of this book, things become clearer.
   
   For tips on reading and understanding Java’s API documentation, see this book’s Web site.

3. **Click the Displayer.java tab at the top of the Editor pane.**
   
The code of Listing 3-1 appears once again.

4. **In the Editor pane, right-click the word println, and choose Show JDK Help from the context menu that appears.**
   
The documentation for the println method appears in the Editor pane.

---

**Using comments to experiment with your code**

You may hear programmers talk about commenting out certain parts of their code. When you’re writing a program and something’s not working correctly, it often helps to try removing some of the code. If nothing else, you find out what happens when that suspicious code is removed. Of course, you may not like what happens when the code is removed, so you don’t want to delete the code completely. Instead, you turn your ordinary Java statements into comments. For instance, you turn the statement

```java
System.out.println("I love Java!");
```

into the comment

```java
// System.out.println("I love Java!");
```

This keeps the Java compiler from seeing the code while you try to figure out what’s wrong with your program.
Traditional comments aren’t very useful for commenting out code. The big problem is that you can’t put one traditional comment inside of another. For instance, suppose you want to comment out the following statements:

```java
System.out.println("Parents.");
System.out.println("pick your");
/*
 * Intentionally displays on four separate lines
 */
System.out.println("battles");
System.out.println("carefully!");
```

If you try to turn this code into one traditional comment, you get the following mess:

```java
/*
 System.out.println("Parents.");
 System.out.println("pick your");
 /*
 * Intentionally displays on four separate lines
 */
 System.out.println("battles");
 System.out.println("carefully!");
 */
```

The first */ (after Intentionally displays) ends the traditional comment prematurely. Then the battles and carefully statements aren’t commented out, and the last */ chokes the compiler.

So the best way to comment out code is to use end-of-line comments. But typing two slashes for each of ten lines can be tedious. Fortunately, JCreator has a good shortcut. Here’s how it works:

1. Select the lines that you want to comment out.
2. From the JCreator menu bar, choose Edit ➪ Format ➪ Increase Comment Indent.

When you do this, each selected line becomes an end-of-line comment. End-of-line comments can contain traditional comments (and end-of-line comments can contain other end-of-line comments) so you can comment out the Parents, pick your battles carefully! code with no unwanted side effects. If you decide later to uncomment the code, that’s easy, too:

1. Select the lines that you no longer want to be commented out.
2. From the JCreator menu bar, choose Edit ➪ Format ➪ Decrease Comment Indent.
Typing Your Own Code

Chapter 2 is about running someone else’s Java code (code that you download from this book’s Web site). But eventually, you’ll write code on your own. This section shows you how to create code with the JCreator development environment.

The version of JCreator on this book’s CD-ROM has a specially customized MyProjects directory. The MyProjects directory contains several ready-made workspaces. One of these workspaces (named MyWorkspace) has no projects in it. Here’s how you create a project in MyWorkspace:

1. **Launch JCreator.**

2. **From JCreator’s menu bar, choose File ➪ Open Workspace.**
   
   An Open dialog box appears.

3. **In the Open dialog box, select MyWorkspace.jcw (or simply MyWorkspace). Then click Open.**
   
   Clicking Open may coax out a message box asking whether you want to “Save the workspace modifications?” If so, click Yes. Clicking Open may coax out another box asking if you want to “. . . close all document Windows?” If so, click Yes.

   In MyWorkspace.jcw, the extension .jcw stands for “JCreator workspace.”

   After clicking Open, you see MyWorkspace in JCreator’s File View pane. The next step is to create a new project within MyWorkspace.

4. **In the File View pane, right-click MyWorkspace. Then choose Add new Project from the context menu that appears, as shown in Figure 3-9.**
   
   JCreator’s Project Wizard opens. (See Figure 3-10.)

5. **In the wizard’s Project Template tab, select the Empty Project icon, and then click Next.**
   
   After clicking Next, you see the wizard’s Project Paths tab, as shown in Figure 3-11.

Figure 3-9: Getting JCreator to add a new project.
6. In the Name field, type **MyFirstProject**.

   You can add blank spaces, making the name My First Project, but I don’t recommend it.

7. Make sure that the Add to Current Workspace radio button is selected, and then click Finish.

   If you click Next instead of Finish, you see some other options that you don’t need right now. So to avoid any confusion, just click Finish.

   Clicking Finish brings you back to JCreator’s work area, with **MyFirstProject** set in bold. The bold typeface means that **MyFirstProject** is the active project. The next step is to create a new Java source code file.
8. In the File View pane, right-click MyFirstProject. Then choose Add➪New Class from the context menu that appears, as shown in Figure 3-12.

JCreator’s Class Wizard opens. (See Figure 3-13.)

Like every other windowed environment, JCreator provides many ways to accomplish the same task. Instead of right-clicking MyFirstProject, you can go to the menu bar and choose File➪New➪Class. But right-clicking a project has a small benefit. If you right-click the name of a project, the newly created class is without a doubt in that project. If you use the menu bar instead, the newly created class goes in whichever project happens to be the active project. So if your workspace contains many projects, you can accidentally put the new class into the wrong project.

9. In the Class Wizard’s Name field, type the name of your new class.

For this first project, I highly recommend the name Displayer. To be safe, use an uppercase letter D and lowercase letters for all the other characters. (See Figure 3-13.)
10. Skip everything in the Class Wizard except the Name field. (In other words, click Finish.)

Clicking Finish brings you back to JCreator’s work area. Now the Editor pane has a tab named Displayer.java. For your convenience, the Displayer.java tab already has a tiny bit of code in it. (See Figure 3-14.)

11. Type your new Java program.

Add your code to the code in JCreator’s Editor pane. For this first project, I recommend copying the code in Listing 3-1 exactly as you see it.

- Spell each word exactly the way I spell it in Listing 3-1.
- Capitalize each word exactly the way I do in Listing 3-1.
- Include all the punctuation symbols — the curly braces, the semicolon, everything.

12. From the menu bar, choose Build➪Compile Project.

If you typed everything correctly, you see the comforting Process completed message, with no error messages, at the bottom of JCreator’s work area. The text appears in JCreator’s Build Output pane, which now covers up the old General Output pane. (See Figure 3-15.)

When you choose Build➪Compile Project, JCreator compiles whichever project is currently active. Only one project at a time is active. So if your workspace contains several projects, make sure that the project you want to compile is currently the active project.
13. **Check for error messages at the bottom of JCreator’s work area.**

   If, in Step 11, you didn’t type the code exactly as it’s shown in Listing 3-1, you see some error messages in the Task List pane. (Like so many other things, the Task List pane appears at the bottom of JCreator’s work area.)

   Each error message refers to a specific place in your Java code. To jump the cursor to that place in the Editor pane, double-click the message in the Task List pane. Compare everything you see, character by character, with my code in Listing 3-1. Don’t miss a single detail, including spelling, punctuation, and uppercase versus lowercase.

14. **Make any changes or corrections to the code in the Editor pane. Then repeat Steps 12 and 13.**

   When at last you see the Process completed message with no error messages, you’re ready to run the program.

15. **From the menu bar choose Build➪Execute Project.**

   That does the trick. Your new Java program runs in JCreator’s General Output pane. If you’re running the code in Listing 3-1, you see the You’ll love Java! message in Figure 3-1. And believe me; messages like this are never wrong.
Part II

Writing Your Own Java Programs

The 5th Wave
By Rich Tennant

"Before I go on to explain more advanced procedures like the 'Zap Rowdy Students-who-Don't-Pay-Attention' function, we'll begin with some basics."
In this part . . .

In this part, you dig in and get dirty by writing some programs and finding out what Java really feels like. Some of the stuff in this part is specific to Java, but lots of the material is just plain old generic computer programming. Here you concentrate on details — details about data, logic, and program flow. After you've read this part and practiced some of the techniques, you can write all kinds of interesting Java programs.
Chapter 4

Making the Most of Variables and Their Values

In This Chapter
- Assigning values to things
- Making things store certain types of values
- Applying operators to get new values

The following conversation between Van Doren and Philbin never took place:

Charles: A sea squirt eats its brain, turning itself from an animal into a plant.

Regis: Is that your final answer, Charles?
Charles: Yes, it is.

Regis: How much money do you have in your account today, Charles?
Charles: I have fifty dollars and twenty-two cents in my checking account.

Regis: Well, you better call the IRS, because I’m putting another million dollars in your account. What do you think of that, Charles?
Charles: I owe it all to honesty, diligence, and hard work, Regis.

Some aspects of this dialogue can be represented in Java by a few lines of code.

Varying a Variable

No matter how you acquire your million dollars, you can use a variable to tally your wealth. The code is shown in Listing 4-1.
Listing 4-1: Using a Variable

```
amountInAccount = 50.22;
amountInAccount = amountInAccount + 1000000.00;
```

The code in Listing 4-1 makes use of the `amountInAccount` variable. A variable is a placeholder. You can stick a number like 50.22 into a variable. After you place a number in the variable, you can change your mind and put a different number into the variable. (That's what varies in a variable.) Of course, when you put a new number in a variable, the old number is no longer there. If you didn’t save the old number somewhere else, the old number is gone.

Figure 4-1 gives a before-and-after picture of the code in Listing 4-1. After the first statement in Listing 4-1 is executed, the variable `amountInAccount` has the number 50.22 in it. Then, after the second statement of Listing 4-1 is executed, the `amountInAccount` variable suddenly has 1000050.22 in it. When you think about a variable, picture a place in the computer’s memory where wires and transistors store 50.22, 1000050.22, or whatever. In the left side of Figure 4-1, imagine that the box with the number 50.22 in it is surrounded by millions of other such boxes.

Now you need some terminology. The thing stored in a variable is called a value. A variable’s value can change during the run of a program (when Regis gives you a million bucks, for instance). The value that’s stored in a variable isn’t necessarily a number. (You can, for instance, create a variable that always stores a letter.) The kind of value that’s stored in a variable is a variable’s type.

You can read more about types in the section “Understanding the Types of Values That Variables May Have,” later in this chapter.
A subtle, almost unnoticeable difference exists between a variable and a variable's name. Even in formal writing, I often use the word variable when I mean variable name. Strictly speaking, amountInAccount is a variable name, and all the memory storage associated with amountInAccount (including the type that amountInAccount has and whatever value amountInAccount currently represents) is the variable itself. If you think this distinction between variable and variable name is too subtle for you to worry about, join the club.

Every variable name is an identifier — a name that you can make up in your own code. In preparing Listing 4-1, I made up the name amountInAccount.

For more information on the kinds of names in a Java program, see Chapter 3.

Before the sun sets on Listing 4-1, you need to notice one more part of the listing. The listing has 50.22 and 1000000.00 in it. Anybody in his or her right mind would call these things numbers, but in a Java program it helps to call these things literals.

And what’s so literal about 50.22 and 1000000.00? Well, think about the variable amountInAccount in Listing 4-1. The variable amountInAccount stands for 50.22 some of the time, but it stands for 1000050.22 the rest of the time. You could sort of use the word number to talk about amountInAccount. But really, what amountInAccount stands for depends on the fashion of the moment. On the other hand, 50.22 literally stands for the value 50\%

A variable’s value changes; a literal’s value doesn’t.

**Assignment Statements**

Statements like the ones in Listing 4-1 are called assignment statements. In an assignment statement, you assign a value to something. In many cases, this something is a variable.

I recommend getting into the habit of reading assignment statements from right to left. For instance, the first line in Listing 4-1 says,

```
"Assign 50.22...
amountInAccount = 50.22;
...to the
amountInAccount
variable."
```
The second line in Listing 4-1 is just a bit more complicated. Reading the second line from right to left, you get

```
    amountInAccount = amountInAccount + 1000000.00;

...and make that number (1000050.22) be the new value of the amountInAccount variable.
```

In an assignment statement, the thing being assigned a value is always on the left side of the equal sign.

**Understanding the Types of Values That Variables May Have**

Have you seen the TV commercials that make you think you’re flying around among the circuits inside a computer? Pretty cool, eh? These commercials show 0s (zeros) and 1s sailing by because 0s and 1s are the only things that computers can really deal with. When you think a computer is storing the letter *J*, the computer is really storing 01001010. Everything inside the computer is a sequence of 0s and 1s. As every computer geek knows, a 0 or 1 is called a *bit*.

As it turns out, the sequence 01001010, which stands for the letter *J*, can also stand for the number 74. The same sequence can also stand for $1.0369608636003646 \times 10^{-43}$. In fact, if the bits are interpreted as screen pixels, the same sequence can be used to represent the dots shown in Figure 4-2. The meaning of 01001010 depends on the way the software interprets this sequence of 0s and 1s.
So how do you tell the computer what 01001010 stands for? The answer is in the concept of type. The type of a variable is the range of values that the variable is permitted to store.

I copied the lines from Listing 4-1 and put them into a complete Java program. The program is in Listing 4-2. When I run the program in Listing 4-2, I get the output shown in Figure 4-3.

Listing 4-2: A Program Uses amountInAccount

```java
import static java.lang.System.out;

class Millionaire {
    public static void main(String args[]) {
        double amountInAccount;
        amountInAccount = 50.22;
        amountInAccount = amountInAccount + 1000000.00;
        out.print("You have ");
        out.print(amountInAccount);
        out.println(" in your account.");
    }
}
```

In Listing 4-2, look at the first line in the body of the `main` method.

```
double amountInAccount;
```

This line is called a variable declaration. Putting this line in your program is like saying, “I’m declaring my intention to have a variable named `amountInAccount` in my program.” This line reserves the name `amountInAccount` for your use in the program.

In this variable declaration, the word `double` is a Java keyword. This word `double` tells the computer what kinds of values you intend to store in `amountInAccount`. In particular, the word `double` stands for numbers between $-1.8 \times 10^{308}$ and $1.8 \times 10^{308}$. (These are enormous numbers with 308 zeros before the decimal point. Only the world’s richest people write checks with 308 zeros in them. The second of these numbers is one-point-eight
gazasso-zillion-kaskillion. The number $1.8 \times 10^{308}$, a constant defined by the International Bureau of Weights and Measures, is the number of eccentric computer programmers between Sunnyvale, California, and the M31 Andromeda Galaxy.)

More important than the humongous range of the double keyword’s numbers is the fact that a double value can have digits beyond the decimal point. After you declare `amountInAccount` to be of type `double`, you can store all sorts of numbers in `amountInAccount`. You can store 50.22, 0.02398479, or –3.0. In Listing 4-2, if I hadn’t declared `amountInAccount` to be of type `double`, I may not have been able to store 50.22. Instead, I would have had to store plain old 50, without any digits beyond the decimal point.

<table>
<thead>
<tr>
<th>Digits beyond the decimal point</th>
</tr>
</thead>
<tbody>
<tr>
<td>Java has two different types that have digits beyond the decimal point: type <code>double</code> and type <code>float</code>. So what’s the difference? When you declare a variable to be of type <code>double</code>, you’re telling the computer to keep track of 64 bits when it stores the variable’s values. When you declare a variable to be of type <code>float</code>, the computer keeps track of only 32 bits.</td>
</tr>
<tr>
<td>You could change Listing 4-2 and declare <code>amountInAccount</code> to be of type <code>float</code>.</td>
</tr>
<tr>
<td>```java</td>
</tr>
<tr>
<td>float amountInAccount;</td>
</tr>
<tr>
<td>```</td>
</tr>
<tr>
<td>Surely, 32 bits are enough to store a small number like 50.22. Well, they are and they aren’t. You could easily store 50.00 with only 32 bits. Heck, you could store 50.00 with only 6 bits. The size of the number doesn’t matter. It’s the accuracy that matters. In a 64-bit double variable, you’re using most of the bits to store stuff beyond the decimal point. To store the .22 part of 50.22, you need more than the measly 32 bits that you get with type <code>float</code>.</td>
</tr>
<tr>
<td>Do you really believe what you just read — that it takes more than 32 bits to store .22? To help convince you, I made a few changes to the code in Listing 4-2. I made <code>amountInAccount</code> be of type <code>float</code>, and the output I got was</td>
</tr>
<tr>
<td>```java</td>
</tr>
<tr>
<td>You have $1000050.25 in your account.</td>
</tr>
<tr>
<td>```</td>
</tr>
<tr>
<td>Compare this with the output in Figure 4-3. When I switch from type <code>double</code> to type <code>float</code>, Charles has an extra three cents in his account. By changing to the 32-bit <code>float</code> type, I’ve clobbered the accuracy in the <code>amountInAccount</code> variable’s hundredths place. That’s bad.</td>
</tr>
<tr>
<td>Another difficulty with <code>float</code> values is purely cosmetic. Look again at the literals, 50.22 and 1000000.00, in Listing 4-2. The Laws of Java say that literals like these take up 64 bits each. This means that if you declare <code>amountInAccount</code> to be of type <code>float</code>, you’re going to run into trouble. You’ll have trouble stuffing those 64-bit literals into your little 32-bit <code>amountInAccount</code> variable. To compensate, you can switch from double literals to float literals by adding an <code>F</code> to each double literal, but a number with an extra <code>F</code> at the end looks funny.</td>
</tr>
<tr>
<td>```java</td>
</tr>
<tr>
<td>float amountInAccount;</td>
</tr>
<tr>
<td>amountInAccount = 50.22F;</td>
</tr>
<tr>
<td>amountInAccount = amountInAccount + 1000000.00F;</td>
</tr>
<tr>
<td>```</td>
</tr>
<tr>
<td>To experiment with numbers, visit <a href="http://babbage.cs.qc.edu/courses/cs341/IEEE-754.html">http://babbage.cs.qc.edu/courses/cs341/IEEE-754.html</a>. The page takes any number that you enter and shows you how the number would be represented as 32 bits and as 64 bits.</td>
</tr>
</tbody>
</table>
Another type — type float — also allows you to have numbers after the decimal point, but this type isn’t as accurate. (See the sidebar, “Digits beyond the decimal point,” for the full story.) Don’t sweat the choice between float and double. For most programs, just use double.

### An Import Declaration

It’s always good to announce your intentions up front. Consider the following classroom lecture:

> “Today, in our History of Film course, we’ll be discussing the career of actor **Lionel Herbert Blythe Barrymore**.
>
> “Born in Philadelphia, **Barrymore** appeared in more than 200 films, including It’s a Wonderful Life, Key Largo, and Dr. Kildare’s Wedding Day. In addition, **Barrymore** was a writer, composer, and director. **Barrymore** did the voice of Ebenezer Scrooge every year on radio. . . .”

Interesting stuff, heh? Now compare the paragraphs above with a lecture in which the instructor doesn’t begin by introducing the subject:

> “Welcome once again to the History of Film.
>
> “Born in Philadelphia, **Lionel Barrymore** appeared in more than 200 films, including It’s a Wonderful Life, Key Largo, and Dr. Kildare’s Wedding Day. In addition, **Barrymore (not Ethel, John, or Drew)** was a writer, composer, and director. **Lionel Barrymore** did the voice of Ebenezer Scrooge every year on radio. . . .”

Without a proper introduction, a speaker may have to remind you constantly that the discussion is about Lionel Barrymore and not about some other Barrymore. The same is true in a Java program. Compare some code from Listings 3-1 and 4-2. From Listing 3-1:

```java
class Displayer {
    System.out.println("You'll love Java!");
}
```

and from Listing 4-2:

```java
import static java.lang.System.out;

class Millionaire {
    out.print("You have ");
    out.print(amountInAccount);
    out.println(" in your account.");
}
With Listing 4-2, you announce in your introduction (in your import declaration) that you’re using System.out in your Java class. You clarify what you mean by System with the full name java.lang.System. (Hey! Didn’t the first lecturer clarify with the full name “Lionel Herbert Blythe Barrymore?”) After having announced your intentions in the import declaration, you can use the abbreviated name out in your Java class code.

The details of this import stuff can be pretty nasty. So for now, just paste the import declaration in Listing 4-2 at the top of your Java programs. (Don’t bother pasting this import declaration into a program that doesn’t use System.out. It probably wouldn’t hurt anything, but it would look very strange to a veteran Java programmer.)

No single section in this book can present the entire story about import declarations. To begin untangling some of the import declaration’s subtleties, see Chapters 5, 9, and 10.

## Displaying Text

The last three statements in Listing 4-2 use a neat formatting trick. You want to display several different things on a single line on the screen. You put these things in separate statements. All but the last of the statements are calls to out.print. (The last statement is a call to out.println.) Calls to out.print display text on part of a line and then leave the cursor at the end of the current line. After executing out.print, the cursor is still at the end of the same line, so the next out.whatever can continue printing on that same line. With several calls to print capped off by a single call to println, the result is just one nice-looking line of output. (Refer to Figure 4-3.)

A call to out.print writes some things and leaves the cursor sitting at the end of the line of output. A call to out.println writes things and then finishes the job by moving the cursor to the start of a brand new line of output.

## Numbers without Decimal Points

“In 1995, the average family had 2.3 children.”

At this point, a wise guy always remarks that no real family has exactly 2.3 children. Clearly, whole numbers have a role in this world. So, in Java, you can declare a variable to store nothing but whole numbers. Listing 4-3 shows a program that uses whole number variables.
Listing 4-3: Using the int Type

```java
import static java.lang.System.out;

class ElevatorFitter {
    public static void main(String args[]) {
        int weightOfAPerson;
        int elevatorWeightLimit;
        int numberOfPeople;

        weightOfAPerson = 150;
        elevatorWeightLimit = 1400;
        numberOfPeople =
            elevatorWeightLimit / weightOfAPerson;

        out.print("You can fit ");
        out.print(numberOfPeople);
        out.println(" people on the elevator.");
    }
}
```

The story behind the program in Listing 4-3 takes some heavy-duty explaining. So here goes:

You have a hotel elevator whose weight capacity is 1,400 pounds. One weekend, the hotel hosts the Brickenchicker family reunion. In a certain branch of the Brickenchicker family are identical dectuplets (ten siblings, all with the same physical characteristics). Normally, each of the Brickenchicker dectuplets weighs exactly 145 pounds. But on Saturday, the family has a big catered lunch, and, because lunch included strawberry shortcake, each of the Brickenchicker dectuplets now weighs 150 pounds. Immediately after lunch, all ten of the Brickenchicker dectuplets arrive at the elevator at exactly the same time. (Why not? All ten of them think alike.) So, the question is, how many of the dectuplets can fit on the elevator?

Now remember, if you put one ounce more than 1,400 pounds of weight on the elevator, the elevator cable breaks, plunging all dectuplets on the elevator to their sudden (and costly) deaths.

The answer to the Brickenchicker riddle (the output of the program of Listing 4-3) is shown in Figure 4-4.
At the core of the Brickenchicker elevator problem, you’ve got whole numbers — numbers with no digits beyond the decimal point. When you divide 1,400 by 150, you get 9¹⁄₃, but you shouldn’t take the ¹⁄₃ seriously. No matter how hard you try, you can’t squeeze an extra 50 pounds worth of Brickenchicker dectuplet onto the elevator. This fact is reflected nicely in Java. In Listing 4-3, all three variables (weightOfAPerson, elevatorWeightLimit, and numberOfPeople) are of type int. An int value is a whole number. When you divide one int value by another (as you do with the slash in Listing 4-3), you get another int. When you divide 1,400 by 150, you get 9 — not ⁹⁄₃. You see this in Figure 4-4. Taken together, the following statements put the number 9 on the computer screen:

```java
numberOfPeople =
    elevatorWeightLimit / weightOfAPerson;
out.print(numberOfPeople);
```

### Combining Declarations and Initializing Variables

Look back at Listing 4-3. In that listing, you see three variable declarations — one for each of the program’s three int variables. I could have done the same thing with just one declaration:

```java
int weightOfAPerson, elevatorWeightLimit, numberOfPeople;
```

If two variables have completely different types, you can’t create both variables in the same declaration. For instance, to create an int variable named `weightOfFred` and a double variable named `amountInFredsAccount`, you need two separate variable declarations.
You can give variables their starting values in a declaration. In Listing 4-3 for instance, one declaration can replace several lines in the main method (all but the calls to print and println).

```java
int weightOfAPerson = 150, elevatorWeightLimit = 1400,
    numberOfPeople = elevatorWeightLimit / weightOfAPerson;
```

When you do this, you don’t say that you’re assigning values to variables. The pieces of the declarations with equal signs in them aren’t really called assignment statements. Instead, you say that you’re initializing the variables. Believe it or not, keeping this distinction in mind is helpful.

Like everything else in life, initializing a variable has advantages and disadvantages:

- **When you combine six lines of Listing 4-3 into just one declaration, the code becomes more concise.** Sometimes, concise code is easier to read. Sometimes it’s not. As a programmer, it’s your judgment call.

- **By initializing a variable, you may automatically avoid certain programming errors.** For an example, see Chapter 7.

- **In some situations, you have no choice. The nature of your code forces you either to initialize or not to initialize.** For an interesting example, see the deleting-evidence program in Chapter 6.

### The Atoms: Java’s Primitive Types

The words int and double, which I describe in the previous sections, are examples of primitive types (also known as simple types) in Java. The Java language has exactly eight primitive types. As a newcomer to Java, you can pretty much ignore all but four of these types. (As programming languages go, Java is nice and compact that way.) The complete list of primitive types is shown in Table 4-1.

<table>

</table>

The types that you shouldn’t ignore are int, double, char, and boolean. Previous sections in this chapter cover the int and double types. So, this section covers char and boolean types.

The char type

Not so long ago, people thought computers existed only for doing big number-crunching calculations. Nowadays, with word processors, nobody thinks that way anymore. So, if you haven’t been in a cryogenic freezing chamber for the last 20 years, you know that computers store letters, punctuation symbols, and other characters.

The Java type that’s used to store characters is called char. Listing 4-4 has a simple program that uses the char type. The output of the program of Listing 4-4 is shown in Figure 4-5.

Listing 4-4: Using the char Type

```java
class CharDemo {
    public static void main(String args[]) {
        char myLittleChar = 'b';
        char myBigChar = Character.toUpperCase(myLittleChar);
        System.out.println(myBigChar);
    }
}
```
In Listing 4-4, the first initialization stores the letter $b$ in the variable `myLittleChar`. In the initialization, notice how $b$ is surrounded by single quote marks. In Java, every `char` literal starts and ends with a single quote mark.

In a Java program, single quote marks surround the letter in a `char` literal.

If you need help sorting out the terms `assignment`, `declaration`, and `initialization`, see the “Combining Declarations and Initializing Variables” section, earlier in this chapter.

In the second initialization of Listing 4-4, the program calls an API method whose name is `Character.toUpperCase`. The `Character.toUpperCase` method does just what its name suggests — the method produces the uppercase equivalent of the letter $b$. This uppercase equivalent (the letter $B$) is assigned to the `myBigChar` variable, and the $B$ that’s in `myBigChar` is printed on the screen.

For an introduction to the Java Application Programming Interface (API), see Chapter 3.

If you’re tempted to write the following statement,

```java
char myLittleChars = 'barry';  //Don't do this
```

please resist the temptation. You can’t store more than one letter at a time in a `char` variable, and you can’t put more than one letter between a pair of single quotes. If you’re trying to store words or sentences (not just single letters), you need to use something called a `String`.

For a look at Java’s `String` type, see the section, “The Molecules and Compounds: Reference Types,” later in this chapter.

If you’re used to writing programs in other languages, you may be aware of something called ASCII Character Encoding. Most languages use ASCII; Java uses Unicode. In the old ASCII representation, each character takes up only 8 bits, but in Unicode, each character takes up 16 bits. Whereas ASCII stores the letters of the familiar Roman (English) alphabet, Unicode has room for characters from all the world’s languages. The only problem is that some of the API methods are geared specially toward the 16-bit code. Occasionally,
this bites you in the back. If you’re using a method to write Hello on the screen and Hello shows up instead, check the method’s documentation for mention of Unicode characters.

It’s worth noticing that the two methods, Character.toUpperCase and System.out.println, are used quite differently in Listing 4-4. The method Character.toUpperCase is called as part of an initialization or an assignment statement, but the method System.out.println is called on its own. To find out more about this, see Chapter 7.

The boolean type

A variable of type boolean stores one of two values — true or false. Listing 4-5 demonstrates the use of a boolean variable. The output of the program in Listing 4-5 is shown in Figure 4-6.

Listing 4-5: Using the boolean Type

```java
import static java.lang.System.out;

class ElevatorFitter2 {
    public static void main(String args[]) {
        out.println("True or False?");
        out.println("You can fit all ten of the");
        out.println("Brickenchicker dectuplets");
        out.println("on the elevator:");
        out.println();

        int weightOfAPerson = 150;
        int elevatorWeightLimit = 1400;
        int numberOfPeople =
            elevatorWeightLimit / weightOfAPerson;

        boolean allTenOkay = numberOfPeople >= 10;
        out.println(allTenOkay);
    }
}
```

Figure 4-6:
The Brickenchicker dectuplets strike again.
In Listing 4-5, the allTenOkay variable is of type boolean. To find a value for the allTenOkay variable, the program checks to see whether numberOfPeople is greater than or equal to ten. (The symbols >= stand for greater than or equal to.)

At this point, becoming fussy about terminology pays. Any part of a Java program that has a value is called an expression. If you write

```java
weightOfAPerson = 150;
```

then 150 is an expression (an expression whose value is the quantity 150). If you write

```java
numberOfEggs = 2 + 2;
```

then 2 + 2 is an expression (because 2 + 2 has the value 4). If you write

```java
int numberOfPeople = elevatorWeightLimit / weightOfAPerson;
```

then `elevatorWeightLimit / weightOfAPerson` is an expression. (The value of the expression `elevatorWeightLimit / weightOfAPerson` depends on whatever values the variables `elevatorWeightLimit` and `weightOfAPerson` have when the code containing the expression is executed.)

Any part of a Java program that has a value is called an expression.

In Listing 4-5, the code `numberOfPeople >= 10` is an expression. The expression’s value depends on the value stored in the `numberOfPeople` variable. But, as you know from seeing the strawberry shortcake at the Brickenchicker family’s catered lunch, the value of `numberOfPeople` isn’t greater than or equal to ten. This makes the value of `numberOfPeople >= 10` to be false. So, in the statement in Listing 4-5, in which allTenOkay is assigned a value, the allTenOkay variable is assigned a false value.

In Listing 4-5, I call `out.println()` with nothing inside the parentheses. When I do this, Java adds a line break to the program’s output. In Listing 4-5, `out.println()` tells the program to display a blank line.

---

The Molecules and Compounds:
Reference Types

By combining simple things, you get more complicated things. That’s the way it always goes. Take some of Java’s primitive types, whip them together to make a primitive type stew, and what do you get? A more complicated type called a reference type.
The program in Listing 4-6 uses reference types. Figure 4-7 shows you what happens when you run the program in Listing 4-6.

Listing 4-6: Using Reference Types

```java
import javax.swing.JFrame;

class ShowAFrame {
    public static void main(String args[]) {
        JFrame myFrame = new JFrame();
        String myTitle = "Blank Frame";

        myFrame.setTitle(myTitle);
        myFrame.setSize(200, 200);
        myFrame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
        myFrame.setVisible(true);
    }
}
```

The program in Listing 4-6 uses two references types. Both of these types are defined in the Java API. One of the types (the one that you’ll use all the time) is called `String`. The other type (the one that you can use to create GUIs) is called `JFrame`.

A `String` is a bunch of characters. It’s like having several `char` values in a row. So, with the `myTitle` variable declared to be of type `String`, assigning "Blank Frame" to the `myTitle` variable makes sense in Listing 4-6. The `String` class is declared in the Java API.

In a Java program, double quote marks surround the letters in a `String` literal.

A Java `JFrame` is a lot like a window. (The only difference is that you call it a `JFrame` instead of a window.) To keep Listing 4-6 short and sweet, I decided not to put anything in my frame — no buttons, no fields, nothing.
Even with a completely empty frame, Listing 4-6 uses tricks that I don’t describe until later in this book. So don’t try reading and interpreting every word of Listing 4-6. The big thing to get from Listing 4-6 is that the program has two variable declarations. In writing the program, I made up two variable names — myTitle and myFrame. According to the declarations, myTitle is of type String, and myFrame is of type JFrame.

You can look up String and JFrame in Java’s API documentation. But, even before you do, I can tell you what you’ll find. You’ll find that String and JFrame are the names of Java classes. So, that’s the big news. Every class is the name of a reference type. You can reserve amountInAccount for double values by writing

```java
double amountInAccount;
```

or by writing

```java
double amountInAccount = 50.22;
```

You can also reserve myFrame for a JFrame value by writing

```java
JFrame myFrame;
```

or by writing

```java
JFrame myFrame = new JFrame();
```

To review the notion of a Java class, see the sections on object-oriented programming (OOP) in Chapter 1.

Every Java class is a reference type. If you declare a variable to have some type that’s not a primitive type, the variable’s type is (most of the time) the name of a Java class.

Now, when you declare a variable to have type int, you can visualize what that declaration means in a fairly straightforward way. It means that, somewhere inside the computer’s memory, a storage location is reserved for that variable’s value. In that storage location is a bunch of bits. The arrangement of the bits assures that a certain whole number is represented.

That explanation is fine for primitive types like int or double, but what does it mean when you declare a variable to have a reference type? What does it mean to declare variable myFrame to be of type JFrame?

Well, what does it mean to declare i thank You God to be an E. E. Cummings poem? What would it mean to write the following declaration?

```java
EECummingsPoem ithankYouGod;
```
It means that a class of things is "EECummingsPoem," and "ithankYouGod" refers to an instance of that class. In other words, "ithankYouGod" is an object belonging to the "EECummingsPoem" class.

Because "JFrame" is a class, you can create objects from that class. (See Chapter 1.) Each such object (each instance of the JFrame class) is an actual frame — a window that appears on the screen when you run the code in Listing 4-6. By declaring the variable "myFrame" to be of type JFrame, you’re reserving the use of the name "myFrame." This reservation tells the computer that "myFrame" can refer to an actual JFrame-type object. In other words, "myFrame" can become a nickname for one of the windows that appears on the computer screen. The situation is illustrated in Figure 4-8.

When you declare ClassName variableName;,, you’re saying that a certain variable can refer to an instance of a particular class.

In Listing 4-6, the phrase JFrame myFrame reserves the use of the name "myFrame." On that same line of code, the phrase new JFrame() creates a new object (an instance of the JFrame class). Finally, that line’s equal sign makes "myFrame" refer to the new object. Knowing that the two words new JFrame() create an object can be very important. For a more thorough explanation of objects, see Chapter 7.
Creating New Values by Applying Operators

What could be more comforting than your old friend, the plus sign? It was the first thing that you learned about in elementary school math. Almost everybody knows how to add 2 and 2. In fact, in English usage, adding 2 and 2 is a metaphor for something that’s easy to do. Whenever you see a plus sign, a cell in your brain says, “Thank goodness — it could be something much more complicated.”

So Java has a plus sign. You can use it for several different purposes. You can use the plus sign to add two numbers, like this:

```java
int apples, oranges, fruit;
apples = 5;
oranges = 16;
fruit = apples + oranges;
```

You can also use the plus sign to paste `String` values together:

```java
String startOfChapter = 
    "It's three in the morning. I'm dreaming about the "+
    "history course that I failed in high school."
System.out.println(startOfChapter);
```
This can be handy because in Java, you’re not allowed to make a `String` straddle from one line to another. In other words, the following code wouldn’t work at all:

```java
String thisIsBadCode = 
    "It's three in the morning. I'm dreaming about the history course that I failed in high school."
System.out.println(thisIsBadCode);
```

The correct way to say that you’re pasting `String` values together is to say that you’re *concatenating* `String` values.

You can even use the plus sign to paste numbers next to `String` values.

```java
int apples, oranges, fruit;
apples = 5;
oranges = 16;
fruit = apples + oranges;
System.out.println("You have " + fruit + " pieces of fruit.");
```

Of course, the old minus sign is available too (but not for `String` values).

```java
apples = fruit - oranges;
```

Use an asterisk (*) for multiplication and a forward slash (/) for division.

```java
double rate, pay;
int hours;
rate = 6.25;
hours = 35;
pay = rate * hours;
System.out.println(pay);
```

For an example using division, refer to Listing 4-3.

When you divide an `int` value by another `int` value, you get an `int` value. The computer doesn’t round. Instead, the computer chops off any remainder. If you put `System.out.println(11 / 4)` in your program, the computer prints 2, not 2.75. To get past this, make either (or both) of the numbers you’re dividing `double` values. If you put `System.out.println(11.0 / 4)` in your program, the computer prints 2.75.

Another useful arithmetic operator is called the *remainder* operator. The symbol for the remainder operator is the percent sign (%). When you put `System.out.println(11 % 4)` in your program, the computer prints 3. It does this because 4 goes into 11 who-cares-how-many times with a remainder of 3. The remainder operator turns out to be fairly useful. Listing 4-7 has an example.
Listing 4-7: Making Change

```java
import static java.lang.System.out;

class MakeChange {
    public static void main(String args[]) {
        int total = 248;
        int quarters = total / 25;
        int whatsLeft = total % 25;

        int dimes = whatsLeft / 10;
        whatsLeft = whatsLeft % 10;

        int nickels = whatsLeft / 5;
        whatsLeft = whatsLeft % 5;

        int cents = whatsLeft;

        out.println("From "+ total + " cents you get");
        out.println(quarters + " quarters");
        out.println(dimes + " dimes");
        out.println(nickels + " nickels");
        out.println(cents + " cents");
    }
}
```

A run of the code in Listing 4-7 is shown in Figure 4-9. You start with a total of 248 cents. Then

```java
quarters = total / 25
```

divides 248 by 25, giving 9. That means you can make 9 quarters from 248 cents. Next,

```java
whatsLeft = total % 25
```

divides 248 by 25 again, and puts only the remainder, 23, into `whatsLeft`. Now you’re ready for the next step, which is to take as many dimes as you can out of 23 cents.

Figure 4-9: Change for $2.48.
Initialize once, assign often

Listing 4-7 has three lines that put values into the variable `whatsLeft`:

```java
int whatsLeft = total % 25;
whatsLeft = whatsLeft % 10;
whatsLeft = whatsLeft % 5;
```

Only one of these lines is a declaration. The other two lines are assignment statements. That’s good because you can’t declare the same variable more than once (not without creating something called a block). If you goof and write

```java
int whatsLeft = total % 25;
int whatsLeft = whatsLeft % 10;
```

in Listing 4-7, you see an error message (`whatsLeft is already defined`) when you try to compile your code.

To find out what a block is, see Chapter 5. Then, for some honest talk about redeclaring variables, see Chapter 10.

The increment and decrement operators

Java has some neat little operators that make life easier (for the computer’s processor, for your brain, and for your fingers). Altogether, four such operators exist — two increment operators and two decrement operators. The increment operators add 1, and the decrement operators subtract 1. The increment operators use double plus signs (`++`), and the decrement operators use double minus signs (`--`). To see how they work, you need some examples. The first example is in Figure 4-10.

A run of the program in Figure 4-10 is shown in Figure 4-11. In this horribly uneventful run, the count of bunnies is printed three times.

The double plus signs go by two different names, depending on where you put them. When you put the `++` before a variable, the `++` is called the `preincrement` operator. (The `pre` stands for `before`.)

The word `before` has two different meanings:

- **You put `++` before the variable.**
- **The computer adds 1 to the variable’s value before the variable is used in any other part of the statement.**
To understand this, look at the bold line in Figure 4-10. The computer adds 1 to \texttt{numberOfBunnies} (raising the value of \texttt{numberOfBunnies} to 29), and then the computer prints the number 29 on-screen.

With \texttt{out.println(++numberOfBunnies)}, the computer adds 1 to \texttt{numberOfBunnies} before printing the new value of \texttt{numberOfBunnies} on-screen.

An alternative to preincrement is \textit{postincrement}. (The \textit{post} stands for \textit{after}.) The word \textit{after} has two different meanings:

- You put \texttt{++} after the variable.
- The computer adds 1 to the variable’s value after the variable is used in any other part of the statement.

To see more clearly how postincrement works, look at the bold line in Figure 4-12. The computer prints the old value of \texttt{numberOfBunnies} (which is 28) on the screen, and then the computer adds 1 to \texttt{numberOfBunnies}, which raises the value of \texttt{numberOfBunnies} to 29.

With \texttt{out.println(numberOfBunnies++)}, the computer adds 1 to \texttt{numberOfBunnies} after printing the old value that \texttt{numberOfBunnies} already had.
A run of the code in Figure 4-12 is shown in Figure 4-13. Compare Figure 4-13 with the run in Figure 4-11:

- With preincrement in Figure 4-11, the second number is 29.
- With postincrement in Figure 4-13, the second number is 28.

In Figure 4-13, the number 29 doesn’t show up on-screen until the end of the run, when the computer executes one last `out.println(numberOfBunnies);`

Are you trying to decide between using preincrement or postincrement? Try no longer. Most programmers use postincrement. In a typical Java program, you often see things like `numberOfBunnies++`. You seldom see things like `++numberOfBunnies`.

In addition to preincrement and postincrement, Java has two operators that use `--`. These operators are called **predecrement** and **postdecrement**.

- With predecrement (`--numberOfBunnies`), the computer subtracts 1 from the variable’s value before the variable is used in the rest of the statement.
- With postdecrement (`numberOfBunnies--`), the computer subtracts 1 from the variable’s value after the variable is used in the rest of the statement.
Instead of writing `++numberOfBunnies`, you could achieve the same effect by writing `numberOfBunnies = numberOfBunnies + 1`. So some people conclude that Java’s `++` and `--` operators are for saving keystrokes — to keep those poor fingers from overworking themselves. This is entirely incorrect. The best reason for using `++` is to avoid the inefficient and error-prone practice of writing the same variable name, such as `numberOfBunnies`, twice in the same statement. If you write `numberOfBunnies` only once (as you do when you use `++` or `--`), the computer has to figure out what `numberOfBunnies` means only once. On top of that, when you write `numberOfBunnies` only once, you have only one chance (instead of two chances) to type the variable name incorrectly. With simple expressions like `numberOfBunnies++`, these advantages hardly make a difference. But with more complicated expressions, like `inventoryItems[(quantityReceived--*itemsPerBox+17)]++`, the efficiency and accuracy that you gain by using `++` and `--` is significant.
Assignment operators

If you read the preceding section, which is about operators that add 1, you may be wondering whether you can manipulate these operators to add 2 or add 5 or add 1000000. Can you write `numberOfBunnies++++` and still call yourself a Java programmer? Well, you can’t. If you try it, an error message appears when you try to compile your code.

So what can you do? As luck would have it, Java has plenty of assignment operators that you can use. With an assignment operator, you can add, subtract, multiply, or divide by anything you want. You can do other cool operations, too. Listing 4-8 has a smorgasbord of assignment operators (the things with equal signs). Figure 4-14 shows the output from running Listing 4-8.

Listing 4-8: Assignment Operators

```java
import static java.lang.System.out;

class UseAssignmentOperators {
    public static void main(String args[]) {
        int numberOfBunnies = 27;
        int numberExtra = 53;

        numberOfBunnies += 1;
        out.println(numberOfBunnies);

        numberOfBunnies += 5;
        out.println(numberOfBunnies);

        numberOfBunnies += numberExtra;
        out.println(numberOfBunnies);

        numberOfBunnies *= 2;
        out.println(numberOfBunnies);

        out.println(numberOfBunnies -= 7);
        out.println(numberOfBunnies = 100);
    }
}
```

Figure 4-14: A run of the code in Listing 4-8.

<td>100</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Process completed.
Listing 4-8 shows how versatile Java’s assignment operators are. With the assignment operators, you can add, subtract, multiply, or divide a variable by any number. Notice how `+= 5` adds 5 to `numberOfBunnies`, and how `*= 2` multiplies `numberOfBunnies` by 2. You can even use another expression’s value (in Listing 4-8, `numberExtra`) as the number to be applied.

The last two lines in Listing 4-8 demonstrate a special feature of Java’s assignment operators. You can use an assignment operator as part of a larger Java statement. In the next to last line of Listing 4-8, the operator subtracts 7 from `numberOfBunnies`, decreasing the value of `numberOfBunnies` from 172 to 165. But then the whole assignment business is stuffed into a call to `out.println`, so the number 165 is printed on the computer screen.

Lo and behold, the last line of Listing 4-8 shows how you can do the same thing with Java’s plain old equal sign. The thing that I call an assignment statement near the start of this chapter is really one of the assignment operators that I describe in this section. So, whenever you assign a value to something, you can make that assignment be part of a larger statement.

Each use of an assignment operator does double duty as both a statement and an expression. In all cases, the expression’s value equals whatever value you assign. For example, before executing the code `out.println(numberOfBunnies -= 7)`, the value of `numberOfBunnies` is 172. As a statement, `numberOfBunnies -= 7` tells the computer to subtract 7 from `numberOfBunnies` (so the value of `numberOfBunnies` goes from 172 down to 165). As an expression, the value of `numberOfBunnies -= 7` is 165. So the code `out.println(numberOfBunnies -= 7)` really means `out.println(165)`. The number 165 is displayed on the computer screen.

For a richer explanation of this kind of thing, see the sidebar, “Statements and expressions,” earlier in this chapter.
Chapter 5

Controlling Program Flow with Decision-Making Statements

In This Chapter

- Writing statements that choose between alternatives
- Putting statements inside one another
- Choosing among many alternatives

The TV show *Dennis the Menace* aired on CBS from 1959 to 1963. I remember one episode in which Mr. Wilson was having trouble making an important decision. I think it was something about changing jobs or moving to a new town. Anyway, I can still see that shot of Mr. Wilson sitting in his yard, sipping lemonade, and staring into nowhere for the whole afternoon. Of course, the annoying character Dennis was constantly interrupting Mr. Wilson’s peace and quiet. That’s what made this situation funny.

What impressed me about this episode (the reason why I remember it so clearly even now) was Mr. Wilson’s dogged intent in making the decision. This guy wasn’t going about his everyday business, roaming around the neighborhood, while thoughts about the decision wandered in and out of his mind. He was sitting quietly in his yard, making marks carefully and logically on his mental balance sheet. How many people actually make decisions this way?

At that time, I was still pretty young. I’d never faced the responsibility of having to make a big decision that affected my family and me. But I wondered what such a decision-making process would be like. Would it help to sit there like a stump for hours on end? Would I make my decisions by the careful weighing and tallying of options? Or would I shoot in the dark, take risks, and act on impulse? Only time would tell.
Making Decisions (Java if Statements)

When you’re writing computer programs, you’re constantly hitting forks in roads. Did the user correctly type his or her password? If yes, let the user work; if no, kick the bum out. So the Java programming language needs a way of making a program branch in one of two directions. Fortunately, the language has a way. It’s called an if statement.

Guess the number

The use of an if statement is illustrated in Listing 5-1. Two runs of the program in Listing 5-1 are shown in Figure 5-1.

Listing 5-1: A Guessing Game

```java
import static java.lang.System.out;
import java.util.Scanner;
import java.util.Random;

class GuessingGame {
    public static void main(String args[]) {
        Scanner myScanner = new Scanner(System.in);

        out.print("Enter an int from 1 to 10: ");

        int inputNumber = myScanner.nextInt();
        int randomNumber = new Random().nextInt(10) + 1;

        if (inputNumber == randomNumber) {
            out.println("**********");
            out.println("*You win.*");
            out.println("**********");
        } else {
            out.println("You lose.");
            out.println("The random number was ");
            out.println(randomNumber + ".");
        }

        out.println("Thank you for playing.");
    }
}
```
The program in Listing 5-1 plays a guessing game with the user. The program gets a number (a guess) from the user and then generates a random number between 1 and 10. If the number that the user entered is the same as the random number, the user wins. Otherwise, the user loses. In either case, the program tells the user what the random number was.

She controlled keystrokes from the keyboard

Taken together, the lines

```java
import java.util.Scanner;

Scanner myScanner = new Scanner(System.in);

int inputNumber = myScanner.nextInt();
```

in Listing 5-1 get whatever number the user types on the keyboard. The last of the three lines puts this number into a variable named `inputNumber`. If these lines look complicated, don't worry. You can copy these lines almost word for word whenever you want to read from the keyboard. Include the first two lines (the `import` and `Scanner` lines) just once in your program. Later in your program, wherever the user types an `int` value, include a line with a call to `nextInt` (as in the last of the three lines above).

Of all the names in these three lines of code, the only two names that I coined myself are `inputNumber` and `myScanner`. All the other names are part of Java. So, if I want to be creative, I can write the lines this way:

```java
import java.util.Scanner;

Scanner readingThingie = new Scanner(System.in);

int valueTypedIn = readingThingie.nextInt();
```
I can also beef up my program’s import declarations, as I do in Listings 5-2 and 5-3. Other than that, I have very little leeway.

As you read on in this book, you’ll start recognizing the patterns behind these three lines of code, so I don’t clutter up this section with all the details. For now, you can just copy these three lines and keep the following in mind:

- **When you import java.util.Scanner, you don’t use the word static.**
  Importing Scanner is different from importing System.out. When you import java.lang.System.out, you use the word static. (See Listing 5-1.)
  For the real story on the word static, see Chapter 10.

- **The name System.in stands for the keyboard.**
  To get characters from someplace other than the keyboard, you can type something other than System.in inside the parentheses.
  What else can you put inside the parentheses? For some ideas, see Chapter 8.

- **When you expect the user to type an int value (a whole number of some kind), use nextInt().**
  If you expect the user to type a double value (a number containing a decimal point), use nextDouble(). If you expect the user to type true or false, use nextBoolean(). If you expect the user to type a word (a word like Barry, Java, or Hello), use next().
  For an example in which the user types a word, see Listing 5-3. For an example in which the user types a single character, see Listing 6-4 in Chapter 6. For an example in which a program reads an entire line of text (all in one big gulp), see Chapter 8.

- **You can get several values from the keyboard, one after another.**
  To do this, use the myScanner.nextInt() code several times.
  To see a program that reads more than one value from the keyboard, go to Listing 5-4.

### Creating randomness

Achieving real randomness is surprisingly difficult. Mathematician Persi Diaconis says that if you flip a coin several times, always starting with the head side up, you’re likely to toss heads more often than tails. If you toss several more times, always starting with the tail side up, you’re likely to toss tails more often than heads. In other words, coin tossing isn’t really fair.*

Computers aren’t much better than coins and human thumbs. A computer mimics the generation of random sequences but, in the end, the computer just does what it’s told and does all this in a purely deterministic fashion. So in Listing 5-1, when the computer executes

```java
import java.util.Random;
int randomNumber = new Random().nextInt(10) + 1;
```

the computer appears to give us a randomly generated number — a whole number between 1 and 10. But it’s all a fake. The computer just follows instructions. It’s not really random, but without bending a computer over backwards, it’s the best that anyone can do.

Once again, I ask you to take this code on blind faith. Don’t worry about what `new Random().nextInt` means until you have more experience with Java. Just copy this code into your own programs and have fun with it. And if the numbers from 1 to 10 aren’t in your flight plans, don’t fret. To roll an imaginary die, write the statement

```java
int rollEmBaby = new Random().nextInt(6) + 1;
```

With the execution of this statement, the variable `rollEmBaby` gets a value from 1 to 6.

### The if statement

At the core of Listing 5-1 is a Java `if` statement. This `if` statement represents a fork in the road. (See Figure 5-2.) The computer follows one of two prongs — the prong that prints `You win` or the prong that prints `You lose`. The computer decides which prong to take by testing the truth or falsehood of a `condition`. In Listing 5-1, the condition being tested is

```java
inputNumber == randomNumber
```

Does the value of `inputNumber` equal the value of `randomNumber`? When the condition is true, the computer does the stuff between the condition and the word `else`. When the condition turns out to be false, the computer does the stuff after the word `else`. Either way, the computer goes on to execute the last `println` call, which displays `Thank you for playing`.

The condition in an `if` statement must be enclosed in parentheses. However, a line like `if(inputNumber == randomNumber)` is not a complete statement, so this line shouldn’t end with a semicolon.
Sometimes, when I’m writing about a condition that’s being tested, I slip into using the word *expression* instead of *condition*. That’s okay, because every condition is an expression. An expression is something that has a value and, sure enough, every condition has a value. The condition’s value is either *true* or *false*.(For revealing information about expressions, and values like *true* and *false*, see Chapter 4.)

**The double equal sign**

In Listing 5-1, in the *if* statement’s condition, notice the use of the double equal sign. Comparing two numbers to see whether they’re the same isn’t the same as setting something equal to something else. That’s why the symbol to compare for equality isn’t the same as the symbol that’s used in an assignment or an initialization. In an *if* statement’s condition, you can’t replace the double equal sign with a single equal sign. If you do, your program just won’t work. (You’ll almost always get an error message when you try to compile your code.)

On the other hand, if you never make the mistake of using a single equal sign in a condition, you’re not normal. Not long ago, while I was teaching an introductory Java course, I promised that I’d swallow my laser pointer if no one made the single equal sign mistake during any of the lab sessions. This wasn’t an idle promise. I knew I’d never have to keep it. As it turned out, even if I had ignored the first ten times anybody made the single equal sign mistake during those lab sessions, I would still be laser-pointer free. Everybody mistakenly uses the single equal sign several times in his or her programming
career. The trick is not to avoid making the mistake; the trick is to catch the mistake whenever you make it.

**Brace yourself**

The if statement in Listing 5-1 has two halves — a top half and a bottom half. I have names for these two parts of an if statement. I call them the *if part* (the top half) and the *else part* (the bottom half).

The if part in Listing 5-1 seems to have more than one statement in it. I make this happen by enclosing the three statements of the if part in a pair of curly braces. When I do this, I form a block. A block is a bunch of statements scrunched together by a pair of curly braces.

With this block, three calls to println are tucked away safely inside the if part. With the curly braces, the rows of asterisks and the words You win are displayed only when the user’s guess is correct.

This business with blocks and curly braces applies to the else part as well. In Listing 5-1, whenever inputNumber doesn’t equal randomNumber, the computer executes three print/println calls. To convince the computer that all three of these calls are inside the else clause, I put these calls into a block. That is, I enclose these three calls in a pair of curly braces.

Strictly speaking, Listing 5-1 has only one statement between the if and the else statements, and only one statement after the else statement. The trick is that when you surround a bunch of statements inside curly braces, you get a block, and a block behaves, in all respects, like a single statement. In fact, the official Java documentation lists blocks as one of the many kinds of statements. So, in Listing 5-1, the block that prints You win and asterisks is a single statement. It’s a statement that has, within it, three smaller statements.

**Indenting if statements in your code**

Notice how, in Listing 5-1, the print and println calls inside the if statement are indented. (This includes both the You win and You lose statements. The print and println calls that come after the word else are still part of the if statement.) Strictly speaking, you don’t have to indent the statements that are inside an if statement. For all the compiler cares, you can write your whole program on a single line or place all your statements in an artful, misshapen zigzag. The problem is that if you don’t indent your statements in some logical fashion, neither you nor anyone else can make sense of your code. In Listing 5-1, the indenting of the print and println statements helps your eye (and brain) see quickly that these statements are subordinate to the overall if/else flow.
In a small program, unindented or poorly indented code is barely tolerable. But in a complicated program, indentation that doesn’t follow a neat, logical pattern is a big, ugly nightmare.

When you write if statements, you may be tempted to chuck all the rules about curly braces out the window and just rely on indentation. Unfortunately, this seldom works. If you indent three statements after the word else and forget to enclose those statements in curly braces, the computer thinks that the else part includes only the first of the three statements. What’s worse, the indentation misleads you into believing that the else part includes all three statements. This makes it more difficult for you to figure out why your code isn’t behaving the way you think it should behave. So watch those braces!

**Elseless in Ifrica**

Okay, so the title of this section is contrived. Big deal! The idea is that you can create an if statement without the else part. Take, for instance, the code in Listing 5-1. Maybe you’d rather not rub it in whenever the user loses the game. The modified code in Listing 5-2 shows you how to do this (and Figure 5-3 shows you the result).

**Listing 5-2: A Kinder, Gentler Guessing Game**

```java
import static java.lang.System.in;
import static java.lang.System.out;
import java.util.Scanner;
import java.util.Random;
class DontTellThemTheyLost {
    public static void main(String args[]) {
        Scanner myScanner = new Scanner(in);
        out.print("Enter an int from 1 to 10: ");
        int inputNumber = myScanner.nextInt();
        int randomNumber = new Random().nextInt(10) + 1;

        if (inputNumber == randomNumber) {
            out.println("*You win.*");
        }
        out.println("That was a very good guess :-)");
        out.print("The random number was ");
        out.println(randomNumber + ".");
        out.println("Thank you for playing.");
    }
}
```
The `if` statement in Listing 5-2 has no `else` part. When `inputNumber` is the same as `randomNumber`, the computer prints `You win`. When `inputNumber` is different from `randomNumber`, the computer doesn’t print `You win`.

Listing 5-2 illustrates another new idea. With an `import` declaration for `System.in`, I can reduce `new Scanner(System.in)` to the shorter `new Scanner(in)`. Adding this `import` declaration is hardly worth the effort. In fact, I do more typing with the `import` declaration than without it. Nevertheless, the code in Listing 5-2 demonstrates that it’s possible to import `System.in`.

### Forming Conditions with Comparisons and Logical Operators

The Java programming language has plenty of little squiggles and doodads for your various condition-forming needs. This section tells you all about them.

#### Comparing numbers; comparing characters

Table 5-1 shows you the operators that you can use to compare things with one another.

<table>
<thead>
<tr>
<th>Table 5-1 Comparison Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Operator Symbol</strong></td>
</tr>
<tr>
<td><code>==</code></td>
</tr>
<tr>
<td><code>!=</code></td>
</tr>
<tr>
<td><code>&lt;</code></td>
</tr>
<tr>
<td><code>&gt;</code></td>
</tr>
<tr>
<td><code>&lt;=</code></td>
</tr>
<tr>
<td><code>&gt;=</code></td>
</tr>
</tbody>
</table>
You can use all of Java’s comparison operators to compare numbers and characters. When you compare numbers, things go pretty much the way you think they should go. But when you compare characters, things are a little strange. Comparing uppercase letters with one another is no problem. Because the letter B comes alphabetically before H, the condition 'B' < 'H' is true. Comparing lowercase letters with one another is also okay. What’s strange is that when you compare an uppercase letter with a lowercase letter, the uppercase letter is always smaller. So, even though 'Z' < 'A' is false, 'Z' < 'a' is true.

Under the hood, the letters A through Z are stored with numeric codes 65 through 90. The letters a through z are stored with codes 97 through 122. That’s why each uppercase letter is smaller than each lowercase letter.

Be careful when you compare two numbers for equality (with ==) or inequality (with !=). After doing some calculations and obtaining two double values or two float values, the values that you have are seldom dead-on equal to one another. (The problem comes from those pesky digits beyond the decimal point.) For instance, the Fahrenheit equivalent of 21 degrees Celsius is 69.8, and when you calculate 9.0 / 5 * 21 + 32 by hand, you get 69.8. But the condition 9.0 / 5 * 21 + 32 == 69.8 turns out to be false. That’s because, when the computer calculates 9.0 / 5 * 21 + 32, it gets 69.80000000000001, not 69.8.

Comparing objects

When you start working with objects, you’ll find that you can use == and != to compare objects with one another. For instance, a button that you see on the computer screen is an object. You can ask whether the thing that was just mouse-clicked is a particular button on your screen. You do this with Java’s equality operator.

```java
if (e.getSource() == bCopy) {
    clipboard.setText(which.getText());
}
```

To find out more about responding to button clicks, read Chapter 16 on this book’s CD-ROM.

The big gotcha with Java’s comparison scheme comes when you compare two strings. (For a word or two about Java’s String type, see the section about reference types in Chapter 4.) When you compare two strings with one another, you don’t want to use the double equal sign. Using the double equal sign would ask, “Is this string stored in exactly the same place in memory as that other string?” That’s usually not what you want to ask. Instead, you usually want to ask, “Does this string have the same characters in it as that other string?” To ask the second question (the more appropriate question) Java’s
String type has a method named equals. (Like everything else in the known universe, this equals method is defined in the Java API, short for Application Programming Interface.) The equals method compares two strings to see whether they have the same characters in them. For an example using Java’s equals method, see Listing 5-3. (A run of the program in Listing 5-3 is shown in Figure 5-4.)

**Listing 5-3: Checking a Password**

```java
import static java.lang.System.*;
import java.util.Scanner;

class CheckPassword {
    public static void main(String args[]) {
        out.print("What's the password? ");
        Scanner myScanner = new Scanner(in);
        String password = myScanner.next();
        out.println("You typed >>" + password + "<<");
        out.println();
        if (password == "swordfish") {
            out.println("The word you typed is stored");
            out.println("in the same place as the real");
            out.println("password. You must be a");
            out.println("hacker.");
        } else {
            out.println("The word you typed is not");
            out.println("stored in the same place as");
            out.println("the real password, but that's");
            out.println("no big deal.");
        }
        out.println();
        if (password.equals("swordfish")) {
            out.println("The word you typed has the");
            out.println("same characters as the real");
            out.println("password. You can use our");
            out.println("precious system.");
        } else {
            out.println("The word you typed doesn't");
            out.println("have the same characters as");
            out.println("the real password. You can't");
            out.println("use our precious system.");
        }
    }
}
```
In Listing 5-3, the call `myScanner.next()` grabs whatever word the user types on the computer keyboard. The code shoves this word into the variable named `password`. Then the program's if statements use two different techniques to compare `password` with "swordfish".

The more appropriate of the two techniques uses Java's `equals` method. The `equals` method looks funny when you call it, because you put a dot after one string and put the other string in parentheses. But that's the way you have to do it.

In calling Java's `equals` method, it doesn't matter which string gets the dot and which gets the parentheses. For instance, in Listing 5-3, you could have written

```java
if ("swordfish".equals(password))
```

The method would work just as well.

A call to Java's `equals` method looks imbalanced, but it's not. There's a reason behind the apparent imbalance between the dot and the parentheses. The idea is that you have two objects: the `password` object and the "swordfish" object. Each of these two objects is of type `String`. (However, `password` is a variable of type `String`, and "swordfish" is a `String literal`.) When you write `password.equals("swordfish")`, you're calling an `equals` method that belongs to the `password` object. As you call that method, you're feeding "swordfish" to the method as the method's parameter (pun intended).

You can read more about methods belonging to objects in Chapter 7.

When comparing strings with one another, use the `equals` method, not the double equal sign.
Importing everything in one fell swoop

The first line of Listing 5-3 illustrates a lazy way of importing both System.out and System.in. To import everything that System has to offer, you use the asterisk wildcard character (*). In fact, importing java.lang.System.* is like having about 30 separate import declarations, including System.in, System.out, System.err, System.nanoTime, and many other System things.

The use of an asterisk in an import declaration is generally considered bad programming practice, so I don’t do it often in this book’s examples. But for larger programs — programs that use dozens of names from the Java API — the lazy asterisk trick is handy.

You can’t toss an asterisk anywhere you want inside an import declaration. For example, you can’t import everything starting with java by writing import java.*. You can substitute an asterisk only for the name of a class or for the name of something static that’s tucked away inside a class. For more information about asterisks in import declarations, see Chapter 9. For information about static things, see Chapter 10.

Java’s logical operators

Mr. Spock would be pleased. Java has all the operators that you need for mixing and matching logical tests. The operators are shown in Table 5-2.

<table>
<thead>
<tr>
<th>Table 5-2 Logical Operators</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Operator Symbol</strong></td>
</tr>
<tr>
<td>&amp; &amp;</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>!</td>
</tr>
</tbody>
</table>

You can use these operators to form all kinds of elaborate conditions. Listing 5-4 has an example.
Listing 5-4: Checking Username and Password

```java
import static java.lang.System.out;
import java.util.Scanner;

class Authenticator {
    public static void main(String args[]) {
        Scanner myScanner = new Scanner(System.in);
        out.print("Username: ");
        String username = myScanner.next();
        out.print("Password: ");
        String password = myScanner.next();
        if (username.equals("bburd") && password.equals("swordfish")] || 
            (username.equals("hritter") && password.equals("preakston"))
        )
            { out.println("You're in.");
        } else {
            out.println("You're suspicious.");
        }
    }
}
```

Some runs of the program of Listing 5-4 are shown in Figure 5-5. When the username is `bburd` and the password is `swordfish` or when the username is `hritter` and the password is `preakston`, the user gets a nice message. Otherwise, the user is a bum who gets the nasty message that he or she deserves.

Keep an eye on those parentheses! When you’re combining comparisons with logical operators, it’s better to waste typing effort and add unneeded parentheses than to goof up your result by using too few parentheses. Take, for example, the expression
2 < 5 || 100 < 6 && 27 < 1

By misreading this expression, you may come to the conclusion that the expression is false. That is, you could wrongly read the expression as meaning \((\text{something-or-other}) \&\& 27 < 1\). Because \(27 < 1\) is false, you would conclude that the whole expression is false. The fact is that, in Java, any \&\& operator is evaluated before any || operator. So the expression really asks if \(2 < 5 || (\text{something-or-other})\). Because \(2 < 5\) is true, the whole expression is true.

To change the expression’s value from \text{true} to \text{false}, you can put the expression’s first two comparisons in parentheses, like this:

\((2 < 5 || 100 < 6) \&\& 27 < 1\)

Java’s || operator is \textit{inclusive}. This means that you get a \text{true} value whenever the thing on the left side is true, the thing on the right side is true, or both things are true. For instance, the expression \(2 < 10 || 20 < 30\) is true.

In Java, you can’t combine comparisons the way you do in ordinary English. In English, you may say, “We’ll have between three and ten people at the dinner table.” But in Java, you get an error message if you write \(3 \leq \text{people} \leq 10\). To do this comparison, you need something like \(3 \leq \text{people} \&\& \text{people} \leq 10\).

**Building a Nest**

Have you seen those cute Russian Matryoshka nesting dolls? Open up one, and another one is inside. Open up the other, and a third one is inside it. You can do the same thing with Java’s if statements. (Talk about fun!) Listing 5-5 shows you how.

**Listing 5-5: Nested if Statements**

```java
import static java.lang.System.out;
import java.util.Scanner;

class Authenticator2 {
    public static void main(String args[]) {
        Scanner myScanner = new Scanner(System.in);

        out.println("Username: ");
        String username = myScanner.next();
```

(continued)
Listing 5-5 (continued)

```java
if (username.equals("bburd")) {
    out.print("Password: ");
    String password = myScanner.next();
    if (password.equals("swordfish")) {
        out.println("You're in.");
    } else {
        out.println("Incorrect password");
    }
} else {
    out.println("Unknown user");
}
```

Figure 5-6 shows several runs of the code in Listing 5-5. The main idea is that to log on, you have to pass two tests. (In other words, two conditions must be true.) The first condition tests for a valid username; the second condition tests for the correct password. If you pass the first test (the username test), you march right into another if statement that performs a second test (the password test). If you fail the first test, you never make it to the second test. The overall plan is shown in Figure 5-7.

The code in Listing 5-5 does a good job with nested if statements, but it does a terrible job with real-world user authentication. First of all, never show a password in plain view (without asterisks to masquerade the password). Second, don’t handle passwords without encrypting them. Third, don’t tell the malicious user which of the two words (the username or the password) was entered incorrectly. Fourth . . . well I could go on and on. The code in Listing 5-5 just isn’t meant to illustrate good username/password practices.
Choosing among Many Alternatives (Java switch Statements)

I’m the first to admit that I hate making decisions. If things go wrong, I would rather have the problem be someone else’s fault. Writing the previous sections (on making decisions with Java’s `if` statement) knocked the stuffing right out of me. That’s why my mind boggles as I begin this section on choosing among many alternatives. What a relief it is to have that confession out of the way!

Figure 5-7: Don’t try eating with this fork.
Your basic switch statement

Now, it’s time to explore situations in which you have a decision with many branches. Take, for instance, the popular campfire song “Al’s All Wet.” (For a review of the lyrics, see the sidebar.) You’re eager to write code that prints this song’s lyrics. Fortunately, you don’t have to type all the words over and over again. Instead, you can take advantage of the repetition in the lyrics.

A complete program to display the “Al’s All Wet” lyrics won’t come until Chapter 6. In the meantime, assume that you have a variable named verse. The value of verse is 1, 2, 3, or 4, depending on which verse of “Al’s All Wet” you’re trying to print. You could have a big, clumsy bunch of if statements that checks each possible verse number.

```java
if (verse == 1) {
    out.println("That's because he has no brain.");
}
if (verse == 2) {
    out.println("That's because he is a pain.");
}
if (verse == 3) {
    out.println("'Cause this is the last refrain.");
}
```

**“Al’s All Wet”**

Sung to the tune of “Gentille Alouette”:

Al’s all wet. Oh, why is Al all wet? Oh,
Al’s all wet ’cause he’s standing in the rain.
Why is Al out in the rain?
That’s because he has no brain.
Has no brain, has no brain,
In the rain, in the rain.
Ohhhhhhh. . .

Al’s all wet. Oh, why is Al all wet? Oh,
Al’s all wet ’cause he’s standing in the rain.
Why is Al out in the rain?
That’s because he is a pain.
He’s a pain, he’s a pain,
Has no brain, has no brain,
In the rain, in the rain.
Ohhhhhhh. . .

Al’s all wet. Oh, why is Al all wet? Oh,
Al’s all wet ’cause he’s standing in the rain.
Why is Al out in the rain?
’Cause this is the last refrain.
Last refrain, last refrain,
He’s a pain, he’s a pain,
Has no brain, has no brain,
In the rain, in the rain.
Ohhhhhhh. . .

Al’s all wet. Oh, why is Al all wet? Oh,
Al’s all wet ’cause he’s standing in the rain.

–Harriet Ritter and Barry Burd
But that approach seems wasteful. Why not create a statement that checks the value of `verse` just once and then takes an action based on the value that it finds? Fortunately, just such a statement exists. It’s called a `switch` statement. Listing 5-6 has an example of a `switch` statement.

### Listing 5-6:  A switch Statement

```java
import static java.lang.System.out;
import java.util.Scanner;

class JustSwitchIt {
    public static void main(String args[]) {
        Scanner myScanner = new Scanner(System.in);
        out.print("Which verse? ");
        int verse = myScanner.nextInt();

        switch (verse) {
            case 1:
                out.println("That's because he has no brain.");
                break;
            case 2:
                out.println("That's because he is a pain.");
                break;
            case 3:
                out.println("'Cause this is the last refrain.");
                break;
            default:
                out.println("No such verse. Please try again.");
                break;
        }
        out.println("Ohhhhhhhhh. . .");
    }
}
```

Figure 5-8 shows two runs of the program in Listing 5-6. (The overall idea behind the program is illustrated in Figure 5-9.) First, the user types a number, like the number 2. Then, execution of the program reaches the top of the `switch` statement. The computer checks the value of the `verse` variable. When the computer determines that the `verse` variable's value is 2, the computer checks each case of the `switch` statement. The value 2 doesn’t match the topmost case, so the computer proceeds on to the middle of the three cases. The value posted for the middle case (the number 2) matches the value of the `verse` variable, so the computer executes the statements that come immediately after case 2. These two statements are
out.println("That's because he is a pain.");
break;

The first of the two statements displays the line That's because he is a pain. on the screen. The second statement is called a break statement. (What a surprise!) When the computer encounters a break statement, the computer jumps out of whatever switch statement it's in. So, in Listing 5-6, the computer skips right past the case that would display 'Cause this is the last refrain. In fact, the computer jumps out of the entire switch statement and goes straight to the statement just after the end of the switch statement. The computer displays Ohhhhhhh... because that's what the statement after the switch statement tells the computer to do.

Figure 5-8: Running the code of Listing 5-6.

Figure 5-9: The big fork in the code of Listing 5-6.

If the pesky user asks for verse 6, the computer responds by dropping past cases 1, 2, and 3. Instead, the computer does the default. In the default, the computer displays No such verse. Please try again, and then breaks
out of the switch statement. After the computer is out of the switch statement, the computer displays Ohhhhhhhhh.

You don’t really need to put a break at the very end of a switch statement. In Listing 5-6, the last break (the break that’s part of the default) is just for the sake of overall tidiness.

To break or not to break

In every Java programmer’s life, a time comes when he or she forgets to use break statements. At first, the resulting output is confusing, but then the programmer remembers fall-through. The term fall-through describes what happens when you end a case without a break statement. What happens is that execution of the code falls right through to the next case in line. Execution keeps falling through until you eventually reach a break statement or the end of the entire switch statement.

Usually, when you’re using a switch statement, you don’t want fall-through, so you pepper break statements throughout the switch statements. But, occasionally, fall-through is just the thing you need. Take, for instance, the “Al’s All Wet” song. (The classy lyrics are shown in the sidebar bearing the song’s name.) Each verse of “Al’s All Wet” adds new lines in addition to the lines from previous verses. This situation (accumulating lines from one verse to another) cries out for a switch statement with fall-through. Listing 5-7 demonstrates the idea.

Listing 5-7: A switch Statement with Fall-Through

```java
import static java.lang.System.out;
import java.util.Scanner;

class FallingForYou {
    public static void main(String args[]) {
        Scanner myScanner = new Scanner(System.in);
        out.print("Which verse? ");
        int verse = myScanner.nextInt();

        switch (verse) {
            case 3:
                out.print("Last refrain, ");
                out.println("last refrain,");
            case 2:
                out.print("He's a pain, ");
                out.println("he's a pain,");
        }
    }
}
```

(continued)
Listing 5-7 (continued)

```java
case 1:
    out.print("Has no brain, ");
    out.println("has no brain.");
}

    out.println("In the rain, in the rain.");
    out.println("Ohhhhhhhh...");
    out.println();

Figure 5-10 shows several runs of the program in Listing 5-7. Because the switch has no break statements in it, fall-through happens all over the place. For instance, when the user selects verse 2, the computer executes the two statements in case 2:

```java
    out.print ("He's a pain, ");
    out.println("he's a pain.");
```

Then, the computer marches right on to execute the two statements in case 1:

```java
    out.print ("Has no brain, ");
    out.println("has no brain.");
```

That's good, because the song's second verse has all these lines in it.

```
\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{Listing5-7.png}
\caption{Running the code of Listing 5-7.}
\end{figure}
```

Notice what happens when the user asks for verse 6. The switch statement in Listing 5-7 has no case 6 and no default, so none of the actions inside the switch statement are executed. Even so, with statements that print \texttt{In the rain, in the rain} and \texttt{Ohhhhhhh} right after the switch statement, the computer displays something when the user asks for verse 6.
In 1966, the company that brings you Head & Shoulders shampoo made history. On the back of the bottle, the directions for using the shampoo read, “LATHER-RINSE-REPEAT.” Never before had a complete set of directions (for doing anything, let alone shampooing your hair) been summarized so succinctly. People in the direction-writing business hailed this as a monumental achievement. Directions like these stood in stark contrast to others of the time. (For instance, the first sentence on a can of bug spray read, “Turn this can so that it points away from your face.” Duh!)

Aside from their brevity, the thing that made the Head & Shoulders directions so cool was that, with three simple words, they managed to capture a notion that’s at the heart of all instruction giving — the notion of repetition. That last word, REPEAT, took an otherwise bland instructional drone and turned it into a sophisticated recipe for action.

The fundamental idea is that when you’re following directions, you don’t just follow one instruction after another. Instead, you take turns in the road. You make decisions (“If HAIR IS DRY, then USE CONDITIONER,”) and you go into loops (“LATHER-RINSE, and then LATHER-RINSE again.”). In computer programming, you use decision making and looping all the time. This chapter explores looping in Java.
Repeating Instructions Over and Over Again (Java while Statements)

Here’s a guessing game for you. The computer generates a random number from 1 to 10. The computer asks you to guess the number. If you guess incorrectly, the game continues. As soon as you guess correctly, the game is over. The program to play the game is shown in Listing 6-1, and a round of play is shown in Figure 6-1.

Listing 6-1: A Repeating Guessing Game

```java
import static java.lang.System.out;
import java.util.Scanner;
import java.util.Random;

class GuessAgain {
    public static void main(String args[]) {
        Scanner myScanner = new Scanner(System.in);
        int numGuesses = 0;
        int randomNumber = new Random().nextInt(10) + 1;

        out.println("************");
        out.println("Welcome to the Guessing Game");
        out.println("************");
        out.println();

        out.print("Enter an int from 1 to 10: ");
        int inputNumber = myScanner.nextInt();
        numGuesses++;

        while (inputNumber != randomNumber) {
            out.println();
            out.println("Try again...");
            out.print("Enter an int from 1 to 10: ");
            inputNumber = myScanner.nextInt();
            numGuesses++;
        }

        out.print("You win after ");
        out.println(numGuesses + " guesses.");
    }
}
```
In Figure 6-1, the user makes four guesses. Each time around, the computer checks to see whether the guess is correct. An incorrect guess generates a request to try again. For a correct guess, the user gets a rousing You win, along with a tally of the number of guesses he or she made. The computer repeats several statements over and over again, checking each time through to see whether the user’s guess is the same as a certain randomly generated number. Each time the user makes a guess, the computer adds 1 to its tally of guesses. When the user makes the correct guess, the computer displays that tally. The flow of action is illustrated in Figure 6-2.

---

**Figure 6-1:**
Play until you drop.

**Figure 6-2:**
Around and around you go.
When you look over Listing 6-1, you see the code that does all this work. At the core of the code is a thing called a \textit{while statement} (also known as a \textit{while loop}). Rephrased in English, the \textit{while} statement would say

\begin{verbatim}
while the inputNumber is not equal to the randomNumber
keep doing all the stuff in curly braces: {

}
\end{verbatim}

The stuff in curly braces (the stuff that repeats over and over again) is the code that prints \textit{Try again, and then Enter an int . . .} gets a value from the keyboard and adds 1 to the count of the user’s guesses.

When you’re dealing with counters, like \texttt{numGuesses} in Listing 6-1, you may easily become confused and be off by 1 in either direction. You can avoid this headache by making sure that the \texttt{++} statements stay close to the statements whose events you’re counting. For example, in Listing 6-1, the variable \texttt{numGuesses} starts off with a value of 0. That’s because, when the program starts running, the user hasn’t made any guesses. Later in the program, right after each call to \texttt{myScanner.nextInt}, is a \texttt{numGuesses++} statement. That’s how you do it — you increment the counter as soon as the user enters another guess.

The statements in curly braces are repeated as long as \texttt{inputNumber != randomNumber} keeps being true. Each repetition of the statements in the loop is called an \textit{iteration} of the loop. In Figure 6-1, the loop undergoes three iterations. (If you don’t believe that Figure 6-1 has exactly three iterations, count the number of \textit{Try again} printings in the program’s output. A \textit{Try again} appears for each incorrect guess.)

When, at long last, the user enters the correct guess, the computer goes back to the top of the \textit{while} statement, checks the condition in parentheses, and finds itself in double negative land. The not equal (\texttt{! =}) relationship between \texttt{inputNumber} and \texttt{randomNumber} no longer holds. In other words, the \textit{while} statement’s condition, \texttt{inputNumber != randomNumber}, has become false. Because the \textit{while} statement’s condition is false, the computer jumps past the \textit{while} loop and goes on to the statements just below the \textit{while} loop. In these two statements, the computer prints \textit{You win after 4 guesses.}

With code of the kind shown in Listing 6-1, the computer never jumps out in mid-loop. When the computer finds that \texttt{inputNumber} isn’t equal to \texttt{randomNumber}, the computer marches on and executes all five statements inside the loop’s curly braces. The computer performs the test again (to see whether \texttt{inputNumber} is still not equal to \texttt{randomNumber}) only after it fully executes all five statements in the loop.
Repeating a Certain Number of Times 
(Java for Statements)

“Write ‘I will not talk in class’ on the blackboard 100 times.”

What your teacher really meant was,

- Set the count to 0.
- As long as the count is less than 100,
  - Write 'I will not talk in class' on the blackboard.
  - Add 1 to the count.

Fortunately, you didn’t know about loops and counters at the time. If you pointed all this stuff out to your teacher, you’d have gotten into a lot more trouble than you were already in.

One way or another, life is filled with examples of counting loops. And computer programming mirrors life — or is it the other way around? When you tell a computer what to do, you’re often telling the computer to print three lines, process ten accounts, dial a million phone numbers, or whatever. Because counting loops are so common in programming, the people who create programming languages have developed statements just for loops of this kind. In Java, the statement that repeats something a certain number of times is called a for statement. The use of the for statement is illustrated in Listings 6-2 and 6-3. Listing 6-2 has a rock-bottom simple example, and Listing 6-3 has a more exotic example. Take your pick.

Listing 6-2: The World’s Most Boring for Loop

```java
import static java.lang.System.out;

class Yawn {
    public static void main(String args[]) {
        for (int count = 1; count <= 10; count++) {
            out.print("The value of count is ");
            out.print(count);
            out.println(",");
        }
        out.println("Done!");
    }
}
```
Figure 6-3 shows you what you get when you run the program of Listing 6-2. (You get exactly what you deserve.) The for statement in Listing 6-2 starts by setting the count variable equal to 1. Then the statement tests to make sure that count is less than or equal to 10 (which it certainly is). Then the for statement dives ahead and executes the printing statements between the curly braces. (At this early stage of the game, the computer prints The value of count is 1.) Finally, the for statement does that last thing inside its parentheses — it adds 1 to the value of count.

With count now equal to 2, the for statement checks again to make sure that count is less than or equal to 10. (Yes, 2 is smaller than 10.) Because the test turns out okay, the for statement marches back into the curly braced statements and prints The value of count is 2 on the screen. Finally, the for statement does that last thing inside its parentheses — it adds 1 to the value of count, increasing the value of count to 3.

And so on. This whole thing keeps being repeated over and over again until, after 10 iterations, the value of count finally reaches 11. When this happens, the check for count being less than or equal to 10 fails, and the loop’s execution ends. The computer jumps to whatever statement comes immediately after the for statement. In Listing 6-2, the computer prints Done! The whole process is illustrated in Figure 6-4.

The anatomy of a for statement

After the word for, you always put three things in parentheses. The first of these three things is called an initialization, the second is an expression, and the third thing is called an update.

```
for ( initialization ; expression ; update )
```
Each of the three items in parentheses plays its own distinct role:

- The initialization is executed once, when the run of your program first reaches the for statement.
- The expression is evaluated several times (before each iteration).
- The update is also evaluated several times (at the end of each iteration).

If it helps, think of the loop as if its text is shifted all around:

```java
int count = 1
for (count <= 10 {  
    out.print("The value of count is ");  
    out.print(count);  
    out.println(".");  
    count++  
}
```

You can’t write a real for statement this way. Even so, this is the order in which the parts of the statement are executed.

If you declare a variable in the initialization of a for loop, you can’t use that variable outside the loop. For instance, in Listing 6-2, you get an error message if you try putting `out.println(count)` after the end of the loop.

Anything that can be done with a for loop can also be done with a while loop. Choosing to use a for loop is a matter of style and convenience, not necessity.
The world premiere of “Al’s All Wet”

Listing 6-2 is very nice, but the program in that listing doesn’t do anything interesting. For a more eye-catching example, see Listing 6-3. In Listing 6-3, I make good on a promise I made in Chapter 5. The program in Listing 6-3 prints all the lyrics of the hit single, “Al’s All Wet.” (You can find the lyrics in Chapter 5.)

Listing 6-3: The Unabridged “Al’s All Wet” Song

```java
import static java.lang.System.out;

class AlsAllWet {
    public static void main(String args[]) {
        for (int verse = 1; verse <= 3; verse++) {
            out.print("Al's all wet. ");
            out.println("Oh, why is Al all wet? Oh.");
            out.print("Al's all wet 'cause ");
            out.println("he's standing in the rain.");
            out.println("Why is Al out in the rain?");

            switch (verse) {
                case 1:
                    out.println("That's because he has no brain.");
                    break;
                case 2:
                    out.println("That's because he is a pain.");
                    break;
                case 3:
                    out.println("'Cause this is the last refrain.");
                    break;
            }

            switch (verse) {
                case 3:
                    out.println("Last refrain, last refrain.");
                case 2:
                    out.println("He's a pain, he's a pain.");
                case 1:
                    out.println("Has no brain, has no brain.");
            }

            out.println("In the rain, in the rain.");
            out.println("Ohhhhhhh... ");
            out.println();
        }
    }
}
```
out.print("Al's all wet. ");
out.println("Oh, why is Al all wet? Oh.");
out.print("Al's all wet 'cause ");
out.println("he's standing in the rain.");
}
}

Listing 6-3 is nice because it combines many of the ideas from Chapters 5 and 6. In Listing 6-3, two switch statements are nested inside a for loop. One of the switch statements uses break statements; the other switch statement uses fall-through. As the value of the for loop’s counter variable (verse) goes from 1 to 2 and then to 3, all the cases in the switch statements are executed. When the program is near the end of its run and execution has dropped out of the for loop, the program’s last four statements print the song’s final verse.

When I boldly declare that a for statement is for counting, I’m stretching the truth just a bit. Java’s for statement is very versatile. You can use a for statement in situations that have nothing to do with counting. For instance, a statement with no update part, such as for(i=0; i<10;), just keeps on going. The looping ends when some action inside the loop assigns a big number to the variable i. You can even create a for statement with nothing inside the parentheses. The loop for( ; ; ) runs forever, which is good if the loop controls a serious piece of machinery. Usually, when you write a for statement, you’re counting how many times to repeat something. But, in truth, you can do just about any kind of repetition with a for statement.

Listing 6-3 uses break statements to jump out of a switch. But a break statement can also play a role inside a loop. To see an example, visit this book’s Web site.

---

Repeating Until You Get What You Want (Java do Statements)

"Fools rush in where angels fear to tread."

—Alexander Pope

Today, I want to be young and foolish (or, at the very least, foolish). Look back at Figure 6-2 and notice how Java’s while loop works. As execution enters a while loop, the computer checks to make sure that the loop’s condition is true. If the condition isn’t true, the statements inside the loop are never executed — not even once. In fact, you can easily cook up a while loop whose statements are never executed (although I can’t think of a reason why you would ever want to do it).
int twoPlusTwo = 2 + 2;

while (twoPlusTwo == 5) {
    out.println("Are you kidding?");
    out.println("2 + 2 doesn't equal 5");
    out.print("Everyone knows that");
    out.println(" 2 + 2 equals 3");
}

In spite of this silly twoPlusTwo example, the while statement turns out to be the most versatile of Java’s looping constructs. In particular, the while loop is good for situations in which you must look before you leap. For example: “While money is in my account, write a mortgage check every month.” When you first encounter this statement, if your account has a zero balance, you don’t want to write a mortgage check — not even one check.

But at times (not many), you want to leap before you look. Take, for instance, the situation in which you’re asking the user for a response. Maybe the user’s response makes sense, but maybe it doesn’t. If it doesn’t, you want to ask again. Maybe the user’s finger slipped, or perhaps the user didn’t understand the question.

Figure 6-5 shows some runs of a program to delete a file. Before deleting the file, the program asks the user whether making the deletion is okay. If the user answers y or n, the program proceeds according to the user’s wishes. But if the user enters any other character (any digit, uppercase letter, punctuation symbol, or whatever), the program asks the user for another response.

To write this program, you need a loop — a loop that repeatedly asks the user whether the file should be deleted. The loop keeps asking until the user gives a meaningful response. Now, the thing to notice is that the loop doesn’t need to check anything before asking the user the first time. Indeed, before the user gives the first response, the loop has nothing to check. The loop doesn’t start with “as long as such-and-such is true, then get a response from the user.” Instead, the loop just leaps ahead, gets a response from the user, and then checks the response to see if it made sense.
That’s why the program in Listing 6-4 has a do loop (also known as a do...while loop). With a do loop, the program jumps right in, takes action, and then checks a condition to see whether the result of the action makes sense. If the result makes sense, execution of the loop is done. If not, the program goes back to the top of the loop for another go-around.

Listing 6-4: To Delete, or Not to Delete

```java
import java.io.File;
import static java.lang.System.out;
import java.util.Scanner;

class DeleteEvidence {
    public static void main(String args[]) {
        File evidence = new File("c:\cookedBooks.txt");
        Scanner myScanner = new Scanner(System.in);
        char reply;
        do {
            out.print("Delete evidence? (y/n) ");
            reply = myScanner.next().charAt(0);
        } while (reply != 'y' && reply != 'n');
        if (reply == 'y') {
            out.println("Okay, here goes...");
            evidence.delete();
        } else {
            out.println("Sorry, buddy. Just asking.");
        }
    }
}
```

Figure 6-5 (shown previously) shows two runs of the code in Listing 6-4. The program accepts lowercase letters y and n, but not the uppercase letters Y and N. To make the program accept uppercase letters, change the conditions in the code as follows:

```java
do {
    out.print("Delete evidence? (y/n) ");
    reply = myScanner.next().charAt(0);
} while (reply != 'y' && reply != 'Y' && reply != 'n' && reply!='N');
if (reply == 'y' || reply == 'Y')
```

Figure 6-6 shows the flow of control in the loop of Listing 6-4. With a do loop, the situation in the twoPlusTwo program (shown earlier) can never happen. Because the do loop carries out its first action without testing a condition, every do loop is guaranteed to perform at least one iteration.
Reading a single character

In Listing 5-3, the user types a word on the keyboard. The myScanner.next method grabs the word, and places the word into a String variable named password. Everything works nicely because a String variable can store many characters at once and the next method can read many characters at once.

But in Listing 6-4, you’re not interested in reading several characters. You expect the user to type one letter — either y or n. So you don’t create a String variable to store the user’s response. Instead, create a char variable — a variable that stores just one symbol at a time.

The Java API doesn’t have a nextChar method. To read something suitable for storage in a char variable, you have to improvise. The code in Listing 6-4 reads an entire string with the next method, then grabs the string’s starting character with charAt(0). So if the user types the word yes, several things happen:

1. The next method gets yes from the keyboard.
2. The charAt method grabs the letter y from the string yes.
3. The letter y gets assigned to the variable reply.

A String variable can contain many characters or just one character. But a String variable that contains only one character isn’t the same as a char variable. No matter what you put in a String variable, String variables and char variables have to be treated differently.
File handling in Java

In Listing 6-4, the actual file-handling statements deserve some attention. These statements involve the use of classes, objects, and methods. Many of the meaty details about these things are in other chapters, like Chapters 7 and 9. Even so, I can’t do any harm by touching on some highlights right here.

So, you can find a class in the Java language API named java.io.File. The statement

```java
File evidence = new File("c:\\cookedBooks.txt");
```

creates a new object in the computer’s memory. This object, formed from the java.io.File class, describes everything that the program needs to know about the disk file c:\cookedBooks.txt. (In Java, when you want to indicate a backslash inside a double-quoted String literal, you use a double backslash instead.) From this point on in Listing 6-4, the variable evidence refers to the disk file c:\cookedBooks.txt.

After you’ve got all this java.io.File stuff in your head, the only thing left to know is that the evidence object, being an instance of the java.io.File class, has a delete method. (What can I say? It’s in the API documentation.) When you call evidence.delete, the computer gets rid of the file for you.

Variable declarations and blocks

A bunch of statements surrounded by curly braces form a block. If you declare a variable inside a block, you generally can’t use that variable outside the block. For instance, in Listing 6-4, you get an error message if you make the following change:

```java
do {
    out.print("Delete evidence? (y/n) ");
    char reply = myScanner.next().charAt(0);
} while (reply != 'y' && reply != 'n');
if (reply == 'y')
```

With the declaration char reply inside the loop’s curly braces, no use of the name reply makes sense anywhere outside the braces. When you try to compile this code, you get three error messages — two for the reply words in while (reply != 'y' && reply != 'n'), and a third for the if statement’s reply.
So in Listing 6-4, your hands are tied. The program’s first real use of the `reply` variable is inside the loop. But, to make that variable available after the loop, you have to declare `reply` before the loop. In this situation, you’re best off declaring the `reply` variable without initializing the variable. Very interesting!

To read more about variable initializations, see Chapter 4. To read more about blocks, see Chapter 5.

**Loops Made Painless**

I’ll never forget the first time I played *Clue*. We bought the board game during a family vacation in Niagara Falls. (Niagara Falls?) Cousin Alan and I sat in the hotel room playing the game for hours on end. I scribbled complicated assertions in my little detective’s notebook.

At one point, I bluffed by suggesting three cards that I had in my hand. Alan took the bait and made an accusation that was wrong on all three counts. Because he’d lost the game, and because I was being so smug about it, he beat the living daylights out of me. It was heaven. If I had the chance, I’d do it all over again.

**Don’t need no stinking counters**

The `for` loop in Listing 6-2 counts from 1 to 10. And its friend (the `for` loop in Listing 6-3) counts 1, 2, 3. This counting is very nice, but sometimes it’s not the most natural way to think about a problem. Take, for instance, the listing of all possible accusations in the board game *Clue*. The suspects aren’t numbered from 1 to 6, and neither are the rooms or weapons. You can number all these things, but why bother with numbering when the programming language provides a simpler solution?

Java’s *enhanced for loop* lets you cycle through groups of things without creating a counting variable. All you have to do is define the group. Listing 6-5 shows you what to do.

**Listing 6-5: “I Accuse . . .”**

```java
import static java.lang.System.out;

class Clue {
    enum Suspect {mustard, plum, green,
                   peacock, scarlet, white};
```
enum Room {ballroom, kitchen, diningRoom, lounge, hall, study, library, billiardRoom, conservatory};

denum Weapon {knife, candlestick, revolver, rope, leadPipe, wrench};

public static void main(String args[]) {
    for (Suspect mySuspect : Suspect.values()) {
        for (Room myRoom : Room.values()) {
            for (Weapon myWeapon : Weapon.values()) {
                out.print(mySuspect);
                out.print(" in the ");
                out.print(myRoom);
                out.print(" with a ");
                out.println(myWeapon);
            }
        }
    }
    Suspect killer = Suspect.peacock;
    Room sceneOfTheCrime = Room.study;
    Weapon murderWeapon = Weapon.leadPipe;
    
    out.println();
    out.print("I accuse ");
    out.print(killer);
    out.print(" in the ");
    out.print(sceneOfTheCrime);
    out.print(" with a ");
    out.println(murderWeapon);
    out.println(".");
}

The output of the code in Listing 6-5 has 324 lines, so I can’t show it all to you. But the first several lines appear in Figure 6-7. First, you see Colonel Mustard’s ballroom antics. Then you get Mustard’s kitchen tricks. Later in the run, when all of Mustard’s frolics are finished, you see the same possibilities for Professor Plum.

---

Figure 6-7: The code in Listing 6-5 starts running.
Listing 6-5 has a loop within a loop within a loop.

- The Room loop is inside of the Suspect loop. Not only do you loop through all the rooms, but you loop through all the rooms six times — once for each of the six suspects. If I count them up, that makes 54 visits to various rooms.

- The Weapon loop is inside of the Room loop. So every time you visit a room (and you visit a room 54 times), you go through all six of the hideous weapons.

Like the code in Listing 6-3, this section’s Clue program nests statements within other statements. In Listing 6-3, I nested switch statements inside a big for statement. But in the Clue program, I nest for statements inside of other for statements. It may look at bit tangled at first, but when you get used to it, nesting loop within loop is a really useful technique.

Grouping things together

Java provides lots of ways for you to group things together. In Chapter 11, you can group things into an array or a collection. In this chapter, you group things into an enum type. (Of course, you can’t group anything unless you can pronounce enum. The word enum is pronounced ee-noom, like the first two syllables of the word enumeration.)

Creating a complicated enum type isn’t easy, but to create a simple enum type, just write a bunch of words inside a pair of curly braces. Listing 6-5 has three enum types. The names of the enum types are Suspect, Room, and Weapon.

When you define an enum type, two important things happen:

- You create values.
  
  Just as 13 and 151 are int values, mustard and plum are Suspect values.

- You can create variables to refer to those values.

  After the for loop in Listing 6-5, I declare a variable named killer. Just as int numGuesses declares a numGuesses variable is of type int, and just as String myTitle declares variable myTitle to be of type String, so Suspect killer declares variable killer to be of type Suspect.

  I declare int numGuesses in Listing 6-1, and I declare String myTitle in Listing 4-6.
Being of type `Suspect` means that you can have values `mustard`, `plum`, `green`, and so on. So in Listing 6-5, I give the `killer` variable the value `peacock`. (At this point in the code, if I don’t type the longer dotted name `Suspect.peacock`, the Java compiler gets confused.)

In a similar way, I create variables `sceneOfTheCrime` and `murderWeapon` toward the end of Listing 6-5. Both of these variables have `enum` types, and both are given appropriate values (values like `Room.study` and `Weapon.leadPipe`).

In Listing 6-5, all the `enum` type declarations are outside of the `main` method. (For example, the line that begins with `enum Suspect` is before the start of the `main` method.) Java doesn’t allow you to put an `enum` type declaration inside a method. That’s because an `enum` type declaration is really a Java class in disguise. For more insight on `enum` types, see Chapter 9.

**Anatomy of an enhanced for loop**

The enhanced and un-enhanced `for` loops have a lot in common. Figure 6-8 illustrates the point.

In both kinds of loops, you define a variable. The loop in Listing 6-2 defines a variable named `count`. The loop in Listing 6-5 defines a variable named `mySuspect`.

In both listings, the statements inside the loop refer to the newly defined variable. The loop in Listing 6-2 has the statement

```java
out.print(count);
```
and the loop in Listing 6-5 has the statement

```java
out.print(mySuspect);
```

During successive iterations, the `print` in Listing 6-2 stands for `out.print(1)`, `out.print(2)`, and so on. During successive iterations, the `print` in Listing 6-5 stands for `out.print(mustard)`, `out.print(plum)`, and so on.

**In both kinds of loops, you declare the type of value that the variable can have.**

In Listing 6-2, the variable `count` must store an `int` value (–7, 0, 5, 15, and so on). In Listing 6-5, the variable `mySuspect` must refer to a `Suspect` value (mustard, plum, white, and so on).

In fact, this *declaring the type of value* rule applies everywhere in Java — not only in `for` loops. Every Java variable belongs to one type or another. In Listing 6-1, the line

```java
int numGuesses = 0;
```

declares that `numGuesses` must store an `int` value. The line goes on to say that, among all possible `int` values, the starting value for `numGuesses` is 0. Again in Listing 6-1, the line

```java
Scanner myScanner = new Scanner(System.in);
```

declares that `myScanner` must refer to a `Scanner` object. Among all such objects, the starting value for `myScanner` is an object that gets keystrokes from the keyboard (from `System.in`).

**In both kinds of loops, you specify a range of values.**

You specify the range of values that the variable takes on during the execution of the loop. In Listing 6-2, you narrow the `count` variable’s values to the numbers from 1 to 10. In Listing 6-5, you throw caution to the wind, and say that `mySuspect` gets to be every one of the items in `Suspect.values()`.

You can apply `values()` to the name of any `enum` type. In fact, to create an enhanced `for` loop with an `enum` type, you have to use something like `values()`. The expression `Suspect.values()` stands for all the items you list in the declaration of the `Suspect enum` type. So, in the loop of Listing 6-5, `mySuspect` becomes `mustard`, then `plum`, then `green`, and so on.

When you apply `values()` to the name of an `enum` type, you get an array of items belonging to that `enum` type. To read all about arrays, see Chapter 11.
Part III
Working with the Big Picture: Object-Oriented Programming

The 5th Wave By Rich Tennant

"We met on the Internet and I absolutely fell in loove with his syntax."
Have you read or heard anything about object-oriented programming? Sometimes, all the object-oriented programmers seem to belong to a little club. They have a secret handshake, a secret sign, and a promise not to reveal object-oriented programming concepts to any outsiders. Well, the secrecy is ending. In this part, I take all the mystery out of object-oriented programming. I introduce the concepts step by step and illustrate each concept with a Java program or two.
Chapter 7

Thinking in Terms of Classes and Objects

In This Chapter
► Thinking like a real object-oriented programmer
► Passing values to and from methods
► Hiding details in your object-oriented code

As a computer book author, I’ve been told this over and over again — I shouldn’t expect people to read sections and chapters in their logical order. People jump around, picking what they need and skipping what they don’t feel like reading. With that in mind, I realize that you may have skipped Chapter 1. If that’s the case, please don’t feel guilty. You can compensate in just sixty seconds by reading the following information from Chapter 1:

*Because Java is an object-oriented programming language, your primary goal is to describe classes and objects. A class is the idea behind a certain kind of thing. An object is a concrete instance of a class. The programmer defines a class, and from the class definition, the computer makes individual objects.*

Of course, you can certainly choose to skip over the 60-second summary paragraph. If that’s the case, you may want to recoup some of your losses. You can do that by reading the following two-word summary of Chapter 1:

*Classes; objects.*
Defining a Class (What It Means to Be an Account)

What distinguishes one bank account from another? If you ask a banker this question, you hear a long sales pitch. The banker describes interest rates, fees, penalties — the whole routine. Fortunately for you, I'm not interested in all that. Instead, I want to know how my account is different from your account. After all, my account is named Barry Burd, trading as Burd Brain Consulting, and your account is named Jane Q. Reader, trading as Budding Java Expert. My account has $24.02 in it. How about yours?

When you come right down to it, the differences between one account and another can be summarized as values of variables. Maybe there's a variable named balance. For me, the value of balance is 24.02. For you, the value of balance is 55.63. The question is, in writing a computer program to deal with accounts, how do I separate my balance variable from your balance variable?

The answer is to create two separate objects. Let one balance variable live inside one of the objects and let the other balance variable live inside the other object. While you're at it, put a name variable and an address variable in each of the objects. And there you have it. You've got two objects, and each object represents an account. More precisely, each object is an instance of the Account class. (See Figure 7-1.)

<table>
<thead>
<tr>
<th>An instance of the Account class</th>
<th>Another instance of the Account class</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: Barry</td>
<td>name: Jane</td>
</tr>
<tr>
<td>address: 222 Cyberspace Lane</td>
<td>address: 111 Consumer Street</td>
</tr>
<tr>
<td>balance: 24.02</td>
<td>balance: 55.63</td>
</tr>
</tbody>
</table>

So far, so good. But you still haven't solved the original problem. In your computer program, how do you refer to my balance variable, as opposed to your balance variable? Well, you have two objects sitting around, so maybe you have variables to refer to these two objects. Create one variable named
myAccount and another variable named yourAccount. The myAccount variable refers to my object (my instance of the Account class) with all the stuff that’s inside it. To refer to my balance, write

```java
myAccount.balance
```

To refer to my name, write

```java
myAccount.name
```

Then yourAccount.balance refers to the value in your object’s balance variable, and yourAccount.name refers to the value of your object’s name variable. To tell the computer how much I have in my account, you can write

```java
myAccount.balance = 24.02;
```

To display your name on the screen, you can write

```java
out.println(yourAccount.name);
```

These ideas come together in Listings 7-1 and 7-2.

**Listing 7-1: What It Means to Be an Account**

```java
class Account {
    String name;
    String address;
    double balance;
}
```

**Listing 7-2: Dealing with Account Objects**

```java
import static java.lang.System.out;

class UseAccount {
    public static void main(String args[]) {
        Account myAccount;
        Account yourAccount;

        myAccount = new Account();
        yourAccount = new Account();

        myAccount.name = "Barry Burd";
        myAccount.address = "222 Cyberspace Lane";
        myAccount.balance = 24.02;
    }
}
```

(continued)
Listing 7-2 (continued)

```
yourAccount.name = "Jane Q. Public";
yourAccount.address = "111 Consumer Street";
yourAccount.balance = 55.63;

out.print(myAccount.name);
out.print(" (");
out.print(myAccount.address);
out.print(") has \\
out.print(myAccount.balance);
out.println();

out.print(yourAccount.name);
out.print(" (");
out.print(yourAccount.address);
out.print(") has \\
out.print(yourAccount.balance);
```

Taken together, the two classes — Account and UseAccount — form one complete program. The Account class defines what it means to be an Account. The code for the Account class tells you that each of the Account class's instances has three variables — name, address, and balance. This is consistent with the information in Figure 7-1.

If you've been grappling with the material in Chapters 4 through 6, the code for class Account (Listing 7-1) may come as a big shock to you. Can you really define a complete Java class with only four lines of code (give or take a curly brace)? You certainly can. In fact, the Account class in Listing 7-1 is quite representative of what Java programmers think of when they think class. A class is a grouping together of existing things. In the Account class of Listing 7-1, those existing things are two String values and a double value.

The code in Listing 7-2 defines the UseAccount class. The code needs a main method, and every method has to be in one class or another. So put the main method in a class named UseAccount. This main method has variables of its own — yourAccount and myAccount.

**Declaring variables and creating objects**

In a way, the first two lines inside the main method of Listing 7-2 are misleading. Some people read Account yourAccount as if it's supposed to mean, “yourAccount is an Account,” or “The variable yourAccount refers to an
instance of the Account class.” That’s not really what this first line means. Instead, the line Account yourAccount means, “If and when I make the variable yourAccount refer to something, that something will be an instance of the Account class.” So, what’s the difference?

The difference is, simply declaring Account yourAccount doesn’t make the yourAccount variable refer to an object. All the declaration does is reserve the variable name yourAccount so that the name can eventually refer to an instance of the Account class. The creation of an actual object doesn’t come until later in the code, when the computer executes new Account().

Technically, when the computer executes new Account(), you’re creating an object by calling the Account class’s constructor. I have more to say about that in Chapter 9.

When the computer executes the assignment yourAccount = new Account(), the computer creates a new object (a new instance of the Account class) and makes the variable yourAccount refer to that new object. (It’s the equal sign that makes the variable refer to the new object.) The situation is illustrated in Figure 7-2.

To test the claim that I made in the last few paragraphs, I added an extra line to the code of Listing 7-1. I tried to print yourAccount.name after declaring yourAccount, but before calling new Account().
When I tried to compile the new code, I got this error message: variable yourAccount might not have been initialized. So that settles it. Before you do new Account(), you can’t print the name variable of an object; an object doesn’t exist.

When a variable has a reference type, simply declaring the variable isn’t enough. You don’t get an object until you call a constructor and use the keyword new.

For information about reference types, see Chapter 4.

**Initializing a variable**

In Chapter 4, I announce that you can initialize a primitive type variable as part of the variable’s declaration.

```java
int weightOfAPerson = 150;
```

You can do the same thing with reference type variables, such as myAccount and yourAccount in Listing 7-2. You can combine the first four lines in the listing’s main method into just two lines, like this:

```java
Account myAccount = new Account();
Account yourAccount = new Account();
```

If you combine lines this way, you automatically avoid the variable might not have been initialized error that I describe in the previous section. Sometimes you find a situation in which you can’t initialize a variable. But when you can initialize, it’s usually a plus.

**Using variables**

After you’ve bitten off and chewed the main method’s first four lines, the rest of the code in Listing 7-2 is sensible and straightforward. You have three lines that put values in the myAccount object’s variables, three lines that put values in the yourAccount object’s variables, and four lines that do some printing. The program’s output is shown in Figure 7-3.
Compiling and Running More Than One Class

Each program in Chapters 3 to 6 consists of a single class. That’s great for a book’s introductory chapters. But in real life, a typical program consists of hundreds or even thousands of classes. The program that spans Listings 7-1 and 7-2 consists of two classes. Sure, having two classes isn’t like having thousands of classes, but it’s a step in that direction.

In practice, most programmers put each class in a file of its own. When you create a program like the one in Listings 7-1 and 7-2, you create two files on your computer’s hard drive. So the code that comes from this book’s CD-ROM has two separate files — Account.java and UseAccount.java. (See Figure 7-4.)

To run the code, just do what you do to run any old single-file program.

1. Open the Chapter07 workspace.
2. Set Listings0701-02 as the active project.
3. Choose Build: Compile Project.
For details on compiling and running code that’s copied from the CD-ROM, see Chapter 2.

Creating a new program with two or more classes is also pretty easy. (All you have to do is flip back and forth a million times between this chapter and Chapter 3.)

1. **Follow Steps 1 through 7 in the typing your own code section of Chapter 3.**

   With these steps, you create a new project.

2. **Follow Steps 8 through 11 (also in the typing your own code section of Chapter 3) to create the first of two or more classes.**

   If you’re experimenting with the code in Listings 7-1 and 7-2, this first class is named `Account`.

3. **Follow Steps 8 through 11 again to create another class.**

   If you’re experimenting with the code in Listings 7-1 and 7-2, this second class is named `UseAccount`.

   Repeat Steps 8 through 11 once for each of the classes in your Java program.

4. **Follow Steps 12 through 15 in that same section of Chapter 3.**

   When you do, JCreator compiles and runs your program.

When you work with several classes at once, you can easily get the following unfriendly message: `NoSuchMethodError: main`. You see this when you try to execute a class that has no `main` method. For example, the `Account` class in Listing 7-1 has no `main` method. If the `Account` class’s code is the frontmost code in JCreator’s Editor pane, and you choose Build ➪ Execute File (instead of Build ➪ Execute Project) from JCreator’s main menu, you get the dreaded `NoSuchMethodError`. To fix this, always make sure that your project has a class with a `main` method, and always choose Build ➪ Execute Project to run your code.

### Defining a Method within a Class (Displaying an Account)

Imagine a table containing the information about two accounts. (If you have trouble imagining such a thing, just look at Table 7-1.)
Table 7-1 Without Object-Oriented Programming

<table>
<thead>
<tr>
<th>Name</th>
<th>Address</th>
<th>Balance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Barry Burd</td>
<td>222 Cyberspace Lane</td>
<td>24.02</td>
</tr>
<tr>
<td>Jane Q. Public</td>
<td>111 Consumer Street</td>
<td>55.63</td>
</tr>
</tbody>
</table>

In Table 7-1, each account has three things — a name, an address, and a balance. That’s the way things were done before object-oriented programming came along. But object-oriented programming involved a big shift in thinking. With object-oriented programming, each account can have a name, an address, a balance, and a way of being displayed.

In object-oriented programming, each object has its own built-in functionality. An account knows how to display itself. A string can tell you whether it has the same characters inside it as another string. A PrintStream instance, such as System.out, knows how to do println. In object-oriented programming, each object has its own methods. These methods are little subprograms that you can call to have an object do things to (or for) itself.

And why is this a good idea? It’s good because you’re making pieces of data take responsibility for themselves. With object-oriented programming, all the functionality that’s associated with an account is collected inside the code for the Account class. Everything you have to know about a string is located in the file String.java. Anything having to do with year numbers (whether they have two or four digits, for instance) is handled right inside the Year class. So, if anybody has problems with your Account class or your Year class, he or she knows just where to look for all the code. That’s great!

So imagine an enhanced account table. In this new table, each object has built-in functionality. Each account knows how to display itself on the screen. Each row of the table has its own copy of a display method. Of course, you don’t need much imagination to picture this table. I just happen to have a table you can look at. It’s Table 7-2.

Table 7-2 The Object-Oriented Way

<table>
<thead>
<tr>
<th>Name</th>
<th>Address</th>
<th>Balance</th>
<th>Display</th>
</tr>
</thead>
<tbody>
<tr>
<td>Barry Burd</td>
<td>222 Cyberspace Lane</td>
<td>24.02</td>
<td>out.print....</td>
</tr>
<tr>
<td>Jane Q. Public</td>
<td>111 Consumer Street</td>
<td>55.63</td>
<td>out.print....</td>
</tr>
</tbody>
</table>
An account that displays itself

In Table 7-2, each account object has four things — a name, an address, a balance, and a way of displaying itself on the screen. After you make the jump to object-oriented thinking, you'll never turn back. A program that implements the ideas in Table 7-2 is shown in Listings 7-3 and 7-4.

Listing 7-3: An Account Displays Itself

```java
import static java.lang.System.out;

class Account {
    String name;
    String address;
    double balance;

    void display() {
        out.print(name);
        out.print(" (");
        out.print(address);
        out.print(") has ");
        out.print(balance);
    }
}
```

Listing 7-4: Using the Improved Account Class

```java
class UseAccount {
    public static void main(String args[]) {
        Account myAccount = new Account();
        Account yourAccount = new Account();

        myAccount.name = "Barry Burd";
        myAccount.address = "222 Cyberspace Lane";
        myAccount.balance = 24.02;

        yourAccount.name = "Jane Q. Public";
        yourAccount.address = "111 Consumer Street";
        yourAccount.balance = 55.63;

        myAccount.display();
        System.out.println();
        yourAccount.display();
    }
}
```
A run of the code in Listings 7-3 and 7-4 looks just like a run for Listings 7-1 and 7-2. You can see the action in Figure 7-3.

In Listing 7-3, the `Account` class has four things in it — a name, an address, a balance, and a display method. These things match up with the four columns in Table 7-2. So each instance of the `Account` class has a name, an address, a balance, and a way of displaying itself. The way you call these things is nice and uniform. To refer to the name stored in `myAccount`, you write

```java
myAccount.name
```

To get `myAccount` to display itself on the screen, you write

```java
myAccount.display()
```

The only difference is the parentheses.

When you call a method, you put parentheses after the method’s name.

---

**The display method’s header**

Look again at Listings 7-3 and 7-4. A call to the `display` method is inside the `UseAccount` class’s `main` method. But the declaration of the `display` method is up in the `Account` class. The declaration has a header and a body. (See Chapter 3.) The header has two words and some parentheses:

- **The word `void` tells the computer that when the `display` method is called, the `display` method doesn’t return anything to the place that called it.** To see a method that does return something to the place that called it, see the next section.

- **The word `display` is the method’s name.** Every method must have a name. Otherwise, you don’t have a way to call the method.

- **The parentheses contain all the things you’re going to pass to the method when you call it.** When you call a method, you can pass information to that method on the fly. The `display` method in Listing 7-3 looks strange because the parentheses in the method’s header have nothing inside them. This nothingness indicates that no information is passed to the `display` method when you call it. For a meatier example, see the next section.
Sending Values to and from Methods (Calculating Interest)

Think about sending someone to the supermarket to buy bread. When you do this, you say, “Go to the supermarket and buy some bread.” (Try it at home. You’ll have a fresh loaf of bread in no time at all!) Of course, some other time you send that same person to the supermarket to buy bananas. You say, “Go to the supermarket and buy some bananas.” And what’s the point of all this? Well, you have a method, and you have some on-the-fly information that you pass to the method when you call it. The method is named `goToTheSupermarketAndBuySome`. The on-the-fly information is either `bread` or `bananas`, depending on your culinary needs. In Java, the method calls would look like this:

```
goToTheSupermarketAndBuySome(bread);
goToTheSupermarketAndBuySome(bananas);
```

The things in parentheses are called parameters or parameter lists. With parameters, your methods become much more versatile. Instead of getting the same thing each time, you can send somebody to the supermarket to buy bread one time, bananas another time, and birdseed the third time. When you call your `goToTheSupermarketAndBuySome` method, you decide right there and then what you’re going to ask your pal to buy.

And what happens when your friend returns from the supermarket? “Here’s the bread you asked me to buy,” says your friend. As a result of carrying out your wishes, your friend returns something to you. You make a method call, and the method returns information (or a loaf of bread).

The thing returned to you is called the method’s return value. The general type of thing that was returned to you is called the method’s return type. These concepts are made more concrete in Listings 7-5 and 7-6.

Listing 7-5: An Account that Calculates Its Own Interest

```java
import static java.lang.System.out;

class Account {
    String name;
    String address;
    double balance;

    void display() {
        out.print(name);
        out.print(" (");
        out.print(address);
    }
}
```
out.print("\n has ");
out.print(balance);
}

double getInterest(double percentageRate) {
    return balance * percentageRate / 100.00;
}

Listing 7-6: Calculating Interest

import static java.lang.System.out;
class UseAccount {
    public static void main(String args[]) {
        Account myAccount = new Account();
        Account yourAccount = new Account();

        myAccount.name = "Barry Burd";
        myAccount.address = "222 Cyberspace Lane";
        myAccount.balance = 24.02;

        yourAccount.name = "Jane Q. Public";
        yourAccount.address = "111 Consumer Street";
        yourAccount.balance = 55.63;

        myAccount.display();
        out.print(" plus ");
        out.print(myAccount.getInterest(5.00));
        out.println(" interest ");

        yourAccount.display();
        double yourInterestRate = 7.00;
        out.print(" plus ");
        double yourInterestAmount = 
            yourAccount.getInterest(yourInterestRate);
        out.println(yourInterestAmount);
        out.println(" interest ");
    }
}

The output of the code in Listings 7-5 and 7-6 is shown in Figure 7-5. In Listing 7-5, the Account class has a getInterest method. This getInterest method is called twice from the main method in Listing 7-6. The actual account balances and interest rates are different each time.
In the first call, the balance is 24.02, and the interest rate is 5.00. The first call, `myAccount.getInterest(5.00)`, refers to the `myAccount` object and all the variables inside it. (See Figure 7-6.) When this call is made, the expression `balance * percentageRate / 100.00` stands for `24.02 * 5.00 / 100.00`.

In the second call, the balance is 55.63, and the interest rate is 7.00. In the main method, just before this second call is made, the variable `yourInterestRate` is assigned the value 7.00. The call itself, `yourAccount.getInterest(yourInterestRate)`, refers to the `yourAccount` object and all the variables inside it. (Again, see Figure 7-6.) So, when the call is made, the expression `balance * percentageRate / 100.00` stands for `55.63 * 7.00 / 100.00`.

An instance of the `Account` class

<table>
<thead>
<tr>
<th>name</th>
<th>Barry</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>222 Cyberspace Lane</td>
</tr>
<tr>
<td>balance</td>
<td>24.02</td>
</tr>
</tbody>
</table>

Another instance of the `Account` class

<table>
<thead>
<tr>
<th>name</th>
<th>Jane</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>111 Consumer Street</td>
</tr>
<tr>
<td>balance</td>
<td>55.63</td>
</tr>
</tbody>
</table>

By the way, the main method in Listing 7-3 contains two calls to `getInterest`. One call has the literal 5.00 in its parameter list; the other call has the variable `yourInterestRate` in its parameter list. Why does one call use a literal and the other call use a variable? No reason. I just wanted to show you that you can do it either way.
Passing a value to a method

Take a look at the `getInterest` method's header. (As you read the explanation in the next few bullets, you can follow some of the ideas visually with the diagram in Figure 7-7.)

The word `double` tells the computer that when the `getInterest` method is called, the `getInterest` method returns a double value back to the place that called it. The statement in the `getInterest` method's body confirms this. The statement says `return balance * percentageRate / 100.00;` and the expression `balance * percentageRate / 100.00` has type `double`. (That's because all the things in the expression — `balance`, `percentageRate`, and `100.00` — have type `double`.)

When the `getInterest` method is called, the return statement calculates `balance * percentageRate / 100.00` and hands the calculation's result back to the code that called the method.

The word `getInterest` is the method's name. That's the name you use to call the method when you're writing the code for the `UseAccount` class.

The parentheses contain all the things that you're going to pass to the method when you call it. When you call a method, you can pass information to that method on the fly. This information is the method's parameter list. The `getInterest` method's header says that the `getInterest` method takes one piece of information and that piece of information must be of type `double`.

```java
double getInterest(double percentageRate) {
    return balance * percentageRate / 100.00;
}
```
Sure enough, if you look at the first call to `getInterest` (down in the `useAccount` class’s main method), that call has the number 5.00 in it. And 5.00 is a double literal. When I call `getInterest`, I’m giving the method a value of type double.

If you don’t remember what a literal is, see Chapter 4.

The same story holds true for the second call to `getInterest`. Down near the bottom of Listing 7-6, I call `getInterest` and feed the variable `yourInterestRate` to the method in its parameter list. Luckily for me, I declared `yourInterestRate` to be of type double just a few lines before that.

When you run the code in Listings 7-5 and 7-6, the flow of action isn’t from top to bottom. The action goes from `main` to `getInterest`, then back to `main`, then back to `getInterest`, and finally back to `main` again. The whole business is shown in Figure 7-8.

Returning a value from the `getInterest` method

When the `getInterest` method is called, the method executes the one statement that’s in the method’s body: a `return` statement. The `return` statement computes the value of `balance * percentageRate / 100.00`. If `balance` happens to be 24.02, and `percentageRate` is 5.00, the value of the expression is 1.201 — around $1.20. (Because the computer works exclusively with 0s and 1s, the computer gets this number wrong by an ever so tiny amount. The computer gets 1.2009999999999998. That’s just something that humans have to live with.)

Anyway, after this value is calculated, the computer executes the return, which sends the value back to the place in `main` where `getInterest` was called. At that point in the process, the entire method call — `myAccount.getInterest(5.00)` — takes on the value 1.2009999999999998. The call itself is inside a `println`:

```java
out.println(myAccount.getInterest(5.00));
```

So the `println` ends up with the following meaning:

```java
out.println(1.2009999999999998);
```

The whole process, in which a value is passed back to the method call, is illustrated in Figure 7-9.
class Account {
    Yada, yada, yada...

double getInterest(double percentageRate) {
    return balance * percentageRate / 100.00;
}
}

class UseAccount {

    public static void main(String args[]) {
        Account myAccount = new Account();
        Account yourAccount = new Account();

        myAccount.name = "Barry Burd";
        myAccount.address = "222 Cyberspace Lane";
        myAccount.balance = 24.02;

        yourAccount.name = "Jane Q. Public";
        yourAccount.address = "111 Consumer Street";
        yourAccount.balance = 55.63;

        myAccount.display();
        out.print(" plus ");
        out.print(
            myAccount.getInterest(5.00)
        );
        out.println(" interest ");

        yourAccount.display();
        double yourInterestRate = 7.00;
        out.print(" plus ");
        double yourInterestAmount = 
            yourAccount.getInterest(yourInterestRate);
        out.print(yourInterestAmount);
        out.println(" interest ");
    }
}
If a method returns anything, a call to the method is an expression with a value. That value can be printed, assigned to a variable, added to something else, or whatever. Anything you can do with any other kind of value, you can do with a method call.

**Making numbers look good**

Looking back at Figure 7-5, you may be concerned that the interest on my account is only $1.2009999999999998. Seemingly, the bank is cheating me out of 200-trillionths of a cent. I should go straight there and demand my fair interest. Maybe you and I should go together. We’ll kick up some fur at that old bank and bust this scam right open. If my guess is correct, this is part of a big *salami scam*. In a salami scam, someone shaves little slices off millions of accounts. People don’t notice their tiny little losses, but the person doing the shaving collects enough for a quick escape to Barbados (or for a whole truck-load of salami).

But, wait a minute! Nothing is motivating you to come with me to the bank. Checking back at Figure 7-5, I see that you’re way ahead of the game. According to my calculations, the program overpays you by 300-trillionths of a cent. Between the two of us, we’re ahead by a hundred-trillionth of a cent. What gives?

Well, because computers use 0s (zeros) and 1s and don’t have an infinite amount of space to do calculations, inaccuracies like the ones shown in Figure 7-5 are inevitable. The best that you can do is display numbers in a more sensible fashion. You can round the numbers and display only two digits beyond the decimal point, and some handy tools from Java’s API (Application Programming Interface) can help. The code is shown in Listing 7-7, and the pleasant result is displayed in Figure 7-10.
Listing 7-7: Making Your Numbers Look Right

import static java.lang.System.out;

class UseAccount {
    public static void main(String args[]) {
        Account myAccount = new Account();
        Account yourAccount = new Account();

        myAccount.balance = 24.02;
        yourAccount.balance = 55.63;

        double myInterest = myAccount.getInterest(5.00);
        double yourInterest = yourAccount.getInterest(7.00);

        out.printf("$%4.2f\n", myInterest);
        out.printf("$%5.2f\n", myInterest);
        out.printf("$%.2f\n", myInterest);
        out.printf("$%3.2f\n", myInterest);
        out.printf("$%.2f $%.2f", myInterest, yourInterest);
    }
}
Display a dollar sign.
Use appropriately many places to display a number and put two of these places to the right of the decimal point.
Go to a new line.

Figure 7-11: Using a format string.

"$%.2f\n"

What the computer displays:

$1.20

"a number" is the second parameter (the value of `myInterest`)

Figure 7-13: Displaying a value without specifying the exact number of places.

"$%.2f\n"

What the computer displays:

$1.20

Figure 7-12: Adding extra places to display a value.

"$%.5.2f\n"

What the computer displays:

$1.20

Because `myInterest` takes only four places, display `myInterest` with an extra blank space.
For more examples using the `printf` method and its format strings, see Chapters 8 and 9. For a complete list of options associated with the `printf` method’s format string, see the `java.util.Formatter` page of Java’s API documentation.

The format string in a `printf` call doesn’t change the way a number is stored internally for calculations. All the format string does is create a nice-looking bunch of digit characters that can be displayed on your screen.
Hiding Details with Accessor Methods (Why You Shouldn’t Micromanage a Bank Teller)

Put down this book and put on your hat. You’ve been such a loyal reader that I’m taking you out to lunch!

I’ve got just one problem. I’m a bit short on cash. Would you mind if, on the way to lunch, we stopped at an automatic teller machine and picked up a few bucks? Also, we have to use your account. My account is a little low.

Fortunately, the teller machine is easy to use. Just step right up and enter your PIN. After entering your PIN, the machine asks which of several variable names you want to use for your current balance. You have a choice of balance324, myBal, currentBalance, b$, BALANCE, asj999, or conStanTinple. Having selected a variable name, you’re ready to select a memory location for the variable’s value. You can select any number between 022FFF and 0555AA. (Those numbers are in hexadecimal format.) After you’ve configured the teller machine’s software, you can easily get your cash. You did bring a screwdriver, didn’t you?

Good programming

When it comes to good computer programming practice, one word stands out above all others — simplicity. When you’re writing complicated code, the last thing you want is to deal with somebody else’s misnamed variables; convoluted solutions to problems; or clever, last-minute kludges. You want a clean interface that makes you solve your own problems and no one else’s.

In the automatic teller machine scenario that I describe earlier, the big problem is that the machine’s design forces you to worry about other people’s concerns. When you should be thinking about getting money for lunch, you’re thinking instead about variables and storage locations. Sure, someone has to work out the teller machine’s engineering problems. But the banking customer isn’t the person to solve these problems.

This section is about safety, not security. Safe code keeps you from making accidental programming errors. Secure code (a completely different story) keeps malicious hackers from doing intentional damage.
So this means that everything connected with every aspect of a computer program has to be simple. Right? Well, no. That’s not right. Sometimes, to make things simple in the long run, you have to do lots of preparatory work up front. The people who built the automated teller machine worked hard to make sure that the machine is consumer-proof. The machine’s interface, with its screen messages and buttons, makes the machine a very complicated, but carefully designed, device.

The point is that making things look simple takes some planning. In the case of object-oriented programming, one of the ways to make things look simple is to keep code outside a class from directly using variables defined inside the class. Take a peek at the code in Listing 7-1. You’re working at a company that has just spent $10 million for the code in the *Account* class. (That’s more than a million and a half per line!) Now your job is to write the *UseAccount* class. You would like to write

```java
myAccount.name = "Barry Burd";
```

but doing so would be getting you too far inside the guts of the *Account* class. After all, people who use an automatic teller machine aren’t allowed to program the machine’s variables. They can’t use the machine’s keypad to type the statement

```java
balanceOnAccount29872865457 = balanceOnAccount29872865457 + 1000000.00;
```

Instead, they push buttons that do the job in an orderly manner. That’s how a programmer achieves safety and simplicity.

So, to keep things nice and orderly, you need to change the *Account* class from Listing 7-1 by outlawing statements such as the following:

```java
myAccount.name = "Barry Burd";
```

and

```java
out.print(yourAccount.balance);
```

But, of course, this poses a problem. You’re the person who’s writing the code for the *UseAccount* class. If you can’t write *myAccount.name* or *yourAccount.balance*, how are you going to accomplish anything at all? The answer lies in things called *accessor methods*. These methods are demonstrated in Listings 7-8 and 7-9.
Listing 7-8: Hide Those Variables

class Account {
    private String name;
    private String address;
    private double balance;

    public void setName(String n) {
        name = n;
    }

    public String getName() {
        return name;
    }

    public void setAddress(String a) {
        address = a;
    }

    public String getAddress() {
        return address;
    }

    public void setBalance(double b) {
        balance = b;
    }

    public double getBalance() {
        return balance;
    }
}

Listing 7-9: Calling Accessor Methods

import static java.lang.System.out;

class UseAccount {

    public static void main(String args[]) {
        Account myAccount = new Account();
        Account yourAccount = new Account();

        myAccount.setName("Barry Burd");
        myAccount.setAddress("222 Cyberspace Lane");
        myAccount.setBalance(24.02);

        yourAccount.setName("Jane Q. Public");
        yourAccount.setAddress("111 Consumer Street");
        yourAccount.setBalance(55.63);
    }
}
A run of the code in Listings 7-8 and 7-9 looks no different from a run of Listings 7-1 and 7-2. Either program's run is shown in Figure 7-3. The big difference is that in Listing 7-8, the Account class enforces the carefully controlled use of its internal variables.

Public lives and private dreams: Making a variable name inaccessible

Notice the addition of the word private in front of each of the Account class's variable declarations. The word private is a Java keyword. When a variable is declared to be private, no code outside of the class can make direct reference to that variable. So if you put myAccount.name="Barry Burd" in the UseAccount class of Listing 7-9, you get the error message name has private access in Account.

Instead of referencing myAccount.name, the UseAccount programmer must call method myAccount.setName or method myAccount.getName. These methods, setName and getName, are called accessor methods, because they provide access to the Account class's name variable. (Actually, the term accessor method isn't formally a part of the Java programming language. It's just the term that people use for methods that do this sort of thing.) To zoom in even more, setName is called a setter method, and getName is called a getter method. (I bet you won’t forget that terminology!)

Another commonly used term for an accessor method is a bean method. The phrase bean method comes from the world of JavaBeans — a way of plugging Java programs into existing graphical user interface (GUI) environments. Because JavaBeans relies heavily on accessor methods, many people associate accessor methods with the JavaBeans specification.
With the Pro version of JCreator, you don’t have to type your own accessor methods. First you type a variable declaration like `private String name`. Then, in JCreator Pro’s menu bar, you choose Tools➪Insert Bean Methods. After you approve the defaults in a small dialog box, JCreator creates accessor methods and adds them to your code.

Notice that all the setter and getter methods in Listing 7-8 are declared to be public. This ensures that anyone from anywhere can call these two methods. The idea here is that manipulating the actual variables from outside the `Account` code is impossible, but you can easily reach the approved setter and getter methods for using those variables.

To read more about the `public` and `private` keywords, see Appendix B and Chapter 15. (Chapter 15 is on the CD-ROM.)

Think again about the automatic teller machine. Someone using the ATM can’t type a command that directly changes the value in his or her account’s balance variable, but the procedure for depositing a million-dollar check is easy to follow. The people who build the teller machines know that if the check depositing procedure is complicated, plenty of customers will mess it up royally. So that’s the story — make impossible anything that people shouldn’t do and make sure that the tasks people should be doing are easy.

Nothing about having setter and getter methods is sacred. You don’t have to write any setter and getter methods that you’re not going to use. For instance, in Listing 7-8, I can omit the declaration of method `getAddress`, and everything still works. The only problem if I do this is that anyone else who wants to use my `Account` class and retrieve the address of an existing account is up a creek.

When you create a method to set the value in a `balance` variable, you don’t have to name your method `setBalance`. You can name it `tunaFish`, or whatever you like. The trouble is that the `setVariableName` convention (with lowercase letters in `set` and an uppercase letter to start the `VariableName` part) is an established stylistic convention in the world of Java programming. If you don’t follow the convention, you confuse the kumquats out of other Java programmers. If your integrated development environment has drag-and-drop GUI design capability, you may temporarily lose that capability. (For a word about drag-and-drop GUI design, see Chapter 2.)

When you call a setter method, you feed it a value of the type that’s being set. That’s why, in Listing 7-9, you call `yourAccount.setBalance(55.63)` with a parameter of type `double`. In contrast, when you call a getter method, you usually don’t feed any values to the method. That’s why, in Listing 7-9, you call `yourAccount.getBalance()` with an empty parameter list.
Occasionally, you may want to get and set a value with a single statement. To add a dollar to your account’s existing balance, you write `yourAccount.setBalance(yourAccount.getBalance() + 1.00)`.

**Enforcing rules with accessor methods**

Go back to Listing 7-8 and take a quick look at the `setName` method. Imagine putting the method’s assignment statement inside an `if` statement.

```java
if (!n.equals("")
    name=n;
```

Now, if the programmer in charge of the `UseAccount` class writes `myAccount.setName("")`, the call to `setName` doesn’t have any effect. Furthermore, because the `name` variable is private, the following statement is illegal in the `UseAccount` class:

```java
myAccount.name="";
```

Of course, a call such as `myAccount.setName("Joe Schmoe")` still works because "Joe Schmoe" doesn’t equal the empty string "".

That’s cool. With a private variable and an accessor method, you can prevent someone from assigning the empty string to an account’s `name` variable. With more elaborate `if` statements, you can enforce any rules you want.
Once upon a time, there was a beautiful princess. When the princess turned 25 (the optimal age for strength, good looks, and fine moral character), her kind father brought her a gift in a lovely golden box. Anxious to know what was in the box, the princess ripped off the golden wrapping paper.

When the box was finally opened, the princess was thrilled. To her surprise, her father had given her what she had always wanted—a computer program that always ran correctly. The program did everything the princess wanted and did it all exactly the way she wanted it to be done. The princess was happy, and so was her kind, old father.

As time went on, the computer program never failed. For years on end, the princess changed her needs, expected more out of life, made increasing demands, expanded her career, reached for more and more fulfillment, juggled the desires of her husband and her kids, stretched the budget, and sought peace within her soul. Through all this, the program remained her steady, faithful companion.

As the princess grew old, the program became old along with her. One evening, as she sat by the fireside, she posed a daunting question to the program. “How do you do it?” she asked. “How do you manage to keep giving the right answers, time after time, year after year?”
“Clean living,” replied the program. “I swim twenty apps each day, I take C++ to Word off viruses, I avoid logarithmic algorithms, I link Java in moderation, I say GNU to bugs, I don’t smoke to backup, and I never byte off more than I can queue.”

Needless to say, the princess was stunned.

Defining a Class (What It Means to Be an Employee)

Wouldn’t it be nice if every piece of software did just what you wanted it to do? In an ideal world, you could just buy a program, make it work right away, plug it seamlessly into new situations, and update it easily whenever your needs change. Unfortunately, software of this kind doesn’t exist. (Nothing of this kind exists.) The truth is, no matter what you want to do, you can find software that does some of it, but not all of it.

This is one of the reasons why object-oriented programming has been so successful. For years, companies were buying prewritten code only to discover that the code didn’t do what they wanted it to do. So what did the companies do about it? They started messing with the code. Their programmers dug deep into the program files, changed variable names, moved subprograms around, reworked formulas, and generally made the code worse. The reality was that if a program didn’t already do what you wanted it to do (even if it did something ever so close to what you wanted), you could never improve the situation by mucking around inside the code. The best option was always to chuck the whole program (expensive as that was) and start all over again. What a sad state of affairs!

With object-oriented programming, a big change has come about. At its heart, an object-oriented program is made to be modified. With correctly written software, you can take advantage of features that are already built-in, add new features of your own, and override features that don’t suit your needs. And the best part is that the changes you make are clean. No clawing and digging into other people’s brittle program code. Instead, you make nice, orderly additions and modifications without touching the existing code’s internal logic. It’s the ideal solution.

The last word on employees

When you write an object-oriented program, you start by thinking about the data. You’re writing about accounts. So what’s an account? You’re writing code to handle button clicks. So what’s a button? You’re writing a program to send payroll checks to employees. What’s an employee?
In this chapter’s first example, an employee is someone with a name and a job title. Sure, employees have other characteristics, but for now I stick to the basics. The code in Listing 8-1 defines what it means to be an employee.

Listing 8-1: What Is an Employee?

```java
import static java.lang.System.out;

class Employee {
    private String name;
    private String jobTitle;

    public void setName(String nameIn) {
        name = nameIn;
    }

    public String getName() {
        return name;
    }

    public void setJobTitle(String jobTitleIn) {
        jobTitle = jobTitleIn;
    }

    public String getJobTitle() {
        return jobTitle;
    }

    public void cutCheck(double amountPaid) {
        out.printf("Pay to the order of %s ", name);
        out.printf("(%s) ***$", jobTitle);
        out.printf("%,.2f\n", amountPaid);
    }
}
```

According to Listing 8-1, each employee has seven features. Two of these features are fairly simple. Each employee has a name and a job title.

And what else does an employee have? Each employee has four methods to handle the values of the employee’s name and job title. These methods are `setName`, `getName`, `setJobTitle`, and `getJobTitle`. Methods like these (accessor methods) are explained in Chapter 7.

On top of all that, each employee has a `cutCheck` method. The idea is that the method that writes payroll checks has to belong to one class or another. Because most of the information in the payroll check is customized for a particular employee, you may as well put the `cutCheck` method inside the `Employee` class.
For details about the printf calls in the cutCheck method, see the section entitled “Cutting a check,” later in this chapter.

**Putting your class to good use**

The Employee class in Listing 8-1 has no main method, so there’s no starting point for executing code. To fix this deficiency, the programmer must write a separate program with a main method and use that program to create Employee instances. (To find out how to compile two programs separately, see Chapter 7.) Listing 8-2 shows a class with a main method — one that puts the code in Listing 8-1 to the test.

### Listing 8-2: Writing Payroll Checks

```java
import java.util.Scanner;
import java.io.File;
import java.io.IOException;

class DoPayroll {
    public static void main(String args[]) throws IOException {
        Scanner diskScanner =
            new Scanner(new File("EmployeeInfo.txt"));

        for (int empNum = 1; empNum <= 3; empNum++) {
            payOneEmployee(diskScanner);
        }
    }

    static void payOneEmployee(Scanner aScanner) {
        Employee anEmployee = new Employee();

        anEmployee.setName(aScanner.nextLine());
        anEmployee.setJobTitle(aScanner.nextLine());
        anEmployee.cutCheck(aScanner.nextDouble());
        aScanner.nextLine();
    }
}
```

The DoPayroll class in Listing 8-2 has two methods. One of the methods, main, calls the other method, payOneEmployee, three times. Each time around, the payOneEmployee method gets stuff from the EmployeeInfo.txt file and feeds this stuff to the Employee class’s methods.
Here's how the variable name `anEmployee` is reused and recycled:

- The first time that `payOneEmployee` is called, the statement `anEmployee = new Employee()` makes `anEmployee` refer to a new object.
- The second time that `payOneEmployee` is called, the computer executes the same statement again. This creates a new incarnation of the `anEmployee` variable that refers to a brand-new object.
- The third time around, all the same stuff happens again. A new `anEmployee` variable ends up referring to a third object.

The whole story is pictured in Figure 8-1.

![Figure 8-1: Three calls to the payOneEmployee method.](image)

**Cutting a check**

Listing 8-1 has three `printf` calls. Each `printf` call has a format string (like `"(%s) ***$"`) and a variable (like `jobTitle`). Each format string has a placeholder (like `%s`) that determines where and how the variable’s value is displayed.

For example, in the second `printf` call, the format string has a `%s` placeholder. This `%s` holds a place for the `jobTitle` variable’s value. According to Java’s rules, the notation `%s` always holds a place for a string and, sure enough, the variable `jobTitle` is declared to be of type `String` in Listing 8-1. Parentheses and some other characters surround the `%s` placeholder, so parentheses surround each job title in the program’s output. (See Figure 8-2.)
Back in Listing 8-1, notice the comma inside the %,.2f placeholder. The comma tells the program to use grouping separators. That's why, in Figure 8-2, you see $5,000.00, $7,000.00, and $10,000.00 instead of $5000.00, $7000.00, and $10000.00.

Grouping separators vary from one country to another. For instance, in France, to write the number one thousand (mille), you write 1 000,00. Java can Frenchify your number automatically with a statement like `out.print(new java.util.Formatter().format(java.util.Locale.FRANCE, "%,.2f", 1000.00))`. For details, see the API (Application Programming Interface) documentation for Java's Formatter and Locale classes.

### Working with Disk Files
(A Brief Detour)

In previous chapters, programs read characters from the computer's keyboard. But the code in Listing 8-2 reads characters from a specific file. The file (named EmployeeInfo.txt) lives on your computer's hard drive.

This EmployeeInfo.txt file is like a word processing document. The file can contain letters, digits, and other characters. But unlike a word processing document, the EmployeeInfo.txt file contains no formatting — no italics, no bold, no font sizes, nothing of that kind.

The EmployeeInfo.txt file contains only ordinary characters — the kinds of keystrokes that you type while you play a guessing game from Chapters 5 or 6. Of course, getting guesses from a user's keyboard and reading employee data from a disk file aren't exactly the same. In a guessing game, the program displays prompts, such as Enter an int from 1 to 10. The game program conducts a back-and-forth dialogue with the person sitting at the keyboard. In contrast, Listing 8-2 has no dialogue. This DoPayroll program reads characters from a hard drive and doesn't prompt or interact with anyone.
Most of this chapter is about code reuse. But Listing 8-2 stumbles upon an important idea — an idea that's not directly related to code reuse. Unlike the examples in previous chapters, Listing 8-2 reads data from a stored disk file. So in this section, I take a short side trip to explore disk files.

**Storing data in a file**

The code in Listing 8-2 doesn’t run unless you have some employee data sitting in a file. Listing 8-2 says that this file is EmployeeInfo.txt. So before running the code of Listing 8-2, I created a small EmployeeInfo.txt file. The file is shown in Figure 8-3; refer to Figure 8-2 for the resulting output.

![EmployeeInfo.txt file](image)

When you install JCreator from this book’s CD-ROM, the computer copies my EmployeeInfo.txt file exactly where you need it — in the project directory for Listings 8-1 and 8-2. So you can run this section’s code without worrying about the EmployeeInfo.txt file.

Even though you’re not worried about it, you may want to see the EmployeeInfo.txt file in JCreator’s editor. Who knows? You may want to change some of the data in the file. Here’s how you can bring the file into the Editor pane:

1. **With JCreator open, choose File ‹ Open Workspace.**
   An Open dialog box appears.

2. **In the Open dialog box, select Chapter08.jcw, and click Open.**
   The Chapter08 workspace fills JCreator’s File View pane.

3. **In the File View pane, right-click the Listings0801-02 project.**
   A context menu appears.
4. In the context menu, select Show All Files.

Some additional filenames appear under the Listings0801-02 branch of the File View’s tree. One of these other filenames is EmployeeInfo.txt.

5. In the File View’s tree, double-click EmployeeInfo.txt.

When you write your own code, you may need to create files like my EmployeeInfo.txt file. Here’s how you do it:

1. In the File View pane, right-click the name of a project. Then choose Add ➪ New File from the context menu that appears.

JCreator’s File Wizard opens to the File Path tab.

2. In the Name field, type the name of your new data file.

You can type any name that your computer considers to be a valid file name. For this section’s example, I used EmployeeInfo.txt, but other names, such as EmployeeInfo.dat, EmployeeInfo, or Employees123.01.dataFile, are fine. I try to avoid troublesome names (including short, uninformative names and names containing blank spaces), but the name you choose is entirely up to you (and your computer's operating system, and your boss’s whims, and your customer’s specifications).

Always include a dot in File Path tab’s Name field. If the filename has no extension, add a dot at the end of the name. For instance, to create a file named EmployeeInfo (not EmployeeInfo.txt or EmployeeInfo.dat), type EmployeeInfo, exactly as you see it here. If you don’t type your own dot anywhere in the Name field, JCreator adds a default extension to the filename (turning EmployeeInfo into EmployeeInfo.java).

3. Click Finish.

The filename appears in JCreator’s File View pane. A tab with the new filename appears in JCreator’s Editor pane.

4. Type text in the Editor pane.

To create this section’s example, I typed the text shown in Figure 8-3. To create your own example, type whatever text your program needs during its run.

This book’s Web site has tips for readers who need to create data files without using JCreator. This includes instructions for Linux, Unix, and Macintosh environments.
Copying and pasting code

In almost any computer programming language, reading data from a file can be tricky. You add extra lines of code to tell the computer what to do. Sometimes you can copy and paste these lines from other peoples' code. For example, you can follow the pattern in Listing 8-2:

```java
/*
 * The pattern in Listing 8-2
 */
import java.util.Scanner;
import java.io.File;
import java.io.IOException;

class SomeClassName {
    public static void main(String args[]) throws IOException {
        Scanner scannerName =
            new Scanner(new File("SomeFileName"));
        //Some code goes here
        scannerName.nextInt();
        scannerName.nextDouble();
        scannerName.next();
        scannerName.nextLine();
        //Some code goes here
    }
}
```

You want to read data from a file. You start by imagining that you’re reading from the keyboard. Put the usual `Scanner` and `next` codes into your program. Then add some extra items from the Listing 8-2 pattern:

- Add two new import declarations — one for `java.io.File` and another for `java.io.IOException`.
- Type `throws IOException` in your method's header.
- Type `new File("")` in your call to `new Scanner`.
- Take a file that’s already on your hard drive. Type that filename inside the quotation marks.
- Take the word that you use for the name of your scanner. Reuse that word in calls to `next`, `nextInt`, `nextDouble`, and so on.
Occasionally, copying and pasting code can get you into trouble. Maybe you’re writing a program that doesn’t fit the simple Listing 8-2 pattern. You need to tweak the pattern a bit. But in order to tweak the pattern, you need to understand some of the ideas behind the pattern.

That’s how the next section comes to your rescue. The following section covers some of these ideas behind the pattern.

**Reading from a file**

In previous chapters, programs read characters from the computer’s keyboard. These programs use things like `Scanner`, `System.in`, and `nextDouble` — things defined in Java’s API. The `DoPayroll` program in Listing 8-2 puts a new spin on this story. Instead of reading characters from the keyboard, the program reads characters from the `EmployeeInfo.txt` file. The file lives on your computer’s hard drive.

To read characters from a file, you use some of the same things that help you read characters from the keyboard. You use `Scanner`, `nextDouble`, and other goodies. But in addition to these goodies, you have a few extra hurdles to jump. Here’s a list:

- **You need a new File object.** To be more precise, you need a new instance of the API’s `File` class. You get this new instance with code like

  ```java
  new File("EmployeeInfo.txt")
  ```

  The stuff in quotation marks is the name of a file — a file on your computer’s hard drive. The file contains characters like those shown previously in Figure 8-3.

  At this point, the terminology makes mountains out of molehills. Sure, I use the phrases “new File object” and “new File instance,” but all you’re doing is making `new File("EmployeeInfo.txt")` stand for a file on your hard drive. After you shove `new File("EmployeeInfo.txt")` into `new Scanner`,

  ```java
  Scanner diskScanner = 
      new Scanner(new File("EmployeeInfo.txt"));
  ```

  you can forget all about the new File business. From that point on in the code, `diskScanner` stands for the `EmployeeInfo.txt` filename on your computer’s hard drive. (The name `diskScanner` stands for a file on your hard drive just as, in previous examples, the name `myScanner` stands for the computer’s keyboard.)
Creating a new `File` object in Listing 8-2 is like creating a new `Employee` object later in the same listing. It’s also like creating a new `Account` object in the examples of Chapter 7. The only difference is that the `Employee` and `Account` classes are defined in this book’s examples. The `File` class is defined in Java’s API.

When you connect to a disk file with `new Scanner`, don’t forget the `new File` part. If you write `new Scanner("EmployeeInfo.txt")` without `new File`, the compiler won’t mind. (Choosing `Build ‹› Compile Project` will give you a friendly looking `Process completed` message.) But when you run the code, you won’t get anything like the results that you expect to get.

✔ You must refer to the `File` class by its full name — `java.io.File`. You can do this with an import declaration as in Listing 8-2. Alternatively, you can clutter up your code with a statement like:

```java
Scanner diskScanner =
    new Scanner(new java.io.File("EmployeeInfo.txt"));
```

✔ You need a `throws IOException` clause. Lots of things can go wrong when your program connects to `EmployeeInfo.txt`. For one thing, your hard drive may not have a file named `EmployeeInfo.txt`. For another, the file `EmployeeInfo.txt` may be in the wrong directory. To brace for this kind of calamity, the Java programming language takes certain precautions. The language insists that when a disk file is involved, you acknowledge the possible dangers of calling `new Scanner`.

You can acknowledge the hazards in several possible ways, but the simplest way is to use a `throws` clause. In Listing 8-2, the `main` method’s header ends with the words `throws IOException`. By adding these two words, you appease the Java compiler. It’s as if you’re saying “I know that calling `new Scanner` can lead to problems. You don’t have to remind me.” And, sure enough, adding `throws IOException` to your `main` method keeps the compiler from complaining. (Without this `throws` clause, you get an unreported exception error message.)

For the full story on Java exceptions, read Chapter 12. In the meantime, add `throws IOException` to the header of any method that calls `new Scanner(new File(....

✔ You must refer to the `IOException` class by its full name — `java.io.IOException`. You can do this with an import declaration as in Listing 8-2. Alternatively, you can enlarge the `main` method’s `throws` clause:

```java
public static void main(String args[])
    throws java.io.IOException {
```
You must pass the file scanner’s name to the `payOneEmployee` method.

In Listing 7-5 in Chapter 7, the `getInterest` method has a parameter named `percentageRate`. Whenever you call the `getInterest` method, you hand an extra, up-to-date piece of information to the method. (You hand a number — an interest rate — to the method. Figure 7-7 illustrates the idea.)

The same thing happens in Listing 8-2. The `payOneEmployee` method has a parameter named `aScanner`. Whenever you call the `payOneEmployee` method, you hand an extra, up-to-date piece of information to the method. (You hand a scanner — a reference to a disk file — to the method.)

You may wonder why the `payOneEmployee` method needs a parameter. After all, in Listing 8-2, the `payOneEmployee` method always reads data from the same file. Why bother informing this method, each time you call it, that the disk file is still the `EmployeeInfo.txt` file?

Well, there are plenty of ways to shuffle the code in Listing 8-2. Some ways don’t involve a parameter. But the way that this example has arranged things, you have two separate methods — a `main` method and a `payOneEmployee` method. You create a scanner once inside the `main` method and then use the scanner three times — once inside each call to the `payOneEmployee` method.

Anything that you define inside a method is like a private joke that’s known only to the code inside that method. So, the `diskScanner` that you define inside the `main` method isn’t automatically known inside the `payOneEmployee` method. To make the `payOneEmployee` method aware of the disk file, you pass `diskScanner` from the `main` method to the `payOneEmployee` method.

To read more about variables that you declare inside (and outside) of methods, see Chapter 10.

Who moved my file?

If you installed JCreator from this book’s CD-ROM, your MyProjects directory has a subdirectory named Listings0801-02. That Listings0801-02 directory comes with files named `Employee.java` and `DoPayroll.java` — the code in Listings 8-1 and 8-2. The Listings0801-02 directory also contains the `EmployeeInfo.txt` file. That’s good, because if the `EmployeeInfo.txt` file isn’t where it belongs, the whole project doesn’t run properly. Instead, you get a `FileNotFoundException`.
In general, when you get a `FileNotFoundException`, some file that your program needs isn’t available to your program. This is an easy mistake to make. It can be frustrating because to you, a file such as `EmployeeInfo.txt` may look like it’s available to your program. But remember — computers are stupid. If you make a tiny mistake, the computer can’t read between the lines for you. So if your `EmployeeInfo.txt` file isn’t in the right directory on your hard drive or the filename is spelled incorrectly, the computer chokes when it tries to run your code.

Sometimes you know darn well that an `EmployeeInfo.txt` (or `whatever.xyz`) file exists on your hard drive. But when you run your program, you still get a mean-looking `FileNotFoundException`. When this happens, the file is usually in the wrong directory on your hard drive. (Of course, it depends on your point of view. Maybe the file is in the right directory, but you’ve told your Java program to look for the file in the wrong directory.) When this happens, try copying the file to some other directories on your hard drive and rerunning your code. (Subdirectories of JCreator’s `MyProjects` directory are always good places to put files.) Stare carefully at the names and locations of files on your hard drive until you figure out what’s wrong.

**Adding directory names to your filenames**

You can specify a file’s exact location in your Java code. Code like

```java
new File("C:\Program Files\Xinox Software\JCreatorV3 LE\MyProjects\Listings0801-02\EmployeeInfo.txt")
```

looks really ugly, but it works.

In the previous paragraph, notice the double backslashes in "C:\Program Files\Xinox Software ..." If you’re a Windows MS-DOS user, you’d be tempted to write `C:\Program Files\Xinox Software` with single backslashes. But in Java, the single backslash has its own special meaning. (For example, in Listing 7-7, \n means to go to the next line.) So in Java, to indicate a backslash inside a quoted string, you use a double backslash instead.

If you know where your Java program looks for files, you can worm your way from that place to the directory of your choice. For example, the code in Listing 8-2 normally looks for the `EmployeeInfo.txt` file in a directory named `Listings0801-02`. So as an experiment, go to the `Listings0801-02` directory and create a new subdirectory named `dataFiles`. Then move my `EmployeeInfo.txt` file to the new `dataFiles` directory. To read numbers and words from the file that you moved, modify Listing 8-2 with the code

```java
new File("dataFiles\EmployeeInfo.txt")
```
Reading a line at a time

In Listing 8-2, the `payOneEmployee` method illustrates some useful tricks for reading data. In particular, every scanner that you create has a `nextLine` method. (You might not use this `nextLine` method, but the method is available nonetheless.) When you call a scanner’s `nextLine` method, the method grabs everything up to the end of the current line of text. In Listing 8-2, a call to `nextLine` can read a whole line from the `EmployeeInfo.txt` file. (In another program, a scanner’s `nextLine` call may read everything the user types on the keyboard, up to the pressing of the Enter key.)

Notice my careful choice of words — `nextLine` reads everything up to the end of the current line. Unfortunately, what it means to read up to the end of the current line isn’t always what you think it means. Intermingling `nextInt`, `nextDouble`, and `nextLine` calls can be messy. You have to watch what you’re doing and check your program’s output carefully.

To understand all this, you need to be painfully aware of a data file’s line breaks. Think of a line break as an extra character, stuck between one line of text and the next. Then imagine that calling `nextLine` means to read everything up to and including the next line break.

Now take a look at Figure 8-4.

- If one call to `nextLine` reads `Barry Burd[LineBreak]`, the subsequent call to `nextLine` reads `CEO[LineBreak].`  
- If one call to `nextDouble` reads the number 5000.00, the subsequent call to `nextLine` reads the `[LineBreak]` that comes immediately after the number 5000.00. (That’s all the `nextLine` reads — a `[LineBreak]` and nothing more.)  
- If a call to `nextLine` reads the `[LineBreak]` after the number 5000.00, the subsequent call to `nextLine` reads `Harriet Ritter[LineBreak].`

So after reading the number 5000.00, you need two calls to `nextLine` in order to scoop up the name `Harriet Ritter`. The mistake that I usually make is to forget the first of those two calls.

Look again at the file in Figure 8-3. For this section’s code to work correctly, you must have a line break after the last 10000.00. If you don’t, a final call to `nextLine` makes your program crash and burn. The error message reads `NoSuchElementException: No line found.`
I’m always surprised by the number of quirks that I find in each programming language’s scanning methods. For example, the first `nextLine` that reads from the file in Figure 8-3 devours Barry Burd from the file. But that `nextLine` call delivers Barry Burd (without any line break) to the running code. So `nextLine` looks for a line break, and then `nextLine` loses the line break. Yes, this is a subtle point. And no, this subtle point hardly ever causes problems for anyone.

If this business about `nextDouble` and `nextLine` confuses you, please don’t put the blame on Java. Mixing input calls is delicate work in any computer programming language. And the really nasty thing is that each programming language approaches the problem a little differently. What you find out about `nextLine` in Java helps you understand the issues when you get to know C++ or Visual Basic, but it doesn’t tell you all the details. Each language’s details are unique to that language. (Yes, it’s a big pain. But because all computer programmers become rich and famous, the pain eventually pays off.)

**Defining Subclasses (What It Means to Be a Full-Time Employee or a Part-Time Employee)**

This time last year, your company paid $10 million for a piece of software. That software came in the `Employee.class` file. People at Burd Brain Consulting (the company that created the software) don’t want you to know
about the innards of the software (otherwise, you may steal their ideas). So you don’t have the Java program file that the software came from. (In other words, you don’t have Employee.java.) You can run the bytecode in the Employee.class file. You can also read the documentation in a Web page named Employee.html. But you can’t see the statements inside the Employee.java program, and you can’t change any of the program’s code.

Since this time last year, your company has grown. Unlike the old days, your company now has two kinds of employees: full-time and part-time. Each full-time employee is on a fixed, weekly salary. (If the employee works nights and weekends, then in return for this monumental effort, the employee receives a hearty handshake.) In contrast, each part-time employee works for an hourly wage. Your company deducts an amount from each full-time employee’s paycheck to pay for the company’s benefits package. Part-time employees, however, don’t get benefits.

The question is, how can the software that your company bought last year keep up with the company’s growth? You invested in a great program to handle employees and their payroll, but the program doesn’t differentiate between your full-time and part-time employees. You have several options:

✔ Call your next-door neighbor, whose 12-year-old child knows more about computer programming than anyone in your company. Get this uppity little brat to take the employee software apart, rewrite it, and hand it back to you with all the changes and additions your company requires.

On second thought, you can’t do that. No matter how smart that kid is, the complexities of the employee software will probably confuse the kid. By the time you get the software back, it’ll be filled with bugs and inconsistencies. Besides, you don’t even have the Employee.java file to hand to the kid. All you have is the Employee.class file, which can’t be read or modified with a text editor. (See Chapter 2.) Besides, your kid just beat up the neighbor’s kid. You don’t want to give your neighbor the satisfaction of seeing you beg for the whiz kid’s help.

✔ Scrap the $10 million employee software. Get someone in your company to rewrite the software from scratch.

In other words, say goodbye to your time and money.

✔ Write a new front end for the employee software. That is, build a piece of code that does some preliminary processing on full-time employees and then hands the preliminary results to your $10 million software. Do the same for part-time employees.

This idea could be decent or spell disaster. Are you sure that the existing employee software has convenient hooks in it? (That is, does the employee software contain entry points that allow your front-end
software to easily send preliminary data to the expensive employee software?) Remember, this plan treats the existing software as one big, monolithic lump, which can become cumbersome. Dividing the labor between your front-end code and the existing employee program is difficult. And if you add layer upon layer to existing black box code, you’ll probably end up with a fairly inefficient system.

✔ Call Burd Brain Consulting, the company that sold you the employee software. Tell Dr. Burd that you want the next version of his software to differentiate between full-time and part-time employees.

“No problem,” says Dr. Burd. “It’ll be ready by the start of the next fiscal quarter.” That evening, Dr. Burd makes a discrete phone call to his next-door neighbor. . . .

✔ Create two new Java classes named *FullTimeEmployee* and *PartTimeEmployee*. Have each new class extend the existing functionality of the expensive *Employee* class. But have each new class define its own specialized functionality for certain kinds of employees.

Way to go! Figure 8-5 shows the structure that you want to create.

![Figure 8-5: The Employee class family tree.](image)

Creating a subclass

In Listing 8-1, I define an *Employee* class. I can use what I define in Listing 8-1 and extend the definition to create new, more specialized classes. So in Listing 8-3, I define a new class — a *FullTimeEmployee* class.
Listing 8-3: What Is a FullTimeEmployee?

class FullTimeEmployee extends Employee {
    private double weeklySalary;
    private double benefitDeduction;

    public void setWeeklySalary(double weeklySalaryIn) {
        weeklySalary = weeklySalaryIn;
    }

    public double getWeeklySalary() {
        return weeklySalary;
    }

    public void setBenefitDeduction(double benefitDedIn) {
        benefitDeduction = benefitDedIn;
    }

    public double getBenefitDeduction() {
        return benefitDeduction;
    }

    public double findPaymentAmount() {
        return weeklySalary - benefitDeduction;
    }
}

Looking at Listing 8-3, you can see that each instance of the FullTimeEmployee class has two variables: weeklySalary and benefitDeduction. But are those the only variables that each FullTimeEmployee instance has? No, they’re not. The first line of Listing 8-3 says that the FullTimeEmployee class extends the existing Employee class. This means that in addition to having a weeklySalary and a benefitDeduction, each FullTimeEmployee instance also has two other variables: name and jobTitle. These two variables come from the definition of the Employee class, which you can find in Listing 8-1.

In Listing 8-3, the magic word is the word extends. When one class extends an existing class, the extending class automatically inherits functionality that’s defined in the existing class. So, the FullTimeEmployee class inherits the name and jobTitle variables. The FullTimeEmployee class also inherits all the methods that are declared in the Employee class — setName, getName, setJobTitle, getJobTitle, and cutCheck. The FullTimeEmployee class is a subclass of the Employee class. That means the Employee class is the superclass of the FullTimeEmployee class. You can also talk in terms of blood relatives. The FullTimeEmployee class is the child of the Employee class, and the Employee class is the parent of the FullTimeEmployee class.

It’s almost (but not quite) as if the FullTimeEmployee class were defined by the code in Listing 8-4.
import static java.lang.System.out;

class FullTimeEmployee {
    private String name;
    private String jobTitle;
    private double weeklySalary;
    private double benefitDeduction;

    public void setName(String nameIn) {
        name = nameIn;
    }

    public String getName() {
        return name;
    }

    public void setJobTitle(String jobTitleIn) {
        jobTitle = jobTitleIn;
    }

    public String getJobTitle() {
        return jobTitle;
    }

    public void setWeeklySalary(double weeklySalaryIn) {
        weeklySalary = weeklySalaryIn;
    }

    public double getWeeklySalary() {
        return weeklySalary;
    }

    public void setBenefitDeduction(double benefitDedIn) {
        benefitDeduction = benefitDedIn;
    }

    public double getBenefitDeduction() {
        return benefitDeduction;
    }

    public double findPaymentAmount() {
        return weeklySalary - benefitDeduction;
    }

    public void cutCheck(double amountPaid) {
        out.printf("Pay to the order of %s ", name);
        out.printf("(%s) ***$", jobTitle);
        out.printf("%,.2f\n", amountPaid);
    }
}
Why does the title for Listing 8-4 call that code fake? (Should the code feel insulted?) Well, the main difference between Listing 8-4 and the inheritance situation in Listings 8-1 and 8-3 is this: A child class can’t directly reference the private variables of its parent class. To do anything with the parent class’s private variables, the child class has to call the parent class’s accessor methods. Back in Listing 8-3, calling setName("Rufus") would be legal, but the code name="Rufus" wouldn’t be. If you believe everything you read in Listing 8-4, you think that code in the FullTimeEmployee class can do name="Rufus". Well, it can’t. (My, what a subtle point this is!)

You don’t need the Employee.java file on your hard drive to write code that extends the Employee class. All you need is the file Employee.class.

Creating subclasses is habit-forming

After you’re accustomed to extending classes, you can get extend-happy. If you created a FullTimeEmployee class, you might as well create a PartTimeEmployee class, as shown in Listing 8-5.

Listing 8-5: What Is a PartTimeEmployee?

class PartTimeEmployee extends Employee {
    private double hourlyRate;

    public void setHourlyRate(double rateIn) {
        hourlyRate = rateIn;
    }

    public double getHourlyRate() {
        return hourlyRate;
    }

    public double findPaymentAmount(int hours) {
        return hourlyRate * hours;
    }
}

Unlike the FullTimeEmployee class, PartTimeEmployee has no salary or deduction. Instead PartTimeEmployee has a hourlyRate variable. (Adding a numberOfHoursWorked variable would also be a possibility. I chose not to do this, figuring that the number of hours a part-time employee works will change drastically from week to week.)
Using Subclasses

The previous section tells a story about creating subclasses. It’s a good story, but it’s incomplete. Creating subclasses is fine, but you gain nothing from these subclasses unless you write code to use them. So in this section, you explore code that uses subclasses.

Now the time has come for you to classify yourself as either a type-F person or a type-P person. A type-F person wants to see the fundamentals. (The letter F stands for fundamentals.) “Show me a program that lays the principles out in their barest, most basic form,” says the type-F person. A type-F person isn’t worried about bells and whistles. The bells come later, and the whistles may never come at all. If you’re a type-F person, you want to see a program that uses subclasses, and then moves out of your way so you can get some work done.

On the other hand, a type-P person wants practical applications. (The letter P stands for practical.) Type-P people need to see ideas in context; otherwise the ideas float away too quickly. “Show me a program that demonstrates the usefulness of subclasses,” says the type-P person. “I have no use for your stinking abstractions. I want real-life examples, and I want them now!”

Because I’m always aiming to please my reader, this section has two (count ’em — two) examples that make use of the previous section’s subclasses. Listing 8-6, which is for the type-F crowd, is lean and simple and makes good bedtime reading. On the other hand, Listing 8-7, which is for type-P fanatics, shows how subclasses fit into a useful context.

So that’s it. Choose your poison and read on.

A program for the minimalist

Listing 8-6 shows you a bare-bones program that uses the subclasses FullTimeEmployee and PartTimeEmployee. Figure 8-6 shows the program’s output.

Listing 8-6: Use Subclasses and Then Leave Me Alone

class DoPayrollTypeF {
    public static void main(String args[]) {
        FullTimeEmployee ftEmployee = new FullTimeEmployee();
    }
}
To understand Listing 8-6, you need to keep an eye on three classes: Employee, FullTimeEmployee, and PartTimeEmployee. (For a look at the code that defines these classes, see Listings 8-1, 8-3, and 8-5.)

The first half of Listing 8-6 deals with a full-time employee. Notice how so many methods are available for use with the ftEmployee variable. For instance, you can call ftEmployee.setWeeklySalary because ftEmployee has type FullTimeEmployee. You can also call ftEmployee.setName because the FullTimeEmployee class extends the Employee class.

Because cutCheck is declared in the Employee class, you can call ftEmployee.cutCheck. But you can also call ftEmployee.findPaymentAmount because a findPaymentAmount method is in the FullTimeEmployee class.

**Making types match**

Look again at the first half of Listing 8-6. Take special notice of that last statement — the one in which the full-time employee is actually cut a check. The statement forms a nice, long chain of values and their types. You can see this by reading the statement from the inside out.
Method `ftEmployee.findPaymentAmount` is called with an empty parameter list (Listing 8-6). That's good, because the `findPaymentAmount` method takes no parameters (Listing 8-3).

The `findPaymentAmount` method returns a value of type `double` (again, Listing 8-3).

The `double` value that `ftEmployee.findPaymentAmount` returns is passed to method `ftEmployee.cutCheck` (Listing 8-6). That's good, because the `cutCheck` method takes one parameter of type `double` (Listing 8-1).

For a fanciful graphic illustration, see Figure 8-7.

Always feed a method the value types that it wants in its parameter list.

**The second half of the story**

In the second half of Listing 8-6, the code creates an object of type `PartTimeEmployee`. A variable of type `PartTimeEmployee` can do some of the same things a `FullTimeEmployee` variable can do. But the `PartTimeEmployee` class doesn’t have the `setWeeklySalary` and `setBenefitDeduction` methods. Instead, the `PartTimeEmployee` class has the `setHourlyRate` method. (See Listing 8-5.) So, in Listing 8-6, the next-to-last line is a call to the `setHourlyRate` method.

The last line of Listing 8-6 is by far the most interesting. On that line, the code hands the number 10 (the number of hours worked) to the `findPaymentAmount` method. Compare this with the earlier call to `findPaymentAmount` — the call for the full-time employee in the first half of Listing 8-6. Between the two subclasses, `FullTimeEmployee` and `PartTimeEmployee`, are two different `findPaymentAmount` methods. The two methods have two different kinds of parameter lists:
The FullTimeEmployee class's findPaymentAmount method takes no parameters (Listing 8-3).

The PartTimeEmployee class's findPaymentAmount method takes one int parameter (Listing 8-5).

This is par for the course. Finding the payment amount for a part-time employee isn’t the same as finding the payment amount for a full-time employee. A part-time employee’s pay changes each week, depending on the number of hours the employee works in a week. The full-time employee’s pay stays the same each week. So the FullTimeEmployee and PartTimeEmployee classes both have findPaymentAmount methods, but each class’s method works quite differently.

A program for the maximalist

If you crave useful results and practical applications, you either skipped over the last listing or gritted your teeth while you read through it. Listing 8-7 gives you the same information with a more practical point of view. Of course, there’s a price. Listing 8-7 is longer and more complicated than the listing in the previous section. Oh, well!

Listing 8-7: Big-Time Payroll Program

```java
import static java.lang.System.out;
import java.util.Scanner;
import java.io.File;
import java.io.IOException;
class DoPayrollTypeP {
    public static void main(String args[]) throws IOException {
        Scanner diskScanner = new Scanner(new File("EmpInfoNew.txt"));
        Scanner kbdScanner = new Scanner(System.in);
        for (int empNum = 1; empNum <= 3; empNum++) {
            payOneFTEmployee(diskScanner);
        }
        for (int empNum = 4; empNum <= 6; empNum++) {
            payOnePTEmployee(diskScanner, kbdScanner);
        }
    }
}
```
public static void payOneFTEmployee(Scanner diskScanner) {
    FullTimeEmployee employee = new FullTimeEmployee();

    employee.setName(diskScanner.nextLine());
    employee.setJobTitle(diskScanner.nextLine());
    employee.setWeeklySalary(diskScanner.nextDouble());
    employee.setBenefitDeduction(diskScanner.nextDouble());
    diskScanner.nextLine();
    diskScanner.nextLine(); // Reads the dashed line that
    // separates two employees

    employee.cutCheck(employee.findPaymentAmount());
    out.println();
}

public static void payOnePTEmployee(Scanner diskScanner, Scanner kbdScanner) {
    PartTimeEmployee employee = new PartTimeEmployee();

    employee.setName(diskScanner.nextLine());
    employee.setJobTitle(diskScanner.nextLine());
    employee.setHourlyRate(diskScanner.nextDouble());
    diskScanner.nextLine();
    diskScanner.nextLine(); // Reads the dashed line that
    // separates two employees

    out.print("Enter ");
    out.print(employee.getName());
    out.print("'s hours worked this week: ");
    int hours = kbdScanner.nextInt();

    employee.cutCheck(employee.findPaymentAmount(hours));
    out.println();
}

For all its complexity, the code in Listing 8-7 still isn’t a full-blown payroll program. It’s a toy program, but it’s a bit more realistic than the program in Listing 8-6. The code in Listing 8-7 writes checks for six employees — three full-time employees and three part-time employees. Calls to payOneFTEmployee and payOnePTEmployee make sure that each employee receives a check. Each of these payOneEmployee methods reads data from a file and uses the data to fill the employee object’s variables with values. Figure 8-8 shows the file that I used to test Listing 8-7, and the resulting run is shown in Figure 8-9.
Compared with its full-time cousin, the `payOnePTEmployee` method pulls one extra idea out of its bag of tricks. When the time comes to get the number of hours the employee worked, the `payOnePTEmployee` method doesn't consult a disk file. Instead, the method asks the user for live keyboard input. The thought here is that the disk file is where all the long-term information about employees lives. Because the number of hours an employee worked this week isn't long-term information, the `payOnePTEmployee` method gets the user to enter this information on the fly.

The `payOnePTEmployee` method reads a name, a job title, and an hourly rate from the disk file. Then the method reads a number of hours from the keyboard. Because the `payOnePTEmployee` method reads data from two different sources, you pass two different scanners to the method. In the method's parameter list, you separate the two items with a comma.
Overriding Existing Methods
(Changing the Payments for Some of Your Employees)

Wouldn’t you know it! Some knucklehead in the human resources department offered double pay for overtime to one of your part-time employees. Now word is getting around, and some of the other part-timers want double pay for their overtime work. If this keeps up, you’ll end up in the poorhouse, so you need to send out a memo to all the part-time employees, explaining why earning more money is not to their benefit.

In the meantime, you have two kinds of part-time employees — the ones who receive double pay for overtime hours and the ones who don’t — so you need to modify your payroll software. What are your options?

✓ Well, you can dig right into the PartTimeEmployee class code, make a few changes, and hope for the best. (Not a good idea!)

✓ You can follow the previous section’s advice and create a subclass of the existing PartTimeEmployee class. “But wait,” you say. “The existing PartTimeEmployee class already has a findPaymentAmount method. Do I need some tricky way of bypassing this existing findPaymentAmount method for each double-pay-for-overtime employee?”

At this point, you can thank your lucky stars that you’re doing object-oriented programming in Java. With object-oriented programming, you can create a subclass that overrides the functionality of its parent class. Listing 8-8 has just such a subclass.

Listing 8-8: Yet Another Subclass

class PartTimeWithOver extends PartTimeEmployee {
    public double findPaymentAmount(int hours) {
        if(hours <= 40) {
            return getHourlyRate() * hours;
        } else {
            return getHourlyRate() * 40 +
                    getHourlyRate() * 2 * (hours - 40);
        }
    }
}
Figure 8-10 shows the relationship between the code in Listing 8-8 and other pieces of code in this chapter. In particular, PartTimeWithOver is a subclass of a subclass. In object-oriented programming, a chain of this kind is not the least bit unusual. In fact, as subclasses go, this chain is rather short.

The PartTimeWithOver class extends the PartTimeEmployee class, but PartTimeWithOver picks and chooses what it wants to inherit from the PartTimeEmployee class. Because PartTimeWithOver has its own declaration for the findPaymentAmount method, the PartTimeWithOver class doesn't inherit a findPaymentAmount method from its parent. (See Figure 8-11.)

According to the official terminology, the PartTimeWithOver class overrides its parent class's findPaymentAmount method. If you create an object from the PartTimeWithOver class, that object has the name, jobTitle, hourlyRate, and cutCheck of the PartTimeEmployee class, but the object has the findPaymentAmount method that's defined in Listing 8-8.

If you need clarification on the stuff that you just read, look at the code in Listing 8-9. A run of that code is shown in Figure 8-12.
Listing 8-9: Testing the Code from Listing 8-8

class DoPayrollTypeF {
    public static void main(String args[]) {
        FullTimeEmployee ftEmployee = new FullTimeEmployee();
        ftEmployee.setName("Barry Burd");
        ftEmployee.setJobTitle("CEO");
        ftEmployee.setWeeklySalary(5000.00);
        ftEmployee.setBenefitDeduction(500.00);
        ftEmployee.cutCheck(ftEmployee.findPaymentAmount());

        PartTimeEmployee ptEmployee = new PartTimeEmployee();
        ptEmployee.setName("Chris Apelian");
        ptEmployee.setJobTitle("Computer Book Author");
        ptEmployee.setHourlyRate(7.53);
        ptEmployee.cutCheck(ptEmployee.findPaymentAmount(50));

        PartTimeWithOver ptoEmployee = new PartTimeWithOver();
        ptoEmployee.setName("Steve Surace");
        ptoEmployee.setJobTitle("Driver");
        ptoEmployee.setHourlyRate(7.53);
        ptoEmployee.cutCheck(ptoEmployee.findPaymentAmount(50));
    }
}
The code in Listing 8-9 writes checks to three employees. The first employee is a full-timer. The second is one of those part-time employees who hasn’t yet gotten wind of the overtime payment scheme. The third employee knows about the overtime payment scheme and demands a fair wage.

With the subclasses, all three of these employees coexist in Listing 8-9. Sure, one subclass comes from the old PartTimeEmployee class, but that doesn’t mean you can’t create an object from the PartTimeEmployee class. In fact, Java is very smart about this. Listing 8-9 has three calls to the findPaymentAmount method, and each call reaches out to a different version of the method.

✔ In the first call, ftEmployee.findPaymentAmount, the ftEmployee variable is an instance of the FullTimeEmployee class. So the method that’s called is the one in Listing 8-3.

✔ In the second call, ptEmployee.findPaymentAmount, the ptEmployee variable is an instance of the PartTimeEmployee class. So the method that’s called is the one in Listing 8-5.

✔ In the third call, ptoEmployee.findPaymentAmount, the ptoEmployee variable is an instance of the PartTimeWithOver class. So the method that’s called is the one in Listing 8-8.

This code is fantastic. It’s clean, elegant, and efficient. With all the money that you save on software, you can afford to pay everyone double for overtime hours. (Whether you do that or keep the money for yourself is another story.)
Ms. Jennie Rebekah Burd  
121 Schoolhouse Lane  
Anywhere, Kansas  

Dear Ms. Burd,

In response to your letter of June 21, I believe I can say with complete assurance that objects are not created spontaneously from nothing. Although I have never actually seen an object being created (and no one else in this office can claim to have seen an object in its moment of creation), I have every confidence that some process or other is responsible for the building of these interesting and useful thingamajigs. We here at ClassesAndObjects.com support the unanimous opinions of both the scientific community and the private sector on matters of this nature. Furthermore, we agree with the recent finding of a Blue Ribbon Presidential Panel, which concludes beyond any doubt that spontaneous object creation would impede the present economic outlook.

Please be assured that I have taken all steps necessary to ensure the safety and well being of you, our loyal customer. If you have any further questions, please do not hesitate to contact our complaint department. The department’s manager is Mr. Blake Wholl. You can contact him by visiting our company’s Web site.

Once again, let me thank you for your concern, and I hope you continue to patronize ClassesAndObjects.com.

Yours truly,

Mr. Scott Brickenchicker  
The one who couldn’t get on the elevator in Chapter 4
Defining Constructors (What It Means to Be a Temperature)

Here’s a statement that creates an object:

```java
Account myAccount = new Account();
```

I know this works — I got it from one of my own examples in Chapter 7. Anyway, in Chapter 7, I say, “when the computer executes `new Account()`, you’re creating an object by calling the `Account` class’s constructor.” What does this mean?

Well, when you ask the computer to create a new object, the computer responds by performing certain actions. For starters, the computer finds a place in its memory to store information about the new object. If the object has variables, the variables should eventually have meaningful values.

So one question is, when you ask the computer to create a new object, can you control what’s placed in the object’s variables? And what if you’re interested in doing more than filling variables? Perhaps, when the computer creates a new object, you have a whole list of jobs for the computer to carry out. For instance, when the computer creates a new window object, you want the computer to realign the sizes of all the buttons in that window.

Creating a new object can involve all kinds of tasks, so in this chapter, you create constructors. A constructor tells the computer to perform a new object’s startup tasks.

What is a temperature?

“Good morning, and welcome to Object News. The local temperature in your area is a pleasant 73 degrees Fahrenheit.”

Each temperature consists of two things — a number and a temperature scale. The code in Listing 9-1 makes this fact abundantly clear.

Listing 9-1: The Temperature Class

```java
class Temperature {
    private double number;
    private ScaleName scale;
}
```
public Temperature() {
    number = 0.0;
    scale = ScaleName.fahrenheit;
}

public Temperature(double number) {
    this.number = number;
    scale = ScaleName.fahrenheit;
}

public Temperature(ScaleName scale) {
    number = 0.0;
    this.scale = scale;
}

public Temperature(double number, ScaleName scale) {
    this.number = number;
    this.scale = scale;
}

public void setNumber(double number) {
    this.number = number;
}

public double getNumber() {
    return number;
}

public void setScale(ScaleName scale) {
    this.scale = scale;
}

public ScaleName getScale() {
    return scale;
}
}

At the top of the code in Listing 9-1 are two variables: `number` and `scale`. A number is just a double value, such as 32.0 or 70.52. A scale is an enum value. I define the enum type `ScaleName` in Listing 9-2.

For an introduction to enum types, see Chapter 6.

**Listing 9-2: The ScaleName enum Type**

```java
enum ScaleName {celsius, fahrenheit, kelvin, rankine};
```
The code in Listing 9-1 also has the usual setter and getter methods (accessor methods for the number and scale variables).

For some good reading on setter and getter methods (also known as accessor methods) see Chapter 7.

On top of all that, Listing 9-1 has four other method-like looking things. Each of these method-like things has the name Temperature, which happens to be the same as the name of the class. None of these Temperature method-like things has a return type of any kind — not even void, which is the copout return type.

Each of these method-like things is called a constructor. A constructor is like a method, except that a constructor has a very special purpose — creating new objects.

Whenever the computer creates a new object, the computer executes the statements inside a constructor.

**What you can do with a temperature**

Listing 9-3 gives form to some of the ideas that I describe above. In Listing 9-3, you call the constructors that are declared back in Listing 9-1. Figure 9-1 shows what happens when you run all this code.

### Listing 9-3: Using the Temperature Class

```java
import static java.lang.System.out;

class UseTemperature {
    public static void main(String args[]) {
        final String format = "%5.2f degrees %s
";

        Temperature temp = new Temperature();
        temp.setNumber(70.0);
        temp.setScale(ScaleName.fahrenheit);
        out.printf(format, temp.getNumber(), temp.getScale());

        temp = new Temperature(32.0);
        out.printf(format, temp.getNumber(), temp.getScale());

        temp = new Temperature(ScaleName.celsius);
        out.printf(format, temp.getNumber(), temp.getScale());

        temp = new Temperature(2.73, ScaleName.kelvin);
        out.printf(format, temp.getNumber(), temp.getScale());
    }
}
```
In Listing 9-3, each statement of the kind

```java
temp = new Temperature(blah, blah, blah);
```

calls one of the constructors from Listing 9-1. So, by the time the code in Listing 9-3 is done running, it creates four instances of the `Temperature` class. Each instance is created by calling a different constructor from Listing 9-1.

### Calling new Temperature (32.0):
### A case study

When the computer executes one of the `new Temperature` statements in Listing 9-3, the computer has to decide which of the constructors in Listing 9-1 to use. The computer decides by looking at the `parameter list` (the stuff in parentheses) after the words `new Temperature`. For instance, when the computer executes

```java
temp = new Temperature(32.0);
```

from Listing 9-3, the computer says to itself, “The number 32.0 in parentheses is a double value.” One of the `Temperature` constructors in Listing 9-1 has just one parameter with type `double`. The constructor’s header looks like this.

```java
public Temperature(double number)
```

“So, I guess I’ll execute the statements inside that particular constructor.” The computer goes on to execute the following statements:

```java
this.number = number;
scale = ScaleName.fahrenheit;
```

As a result, you get a brand-new object, whose number variable has the value 32.0, and whose `scale` variable has the value `fahrenheit`. 

<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>70.00 degrees fahrenheit</td>
</tr>
<tr>
<td>32.00 degrees fahrenheit</td>
</tr>
<tr>
<td>0.00 degrees celsius</td>
</tr>
<tr>
<td>273 degrees kelvin</td>
</tr>
</tbody>
</table>
In the two lines of code, you have two statements that set values for the variables number and scale. Take a look at the second of these statements, which is a bit easier to understand. The second statement sets the new object’s scale variable to fahrenheit. You see, the constructor’s parameter list is (double number), and that list doesn’t include a scale value. So whoever programmed this code had to make a decision about what value to use for the scale variable. The programmer could have chosen fahrenheit or celsius, but she could also have chosen kelvin or rankine. (This programmer happens to live in New Jersey, in the United States, where people commonly use the old Fahrenheit temperature scale.)

Marching back to the first of the two statements, this first statement assigns a value to the new object’s number variable. The statement uses a cute trick that you can see in many constructors (and in other methods that assign values to objects’ variables). To understand the trick, take a look at Listing 9-4. The listing shows you two ways that I could have written the same constructor code.

Listing 9-4: Two Ways to Accomplish the Same Thing

```
//Use this constructor ...

public Temperature(double whatever) {
    number = whatever;
    scale = ScaleName.fahrenheit;
}

//... or use this constructor ...

public Temperature(double number) {
    this.number = number;
    scale = ScaleName.fahrenheit;
}

//... but don't put both constructors in your code.
```

Listing 9-4 has two constructors in it. In the first constructor, I use two different names — number and whatever. In the second constructor, I don’t need two names. Instead of making up a new name for the constructor’s parameter, I reuse an existing name by writing this.number.

So here’s what’s going on in Listing 9-1:

- In the statement `this.number = number`, the name `this.number` refers to the new object’s number variable — the variable that’s declared near the very top of Listing 9-1. (See Figure 9-2.)
- In the statement `this.number = number`, the word number (on its own, without this) refers to the constructor’s parameter. (Again, see Figure 9-2.)
What’s this all about?

Suppose your code contains a constructor — the first of the two constructors in Listing 9-4. The `whatever` parameter is passed a number like 32.0 for instance. Then the first statement in the constructor’s body assigns that value, 32.0, to the new object’s `number` variable. The code works. But in writing this code, you had to make up a new name for a parameter — the name `whatever`. And the only purpose for this new name is to hand a value to the object’s `number` variable. What a waste! To distinguish between the parameter and the `number` variable, you gave a name to something that was just momentary storage for the `number` value.

Making up names is an art, not a science. I’ve gone through plenty of naming phases. Years ago, whenever I needed a new name for a parameter, I picked a confusing misspelling of the original variable name. (I’d name the parameter something like `numbr` or `numhber`.) I’ve also tried changing a variable name’s capitalization to come up with a parameter name. (I’d use parameter names like `Number` or `nUMBER`.) In Chapter 8, I name all my parameters by adding the suffix `In` to their corresponding variable names. (The `jobTitle` variable matched up with the `jobTitleIn` parameter.) None of these naming schemes works very well. I can never remember the quirky new names that I’ve created. The good news is that this parameter naming effort isn’t necessary. You can give the parameter the same name as the variable. To distinguish between the two, you use the Java keyword `this`.

```
class Temperature {
    private double number;
    private ScaleName scale;

    public Temperature(double number) {
        this.number = number;
        scale = ScaleName.fahrenheit;
    }
}
```

In general, `this.someName` refers to a variable belonging to the object that contains the code. In contrast, plain old `someName` refers to the closest place where `someName` happens to be declared. In the statement `this.number = number` (Listing 9-1), that closest place happens to be the `Temperature` constructor’s parameter list.
enum types as first-class citizens

A peak at the code from this book's CD-ROM tells an interesting story. The project for this section’s example contains three Java files: Temperature.java (Listing 9-1), ScaleName.java (Listing 9-2), and UseTemperature.java (Listing 9-3). The big news in this trio is ScaleName.java. Why does this wimpy little one-line enum type deserve to be in its own separate Java file?

Well, two issues exist here, and both of them are important:

- An enum type is a class in disguise. When the Java compiler gets hold of your enum declaration, the compiler immediately turns the enum type into a class:

```java
enum ScaleName extends Enum {
    celsius = new ScaleName("celsius", 0);
    fahrenheit = new ScaleName("fahrenheit", 1);
    kelvin = new ScaleName("kelvin", 2);
    rankine = new ScaleName("rankine", 3);
}
```

This normally happens behind the scenes. So in previous examples (Listing 6-5, for instance), you don’t have to think about it. But in most of this book’s examples (and according to standard Java programming practice), each Java class lives in a .java file all its own. Because ScaleName is a class, having a separate ScaleName.java file makes perfect sense.

Back in Listing 6-5, I stuffed three enum type declarations inside another class — a class named Clue. In Chapter 6, this doesn’t seem unusual, but now you may be thinking, “A class can be nested inside another class.” Well, stop thinking that way. It’s true that Java supports a feature called inner classes — classes defined within other classes. It’s also true that this inner class feature allows you to define a Suspect enum type inside a Clue class. What’s not true is that novice Java programmers should use inner classes, except in the narrowly defined context of enum types. So in general, when you’re tempted to put one class inside another, don’t do it.

- The ScaleName enum type must be available to both the Temperature and the UseTemperature classes. In the first draft of this section’s code, I put the ScaleName enum type declaration inside Listing 9-1. That was fine until I wrote the UseTemperature class (Listing 9-3). The
UseTemperature class refers to ScaleName. So in order to get at this ScaleName thing that I’d tucked inside Listing 9-1, I had to put some long, cumbersome statements in Listing 9-3:

```java
temp.setScale(Temperature.ScaleName.fahrenheit);
...
temp = new Temperature(Temperature.ScaleName.celsius);
...
temp = new Temperature(2.73, Temperature.ScaleName.kelvin);
```

At this point, a little voice told me that it was easier to put the ScaleName enum declaration in a file all its own. That way, both the Temperature and UseTemperature classes could refer to ScaleName without any extra chains full of names and dots.

**Some things never change**

Chapter 7 introduces the printf method, and explains that each printf call starts with a format string. The format string describes the way in which the other parameters are to be displayed.

In previous examples, this format string is always a quoted literal. For instance, the first printf call in Listing 7-7 is

```java
out.printf("$%4.2f\n", myInterest);
```

In Listing 9-3, I break with tradition and begin the printf call with a variable that I name format.

```java
out.printf(format, temp.getNumber(), temp.getScale());
```

That’s okay as long as my format variable is of type String. And indeed, in Listing 9-3, the first variable declaration is

```java
final String format = "%5.2f degrees %s\n";
```

In this declaration of the format variable, take special note of the word final. This Java keyword indicates that the value of format can’t be changed. If I add an additional assignment statement to Listing 9-3

```java
format = "%6.2f (%s)\n";
```

then the compiler barks back at me with a cannot assign a value to final variable message.
When I write the code in Listing 9-3, the use of the `final` keyword isn’t absolutely necessary. But the `final` keyword provides some extra protection. When I initialize `format` to "%5.2f degrees %s\n", I intend to use this same `format` just as it is, over and over again. I know darn well that I don’t intend to change the `format` variable’s value. Of course, in a 10,000-line program, I can become confused and try to assign a new value to `format` somewhere deep down in the code. So to prevent me from accidentally changing the `format` string, I declare the `format` variable to be final. It’s just good, safe programming practice.

More Subclasses (Doing Something about the Weather)

In Chapter 8, I make a big fuss over the notion of subclasses. That’s the right thing to do. Subclasses make code reusable, and reusable code is good code. With that in mind, it’s time to create a subclass of the `Temperature` class (which I develop in this chapter’s first section).

Building better temperatures

After perusing the code in Listing 9-3, you decide that the responsibility for displaying temperatures has been seriously misplaced. Listing 9-3 has several tedious repetitions of the lines to print temperature values. A 1970s programmer would tell you to collect those lines into one place and turn them into a method. (The 1970s programmer wouldn’t have used the word `method`, but that’s not important right now.) Collecting lines into methods is fine, but with today’s object-oriented programming methodology, you think in broader terms. Why not get each `temperature` object to take responsibility for displaying itself? After all, if you develop a `display` method, you’ll probably want to share the method with other people who use temperatures. So put the method right inside the declaration of a `temperature` object. That way, anyone who uses the code for temperatures has easy access to your `display` method.

Now replay the tape from Chapter 8. “Blah, blah, blah . . . don’t want to modify existing code . . . blah, blah, blah . . . too costly to start again from scratch . . . blah, blah, blah . . . extend existing functionality.” It all adds up to one thing:

Don’t abuse it. Instead, reuse it.
So you decide to create a subclass of the `Temperature` class, which is defined in Listing 9-1. Your new subclass will complement the `Temperature` class’s functionality by having methods to display values in a nice, uniform fashion. The new class, `TemperatureNice`, is shown in Listing 9-5.

**Listing 9-5: The TemperatureNice Class**

```java
import static java.lang.System.out;

class TemperatureNice extends Temperature {

    public TemperatureNice() {
        super();
    }

    public TemperatureNice(double number) {
        super(number);
    }

    public TemperatureNice(ScaleName scale) {
        super(scale);
    }

    public TemperatureNice(double number, ScaleName scale) {
        super(number, scale);
    }

    public void display() {
        out.printf("%5.2f degrees %s\n",
                getNumber(), getScale());
    }
}
```

In the `display` method of Listing 9-5, notice the calls to the `Temperature` class’s `getNumber` and `getScale` methods. Why do I need to do this? Well, inside the `TemperatureNice` class’s code, any direct references to the `number` and `scale` variables would generate error messages. It’s true that every `TemperatureNice` object has its own `number` and `scale` variables. (After all, `TemperatureNice` is a subclass of the `Temperature` class, and the code for the `Temperature` class defines the `number` and `scale` variables.) But because `number` and `scale` are declared to be private inside the `Temperature` class, only code that’s right inside the `Temperature` class can directly use these variables.

Don’t put additional declarations of the `number` and `scale` variables inside the `TemperatureNice` class’s code. If you do, you’ll inadvertently create four different variables (two called `number`, and another two called `scale`). You’ll assign values to one pair of variables. Then you’ll be shocked that when displaying the other pair of variables, those values seem to have disappeared.
When an object’s code contains a call to one of the object’s own methods, you don’t need to preface the call with a dot. For instance, in the last statement of Listing 9-5, the object calls its own methods with `getNumber()` and `getScale()`, not with `someObject.getNumber()` and `somethingOrOther.getScale()`. If going dotless makes you queasy, you can compensate by taking advantage of yet another use for the `this` keyword. Just write `this.getNumber()` and `this.getScale()` in the last line of Listing 9-5.

**Constructors for subclasses**

By far, the biggest news in Listing 9-5 is the way the code declares constructors. The `TemperatureNice` class has four of its own constructors. If you’ve gotten in gear thinking about subclass inheritance, you’ll wonder why these constructor declarations are necessary. Doesn’t `TemperatureNice` inherit the parent `Temperature` class’s constructors? No, subclasses don’t inherit constructors.

Subclasses don’t inherit constructors.

That’s right. Subclasses don’t inherit constructors. In one oddball case, a constructor may look like it’s being inherited, but that oddball situation is a fluke, not the norm. In general, when you define a subclass, you need to declare new constructors to go with the subclass.

I describe the oddball case (in which a constructor looks like it’s being inherited) later in this chapter, in the section “The default constructor.”

So the code in Listing 9-5 has four constructors. Each constructor has the name `TemperatureNice`, and each constructor has its own, uniquely identifiable parameter list. That’s the boring part. The interesting part is that each constructor makes a call to something named `super`, which is a Java keyword.

In Listing 9-5, `super` stands for a constructor in the parent class.

- The statement `super()` in Listing 9-5 calls the parameterless `Temperature()` constructor that’s in Listing 9-1. That parameterless constructor assigns `0.0` to the `number` variable and `ScaleName.fahrenheit` to the `scale` variable.

- The statement `super(number, scale)` in Listing 9-5 calls the constructor `Temperature(double number, ScaleName scale)` that’s in Listing 9-1. In turn, the constructor assigns values to the `number` and `scale` variables.

- In a similar way, the statements `super(number)` and `super(scale)` in Listing 9-5 call constructors from Listing 9-1.
The computer decides which of the Temperature class’s constructors is being called by looking at the parameter list after the word super. For instance, when the computer executes

```java
super(number, scale);
```

from Listing 9-5, the computer says to itself, “The number and scale variables in parentheses have types double and ScaleName. But only one of the Temperature constructors in Listing 9-1 has two parameters with types double and ScaleName. The constructor’s header looks like this:

```java
public Temperature(double number, ScaleName scale)
```

So, I guess I’ll execute the statements inside that particular constructor.”

## Using all this stuff

In Listing 9-5, I define what it means to be in the TemperatureNice class. Now it’s time to put this TemperatureNice class to good use. Listing 9-6 has code that uses TemperatureNice.

### Listing 9-6: Using the TemperatureNice Class

```java
class UseTemperatureNice {
    public static void main(String args[]) {
        TemperatureNice temp = new TemperatureNice();
        temp.setNumber(70.0);
        temp.setScale(ScaleName.fahrenheit);
        temp.display();

        temp = new TemperatureNice(32.0);
        temp.display();

        temp = new TemperatureNice(ScaleName.celsius);
        temp.display();

        temp = new TemperatureNice(2.73, ScaleName.kelvin);
        temp.display();
    }
}
```

The code in Listing 9-6 is very much like its cousin code in Listing 9-3. The big differences are as follows:
Listing 9-6 creates instances of the TemperatureNice class. That is, Listing 9-6 calls constructors from the TemperatureNice class, not the Temperature class.

Listing 9-6 takes advantage of the display method in the TemperatureNice class. So the code in Listing 9-6 is much more tidy than its counterpart in Listing 9-3.

A run of Listing 9-6 looks exactly like a run of the code in Listing 9-3. The run is shown previously in Figure 9-1.

**The default constructor**

The main message in the previous section is that subclasses don’t inherit constructors. So what gives with all the listings back in Chapter 8? In Listing 8-6, a statement says

```java
FullTimeEmployee ftEmployee = new FullTimeEmployee();
```

But, here’s the problem: The code defining FullTimeEmployee (Listing 8-3) doesn’t seem to have any constructors declared inside it. So, in Listing 8-6, how can you possibly call the FullTimeEmployee constructor?

Here’s what’s going on. When you create a subclass and don’t put any explicit constructor declarations in your code, then Java creates one constructor for you. It’s called a default constructor. If you’re creating the public FullTimeEmployee subclass, the default constructor looks like the one in Listing 9-7.

**Listing 9-7: A Default Constructor**

```java
public FullTimeEmployee() {
    super();
}
```

The constructor in Listing 9-7 takes no parameters, and its one statement calls the constructor of whatever class you’re extending. (Woe be to you if the class that you’re extending doesn’t have a parameterless constructor.)

You’ve just read about default constructors, but watch out! Notice one thing that this talk about default constructors doesn’t say: It doesn’t say that you always get a default constructor. In particular, if you create a subclass and define any constructors yourself, Java doesn’t add a default constructor for the subclass (and the subclass doesn’t inherit any constructors, either).
So how can this trip you up? Listing 9-8 has a copy of the code from Listing 8-3, but with one constructor added to it. Take a look at this modified version of the `FullTimeEmployee` code.

**Listing 9-8: Look, I Have a Constructor!**

```java
class FullTimeEmployee extends Employee {
    private double weeklySalary;
    private double benefitDeduction;

    public FullTimeEmployee(double weeklySalary) {
        this.weeklySalary = weeklySalary;
    }

    public void setWeeklySalary(double weeklySalaryIn) {
        weeklySalary = weeklySalaryIn;
    }

    public double getWeeklySalary() {
        return weeklySalary;
    }

    public void setBenefitDeduction(double benefitDedIn) {
        benefitDeduction = benefitDedIn;
    }

    public double getBenefitDeduction() { ....
}
```

Using the `FullTimeEmployee` code in Listing 9-8, a line like the following doesn’t work:

```java
FullTimeEmployee ftEmployee = new FullTimeEmployee();
```

It doesn’t work because, having declared a `FullTimeEmployee` constructor that takes one `double` parameter, you no longer get a default parameterless constructor for free.

So what do you do about this? If you need to declare any constructors, declare all the constructors that you’re possibly going to need. Take the constructor in Listing 9-7 and add it to the code in Listing 9-8. Then the call `new FullTimeEmployee()` starts working again.
An invisible constructor call

Here’s a program that I like to yank out and show people at Java parties. (Believe me, it surprises some of the veteran Java programmers.) The program is in Listings 9-9, 9-10, and 9-11.

Listing 9-9: First Class Accomodations

class MyClass {
    MyClass() {
        System.out.println
        ("MyClass constructor being called.");
    }
}

Listing 9-10: Second Class Accomodations

class MySubclass extends MyClass {
    MySubclass() {
        System.out.println
        ("MySubclass constructor being called.");
    }
}

Listing 9-11: What’s My Output?

class UseMyClasses {
    public static void main(String args[]) {
        new MySubclass();
    }
}

So what’s the output when you run the code in Listing 9-11? Huh? You think you get just one line of output? Sorry, that’s not the way it works. The output that you get is shown in Figure 9-3.

Figure 9-3: Surprise!

---
Configuration: Li
MyClass constructor being called.
MySubclass constructor being called.
Process completed.
Under certain circumstances, Java automatically adds an invisible call to `super`, which is at the top of a constructor body. It’s as if the `MySubclass` constructor in Listing 9-10 really looks like this:

```java
MySubclass() {
    super();
    System.out.println("MySubclass constructor being called.");
}
```

In Listing 9-10, the invisible `super` call fires up the `MyClass` constructor, which prints the message `MyClass constructor being called`. This automatic addition of a `super` call is a tricky bit of business that doesn’t appear often, so when it does appear, it may seem quite mysterious.

**A Constructor That Does More**

Here’s a quote from someplace near the start of this chapter: “And what if you’re interested in doing more than filling variables? Perhaps, when the computer creates a new object, you have a whole list of jobs for the computer to carry out.” Okay, what if?

This section’s example has a constructor that does more than just assign values to variables. The example is in Listings 9-12 and 9-13. The result of running the example’s code is shown in Figure 9-4.

**Listing 9-12: Defining a Frame**

```java
import java.awt.FlowLayout;
import javax.swing.JFrame;
import javax.swing.JButton;

class SimpleFrame extends JFrame {
    public SimpleFrame() {
        setTitle("Don't click the button!");
        setDefaultCloseOperation(EXIT_ON_CLOSE);
        add(new JButton("Panic"));
        setSize(300,100);
        setVisible(true);
    }
}
```
Listing 9-13: Displaying a Frame

class ShowAFrame {
    public static void main(String args[]) {
        new SimpleFrame();
    }
}

The code in Listing 9-12 is made up mostly of calls to Java API (Application Programming Interface) methods. What this means to you is that the code contains lots of names that are probably unfamiliar to you. When I was first becoming acquainted with Java, I foolishly believed that knowing Java meant knowing all these names. Quite the contrary: These names are just carry-on baggage. The real Java is the way the language implements object-oriented concepts.

Anyway, the code’s anorexic main method has only one statement — a call to the constructor in the SimpleFrame class. Notice how the object that this call creates isn’t even assigned to a variable. That’s okay, because the code doesn’t need to refer to the object anywhere else.

Up in the SimpleFrame class is only one constructor declaration. Far from just setting variables’ values, this constructor calls method after method from the Java API.

All the methods called in the SimpleFrame class’s constructor come from the parent class, JFrame. The JFrame class lives in the javax.swing package. This package and another package, java.awt, have classes that help you put windows, images, drawings, and other gizmos on a computer screen. (In the java.awt package, the letters awt stand for abstract windowing toolkit.)

For a little gossip about the notion of a Java package, see the sidebar entitled “Packages and import declarations.” For lots of gossip about the notion of a Java package, see Appendix B and (on the CD-ROM) Chapter 15.

In the Java API, what people normally call a window is an instance of the javax.swing.JFrame class.
Looking at Figure 9-4, you can probably tell that an instance of the `SimpleFrame` class doesn’t do much. The frame has only one button and, when you click the button, nothing happens. I made the frame this way to keep the example from becoming too complicated. Even so, the code in Listing 9-12 uses several API classes and methods. The `setTitle`, `setLayout`, `setDefaultCloseOperation`, `add`, `setSize`, and `setVisible` methods all belong to the `javax.swing.JFrame` class. Here’s a list of names used in the code:

```
import java.util.Scanner;
import javax.swing.*;
```

A class’s fully qualified name includes the name of the package in which the class is defined. (You can find out all this stuff about `java.util` and `Scanner` by reading Java’s API documentation. For tips on reading the documentation, see Chapter 3 and this book’s Web site.)

Here’s another example. The declaration

```
import javax.swing.*;
```

is valid because `javax.swing` is the name of a package in the Java API, and the asterisk refers to all classes in the `javax.swing` package. With this import declaration at the top of your Java code, you can use abbreviated names for classes in the `javax.swing` package — names like `JFrame`, `JButton`, `JMenuBar`, `JCheckBox`, and many others.

Here’s one more example. A line like

```
import javax.*;  //Bad!!
```

is not a valid import declaration. The Java API has no package with the one-word name `javax`. You may think that this line allows you to abbreviate all names beginning with `javax` (names like `javax.swing.JFrame` and `javax.sound.midi`), but that’s not the way the import declaration works. Because `javax` isn’t the name of a package, the line `import javax.*` just angers the Java compiler.

Packages and import declarations

Java has a feature that lets you lump classes into groups of classes. Each lump of classes is called a package. In the Java world, programmers customarily give these packages long, dot-filled names. For instance, because I’ve registered the domain name `burdbrain.com`, I may name a package `com.burdbrain.utils.textUtils`. The Java API is actually a big collection of packages. The API has packages with names like `java.lang`, `java.util`, `java.awt`, `javax.swing`, and so on.

With this information about packages, I can clear up some of the confusion about import declarations. Any import declaration that doesn’t use the word `static` must start with the name of a package and must end with either of the following:

- The name of a class within that package
- An asterisk (indicating all classes within that package)

For example, the declaration

```
import java.util.Scanner;
```

is valid because `java.util` is the name of a package in the Java API, and `Scanner` is the name of a class in the `java.util` package. The dotted name `java.util.Scanner` is the fully qualified name of the `Scanner` class.

Looking at Figure 9-4, you can probably tell that an instance of the `SimpleFrame` class doesn’t do much. The frame has only one button and, when you click the button, nothing happens. I made the frame this way to keep the example from becoming too complicated. Even so, the code in Listing 9-12 uses several API classes and methods. The `setTitle`, `setLayout`, `setDefaultCloseOperation`, `add`, `setSize`, and `setVisible` methods all belong to the `javax.swing.JFrame` class. Here’s a list of names used in the code:
setTitle: Calling setTitle puts words in the frame’s title bar. (The new SimpleFrame object is calling its own setTitle method.)

FlowLayout: An instance of the FlowLayout class positions objects on the frame in centered, typewriter fashion. Because the frame in Figure 9-4 has only one button on it, that button is centered near the top of the frame. If the frame had eight buttons, five of them may be lined up in a row across the top of the frame, and the remaining three would be centered along a second row.

setLayout: Calling setLayout puts the new FlowLayout object in charge of arranging components, such as buttons, on the frame. (The new SimpleFrame object is calling its own setLayout method.)

setDefaultCloseOperation: Calling setDefaultCloseOperation tells Java what to do when you click the little × in the frame’s upper-right corner. Without this method call, the frame itself disappears, but the Java Virtual Machine (JVM) keeps running. If you use JCreator, you have to halt the JVM by choosing Tools ► Stop Tool.

Calling setDefaultCloseOperation(EXIT_ON_CLOSE) tells Java to shut itself down when you click the × in the frame’s upper-right corner. The alternatives to EXIT_ON_CLOSE are HIDE_ON_CLOSE, DISPOSE_ON_CLOSE, and my personal favorite, DO NOTHING_ON_CLOSE.

JButton: The JButton class lives in the javax.swing package. One of the class’s constructors takes a String instance (such as "Panic") for its parameter. Calling this constructor makes that String instance into the label on the face of the new button.

add: The new SimpleFrame object calls its add method. Calling the add method places the button on the object’s surface (in this case, the surface of the frame).

setSize: The frame becomes 300 pixels wide and 100 pixels tall. (In the javax.swing package, whenever you specify two dimension numbers, the width number always comes before the height number.)

setVisible: When it’s first created, a new frame is invisible. But when the new frame calls setVisible(true), the frame appears on your computer screen.
"I asked for software that would biodegrade after it was thrown out, not while it was running."
In this part . . .

Here’s where I start sharing some big-time Java concepts. This part of the book describes the tricky things, the little nooks and crannies, the special rules, and the not-so-special exceptions. As usual, you shouldn’t feel intimidated. I take you one step at a time and keep the whole thing light, interesting, and manageable.
Hello, again. You’re listening to radio station WWW, and I’m your host, Sam Burd. It’s the start again of the big baseball season, and today station WWW brought you live coverage of the Hankees versus Socks game. At this moment, I’m awaiting news of the game’s final score.

If you remember from earlier this afternoon, the Socks looked like they were going to take those Hankees to the cleaners. Then, the Hankees were belting ball after ball, giving the Socks a run for their money. Those Socks! I’m glad I wasn’t in their shoes.

Anyway, as the game went on, the Socks pulled themselves up. Now the Socks are nose to nose with the Hankees. We’ll get the final score in a minute, but first, a few reminders. Stay tuned after this broadcast for the big Jersey’s game. And don’t forget to tune in next week when the Cleveland Gowns play the Bermuda Shorts.

Okay, here’s the final score. Which team has the upper hand? Which team will come out a head? And the winner is . . . oh, no! It’s a tie!
Defining a Class (What It Means to Be a Baseball Player)

As far as I’m concerned, a baseball player has a name and a batting average. Listing 10-1 puts my feeling about this into Java program form.

Listing 10-1: The Player Class

```java
import java.text.DecimalFormat;

class Player {
    private String name;
    private double average;

    public Player(String name, double average) {
        this.name = name;
        this.average = average;
    }

    public String getName() {
        return name;
    }

    public double getAverage() {
        return average;
    }

    public String getAverageString() {
        DecimalFormat decFormat =
            new DecimalFormat("    .000");
        return decFormat.format(average);
    }
}
```

So here I go, picking apart the code in Listing 10-1. Luckily, earlier chapters cover lots of stuff in this code. The code defines what it means to be an instance of the Player class. Here’s what’s in the code:

- **Declarations of the variables** name and average. For bedtime reading about variable declarations, see Chapter 4.

- **A constructor to make new instances of the Player class.** For the low-down on constructors, see Chapter 9.
 Getter methods for the variables name and average. For chitchat about accessor methods (that is, setter and getter methods), see Chapter 7.

 A method that returns the player’s batting average in String form. For the good word about methods, see Chapter 7.

Another way to beautify your numbers

The last method in Listing 10-1 takes the value from the average variable (a player’s batting average), converts that value (normally of type double) into a String, and then sends that String value right back to the method caller. The use of DecimalFormat, which comes right from the Java API (Application Programming Interface), makes sure that the String value looks like a baseball player’s batting average. That is, the String value starts with lots of blank spaces, has no digits to the left of the decimal point, and has exactly three digits to the right of the decimal point. (The blank spaces ensure that a gap exists between the batting average and whatever text appears before it.)

Java’s DecimalFormat class can be quite handy. For example, to display the values 345 and -345 with an accounting-friendly format, you can use the following code:

```java
DecimalFormat decFormat =
    new DecimalFormat("$###0.00;($###0.00)");
System.out.println(decFormat.format(345));
System.out.println(decFormat.format(-345));
```

In this little example’s format string, everything before the semicolon dictates the way positive numbers are displayed, and everything after the semicolon determines the way negative numbers are displayed. So with this format, the numbers 345 and -345 appear as follows:

```
$345.00
($345.00)
```

To discover some other tricks with numbers, visit the DecimalFormat page of Java’s API documentation.

Using the Player class

Listings 10-2 and 10-3 have code that uses the Player class — the class that’s defined way back in Listing 10-1.
Listing 10-2: Using the Player Class

```java
import java.util.Scanner;
import java.io.File;
import java.io.IOException;
import javax.swing.JFrame;
import javax.swing.JLabel;
import java.awt.GridLayout;

class TeamFrame extends JFrame {
    public TeamFrame() throws IOException {
        Player player;
        Scanner myScanner =
            new Scanner(new File("Hankees.txt"));

        for (int num = 1; num <= 9; num++) {
            player =
                new Player(myScanner.nextLine(),
                myScanner.nextDouble());
            myScanner.nextLine();
            addPlayerInfo(player);
        }
        setTitle("The Hankees");
        setLayout(new GridLayout(9,2));
        setDefaultCloseOperation(EXIT_ON_CLOSE);
        pack();
        setVisible(true);
    }

    void addPlayerInfo(Player player) {
        add(new JLabel(player.getName()));
        add(new JLabel(player.getAverageString()));
    }
}
```

Listing 10-3: Displaying a Frame

```java
import java.io.IOException;

class ShowTeamFrame {
    public static void main(String args[]) throws IOException {
        new TeamFrame();
    }
}
```
For a run of the code in Listings 10-1, 10-2, and 10-3, see Figure 10-1. To run this program yourself, you need the Hankees.txt file. (The file is loaded automatically onto your hard drive when you install JCreator from this book’s CD-ROM.) This file contains data on your favorite baseball players. (See Figure 10-2.)

For this section’s code to work correctly, you must have a line break after the last .212 in Figure 10-2. For details about line breaks, see Chapter 8.

**Nine, count ’em, nine**

The code in Listing 10-2 calls the Player constructor nine times. This means that the code creates nine instances of the Player class. Each instance has its own name and average variables. Each instance also has its own Player constructor and its own getName, getAverage, and getAverageString methods. Look at Figure 10-3 and think of the Player class with its nine incarnations.
Don't get all GUI on me

The code in Listing 10-2 uses several names from the Java API. Some of these names are explained in Chapter 9. Others are explained right here:

- **JLabel**: A JLabel is an object with some text in it. One of the ways to display text inside the frame is to add an instance of the JLabel class to the frame.

  In Listing 10-2, the addPlayerInfo method is called nine times, once for each player on the team. Each time addPlayerInfo is called, the method adds two new JLabel objects to the frame. The text for each JLabel object comes from a player object’s getter method.

- **GridLayout**: A GridLayout arranges things in evenly spaced rows and columns. This constructor for the GridLayout class takes two parameters — the number of rows and the number of columns.

  In Listing 10-2, the call to the GridLayout constructor takes parameters (9, 2). So in Figure 10-1, the display has nine rows (one for each player) and two columns (one for a name, and another for an average).

- **pack**: When you pack a frame, you set the frame’s size. That’s the size the frame has when it appears on your computer screen. Packing a frame shrink-wraps the frame around whatever objects you’ve added inside the frame.

  In Listing 10-2, by the time you’ve reached the call to pack, you’ve already called addPlayerInfo nine times and added 18 labels to the frame. In executing the pack method, the computer picks a nice size for each label, given whatever text you’ve put inside the label. Then, the computer picks a nice size for the whole frame, given that the frame has these 18 labels inside it.

When you plop stuff onto frames, you have quite a bit of leeway with the order in which you do things. For instance, you can set the layout before or after you’ve added labels and other stuff to the frame. If you call setLayout
and then add labels, the labels appear in nice, orderly positions on the frame. If you reverse this order (add labels and then call `setLayout`), the calling of `setLayout` rearranges the labels in a nice, orderly fashion. It works fine either way.

In setting up a frame, the one thing that you shouldn’t do is violate the following sequence:

```
Add things to the frame, then
pack();
setVisible(true);
```

If you call `pack` and then add more things to the frame, the `pack` method doesn’t take the more recent things that you’ve added into consideration. If you call `setVisible` before you add things or call `pack`, the user sees the frame as it’s being constructed. Finally, if you forget to set the frame’s size (by calling `pack` or some other sizing method), the frame that you see looks like the one in Figure 10-4. (Normally, I wouldn’t show you an anomalous run like the one in Figure 10-4, but I’ve made the mistake so many times that I feel as if this puny frame is an old friend of mine.)

**Figure 10-4:** An undernourished frame.

---

**Tossing an exception from method to method**

Chapter 8 introduces input from a disk file, and along with that topic comes the notion of an exception. When you tinker with a disk file, you need to acknowledge the possibility of raising an `IOException`. That’s the lesson from Chapter 8, and that’s why the constructor in Listing 10-2 has a `throws IOException` clause.

But what about the `main` method in Listing 10-3? With no apparent reference to disk files in this `main` method, why does the method need its own `throws IOException` clause? Well, an exception is a hot potato. If you have one, you have to either eat it (as you can see in Chapter 12) or use a `throws` clause to toss it to someone else. If you toss an exception with a `throws` clause, someone else is stuck with the exception just the way you were.
The constructor in Listing 10-2 throws an IOException, but to whom is this exception thrown? Who in this chain of code becomes the bearer of responsibility for the problematic IOException? Well, who called the constructor in Listing 10-2? It was the main method in Listing 10-3 — that’s who called the TeamFrame constructor. Because the TeamFrame constructor throws its hot potato to the main method in Listing 10-3, the main method has to deal with it. As shown in Listing 10-3, the main method deals with it by tossing the IOException again (by having a throws IOException clause of its own). That’s how the throws clause works in Java programs.

If a method calls another method, and the called method has a throws clause, the calling method must contain code that deals with the exception. To find out more about dealing with exceptions, read Chapter 12.

At this point in the book, the astute For Dummies reader may pose a follow-up question or two. “When a main method has a throws clause, someone else has to deal with the exception in that throws clause. But who called the main method? Who deals with the IOException in the throws clause of Listing 10-3?” The answer is that the Java Virtual Machine (or JVM, the thing that runs all your Java code) called the main method. So the JVM takes care of the IOException in Listing 10-3. If the program has any trouble reading the Hankees.txt file, the responsibility ultimately falls on the JVM. The JVM takes care of things by displaying an error message and then ending the run of your program. How convenient!

Making Static (Finding the Team Average)

Thinking about the code in Listings 10-1 through 10-3, you decide that you’d like to find the team’s overall batting average. Not a bad idea! The Hankees in Figure 10-1 have an average of about .106, so the team needs some intensive training. While the players are out practicing on the ball field, you have a philosophical hurdle to overcome.

In Listings 10-1 through 10-3, you have three classes: a Player class and two other classes that help display data from the Player class. So in this class morass, where do the variables storing your overall, team-average tally go?

It makes no sense to put tally variables in either of the displaying classes (TeamFrame and ShowTeamFrame). After all, the tally has something or other to do with players, teams, and baseball. The displaying classes are about creating windows, not about playing baseball.
You’re uncomfortable putting an overall team average in an instance of the Player class because an instance of the Player class represents just one player on the team. What business does a single player have storing overall team data? Sure, you could make the code work, but it wouldn’t be an elegant solution to the problem.

Finally, you discover the keyword static. Anything that’s declared to be static belongs to the whole class, not to any particular instance of the class. When you create the static variable totalOfAverages, you create just one copy of the variable. This copy stays with the entire Players class. No matter how many instances of the Player class you create — one, nine, or none — you have just one totalOfAverages variable. And, while you’re at it, you create other static variables (playerCount and decFormat) and static methods (findTeamAverage and findTeamAverageString). To see what I mean, look at Figure 10-5.

Figure 10-5: Some static and non-static variables and methods.

Going along with your passion for subclasses, you put code for team-wide tallies in a subclass of the Player class. The code is shown in Listing 10-4.

Listing 10-4: Creating a Team Batting Average

```java
import java.text.DecimalFormat;

class PlayerPlus extends Player {
    private static int playerCount = 0;
    private static double totalOfAverages = .000;
    private static DecimalFormat decFormat =
        new DecimalFormat("    .000");
```

(continued)
public PlayerPlus(String name, double average) {
    super(name, average);
    playerCount++;
    totalOfAverages += average;
}

public static double findTeamAverage() {
    return totalOfAverages / playerCount;
}

public static String findTeamAverageString() {
    return decFormat.format
        (totalOfAverages / playerCount);
}

Why is there so much static?

Maybe you’ve noticed — the code in Listing 10-4 is overflowing with the word static. That’s because nearly everything in this code belongs to the entire PlayerPlus class and not to individual instances of the class. That’s good because something like playerCount (the number of players on the team) shouldn’t belong to individual players, and having each PlayerPlus object keep track of its own count would be silly. (“I know how many players I am. I’m just one player!”) If you had nine individual playerCount variables, either each variable would store the number 1 (which is useless) or you would have nine different copies of the count, which is wasteful and prone to error. So by making playerCount static, you’re keeping the playerCount in just one place, where it belongs.

The same kind of reasoning holds for the totalOfAverages. Eventually, the totalOfAverages variable will store the sum of the players’ batting averages. For all nine members of the Hankees, this adds up to .956. It’s not until someone calls the findTeamAverage or findTeamAverageString method that the computer actually finds the overall Hankee team batting average.

You also want the methods findTeamAverage and findTeamAverageString to be static. Without the word static, there would be nine findTeamAverage methods — one for each instance of the PlayerPlus class. This wouldn’t make much sense. Each instance would have the code to calculate totalOfAverages/playerCount on its own, and each of the nine calculations would yield the very same answer.

In general, any task that all the instances have in common (and that yields the same result for each instance) should be coded as a static method.
Constructors are never static.

In Listing 10-4, the decFormat variable is static. This makes sense, because decFormat makes totalOfAverages / playerCount look nice, and both variables in the expression totalOfAverages / playerCount are static. Thinking more directly, the code needs only one thing for formatting numbers. If you have several numbers to format, the same decFormat thing that belongs to the entire class can format each number. Creating a decFormat for each player is not only inelegant, but also wasteful.

In this book, my first serious use of the word static is way back in Listing 3-1. I use the static keyword as part of every main method (and lots of main methods are in this book’s listings). So why does main have to be static? Well, remember that non-static things belong to objects, not classes. If the main method isn’t static, you can’t have a main method until you create an object. But, when you start up a Java program, no objects have been created yet. The statements that are executed in the main method start creating objects. So, if the main method isn’t static, you have a big chicken-and-egg problem.

Displaying the overall team average

You may be noticing a pattern. When you create code for a class, you generally write two pieces of code. One piece of code defines the class, and the other piece of code uses the class. (The ways to use a class include calling the class’s constructor, referencing the class’s nonprivate variables, calling the class’s methods, and so on.) Listing 10-4, shown previously, contains code that defines the PlayerPlus class, and Listing 10-5 contains code that uses this PlayerPlus class.

Listing 10-5: Using the Code from Listing 10-4

```java
import java.util.Scanner;
import java.io.File;
import java.io.IOException;
import javax.swing.JFrame;
import javax.swing.JLabel;
import java.awt.GridLayout;

class TeamFrame extends JFrame {
    public TeamFrame() throws IOException {
        PlayerPlus player;
        Scanner myScanner =
            new Scanner(new File("Hankees.txt"));
    }

    // (continued)
```
Listing 10-5 (continued)

for (int num = 1; num <= 9; num++) {
    player =
    new PlayerPlus(myScanner.nextLine(),
                    myScanner.nextDouble());
    myScanner.nextLine();
    addPlayerInfo(player);
}

add(new JLabel());
add(new JLabel("  
----
"));
add(new JLabel("Team Batting Average:"));
add(new JLabel(PlayerPlus.findTeamAverageString()));

setTitle("The Hankees");
setLayout(new GridLayout(11, 2));
setDefaultCloseOperation(EXIT_ON_CLOSE);
pack();
setVisible(true);
}

void addPlayerInfo(PlayerPlus player) {
    add(new JLabel(player.getName()));
    add(new JLabel(player.getAverageString()));
}

To run the code in Listing 10-5, you need a class with a main method. The
ShowTeamFrame class in Listing 10-3 works just fine. (If you run JCreator from
this book’s CD-ROM, you’re all set because the ShowTeamFrame.java file is
already in a project along with Listing 10-5.)

Figure 10-6 shows a run of the code from Listing 10-5. This run depends
on the availability of the Hankees.txt file from Figure 10-2. The code in
Listing 10-5 is almost an exact copy of the code from Listing 10-2. (So close
is the copy that if I could afford it, I’d sue myself for theft of intellectual prop-
erty.) The only thing new in Listing 10-5 is the stuff shown in bold.
In Listing 10-5, the GridLayout has two extra rows: one row for spacing and another row for the Hankee team’s average. Each of these rows has two Label objects in it.

- **The spacing row has a blank label and a label with a dashed line.** The blank label is a placeholder. When you add components to a GridLayout, the components are added row by row, starting at the left end of a row and working toward the right end of the row. Without this blank label, the dashed line label would appear at the left end of the row, under Hugh R. DaReader’s name.

- **The other row has a label displaying the words Team Batting Average, and another label displaying the number .106.** The method call that gets the number .106 is interesting. The call looks like this:

  ```java
  PlayerPlus.findTeamAverageString()
  ```

  Take a look at that method call. That call has the following form:

  ```java
  ClassName.methodName()
  ```

  That’s new and different. In earlier chapters, I say that you normally preface a method call with an object’s name, not a class’s name. So why do I use a class name here? The answer: When you call a static method, you preface the method’s name with the name of the class that contains the method. The same holds true whenever you reference another class’s static variable. This makes sense. Remember, the whole class that defines a static variable or method owns that variable or method. So, to refer to a static variable or method, you preface the variable or method’s name with the class’s name.

When you’re referring to a static variable or method, you can cheat and use an object’s name in place of the class name. For instance, in Listing 10-5, with judicious rearranging of some other statements, you can use the expression `player.findTeamAverageString()`.

Java has a neat feature called the static initializer. Using this feature, you can execute statements involving static variables before calling any of the class’s methods. To find out more about static initializers, visit this book’s Web site.

### Static is old hat

This section makes a big noise about static variables and methods, but static things have been part of the picture since early in this book. For example, Chapter 3 introduces System.out.println. The name System refers to a class, and out is a static variable in that class. That’s why, in Chapter 4 and beyond, I use the static keyword to import the out variable:
In Java, static variables and methods show up all over the place. When they’re declared in someone else’s code, and you’re making use of them in your code, you hardly ever have to worry about them. But when you’re declaring your own variables and methods and must decide whether to make them static, you have to think a little harder.

Could cause static; handle with care

When I first started writing Java, I had recurring dreams about getting a certain error message. The message was non-static variable or method cannot be referenced from a static context. So often did I see this message, so thoroughly was I perplexed, that the memory of this message became burned into my subconscious existence.

These days, I know why I get the error message so often. I can even make the message occur if I want. But I still feel a little shiver whenever I see this message on my screen.

Before you can understand why the message occurs and how to fix the problem, you need to get some terminology under your belt. If a variable or method isn’t static, it’s called non-static. (Real surprising, hey?) Given that terminology, there are at least two ways to make the dreaded message appear:

- Put Class.nonstaticThing somewhere in your program.
- Put nonstaticThing somewhere inside a static method.

In either case, you’re getting yourself into trouble. You’re taking something that belongs to an object (the non-static thing) and putting it in a place where no objects are in sight.

Take, for instance, the first of the two situations listed above. To see this calamity in action, go back to Listing 10-5. Toward the end of the listing, change player.getName() to Player.getName(). That does the trick. What could Player.getName possibly mean? If it meant anything, the expression Player.getName would mean “call the getName method that belongs to the entire Player class.” But look back at Listing 10-1. The getName method isn’t static. Each instance of the Player (or PlayerPlus) class has a getName method. None of the getName methods belong to the entire class. So the call Player.getName doesn’t make any sense. (Maybe the computer is pulling punches when it displays the inoffensive cannot be referenced... message. Perhaps a harsh nonsensical expression message would be more fitting.)
For a taste of the second situation (in the bullet list that I give earlier in this section), go back to Listing 10-4. While no one’s looking, quietly remove the word static from the declaration of the decFormat variable (near the top of the listing). This turns decFormat into a non-static variable. Suddenly, each player on the team has a separate decFormat variable.

Well, things are just hunky-dory until the computer reaches the findTeamAverageString method. That static method has four decFormat.SuchAndSuch statements in it. Once again, you’re forced to ask what a statement of this kind could possibly mean. Method findTeamAverageString belongs to no instance in particular. (The method is static, so the entire PlayerPlus class has one findTeamAverageString method.) But with the way you’ve just butchered the code, plain old decFormat, without reference to a particular object, has no meaning. So again, you’re referencing the non-static variable, decFormat, from inside a static method’s context. Shame!

Experiments with Variables

One summer during my college days, I was sitting on the front porch, loafing around, talking with someone I’d just met. I think her name was Janine. “Where are you from?” I asked. “Mars,” she answered. She paused to see whether I’d ask a follow-up question.

As it turned out, Janine was from Mars, Pennsylvania, a small town about 20 miles north of Pittsburgh. Okay, so what’s my point? The point is that the meaning of a name depends on the context. If you’re just north of Pittsburgh and ask, “How do I get to Mars from here?” you may get a sensible, nonchalant answer. But if you ask the same question standing on a street corner in Manhattan, you’ll probably arouse some suspicion. (Okay, knowing Manhattan, people would probably just ignore you.)

Of course, the people who live in Mars, Pennsylvania, are very much aware that their town has an oddball name. Fond memories of teenage years at Mars High School don’t prevent a person from knowing about the big red planet. On a clear evening in August, you can still have the following conversation with one of the local residents:

You: How do I get to Mars?
Local resident: You’re in Mars, pal. What particular part of Mars are you looking for?
You: No, I don’t mean Mars, Pennsylvania. I mean the planet Mars.
Local resident: Oh, the planet! Well, then, catch the 8:19 train leaving for Cape Canaveral . . . No, wait, that’s the local train. That’d take you through West Virginia . . .
So the meaning of a name depends on where you’re using the name. Although most English-speaking people think of Mars as a place with a carbon dioxide atmosphere, some folks in Pennsylvania think about all the shopping they can do in Mars. And those folks in Pennsylvania really have two meanings for the name Mars. In Java, those names may look like this: Mars and planets.Mars.

**Putting a variable in its place**

Your first experiment is shown in Listings 10-6 and 10-7. The listings’ code highlights the difference between variables that are declared inside and outside methods.

### Listing 10-6: Two Meanings for Mars

```java
import static java.lang.System.out;

class EnglishSpeakingWorld {
    String mars = "red planet";

    void visitPennsylvania() {
        out.println("visitPA is running:");

        String mars = "Janine's home town";

        out.println(mars);
        out.println(this.mars);
    }
}
```

### Listing 10-7: Calling the Code of Listing 10-6

```java
import static java.lang.System.out;

class GetGoing {
    public static void main(String args[]) {
        out.println("main is running:");

        EnglishSpeakingWorld e = new EnglishSpeakingWorld();

        //out.println(mars); cannot resolve symbol
        out.println(e.mars);
        e.visitPennsylvania();
    }
}
```
Figure 10-7 shows a run of the code in Listings 10-6 and 10-7. Figure 10-8 shows a diagram of the code’s structure. In the GetGoing class, the main method creates an instance of the EnglishSpeakingWorld class. The variable e refers to the new instance. The new instance is an object with a variable named mars inside it. That mars variable has value "red planet". The mars variable is called an *instance variable*, because the variable belongs to an object — an instance of the EnglishSpeakingWorld class.

Now look at the main method in Listing 10-7. Inside the GetGoing class’s main method, you aren’t permitted to write out.println(mars). In other words, a bare-faced reference to any mars variable is a definite no-no. The mars variable that I mention in the previous paragraph belongs to the EnglishSpeakingWorld object, not the GetGoing class.

However, inside the GetGoing class’s main method, you can certainly write e.mars because the e variable refers to your EnglishSpeakingWorld object. That’s nice.
Near the bottom of the code, the visitPennsylvania method is called. When you're inside visitPennsylvania, you have another declaration of a mars variable, whose value is "Janine's home town". This particular mars variable is called a method-local variable because it belongs to just one method — the visitPennsylvania method.

So now you have two variables, both with the name mars. One mars variable, an instance variable, has the value "red planet". The other mars variable, a method-local variable, has the value "Janine's home town". In the code, when you use the word mars, which of the two variables are you referring to?

The answer is, when you're visiting Pennsylvania, the variable with value "Janine's home town" wins. When in Pennsylvania, think the way the Pennsylvanians think. When you're executing code inside the visitPennsylvania method, resolve any variable name conflicts by going with variables that are declared right inside the visitPennsylvania method.

So what if you're in Pennsylvania and need to refer to that two-mooned celestial object? More precisely, how does code inside the visitPennsylvania method refer to the variable with value "red planet"? The answer is, use this.mars. The word this points to whatever object contains all this code (and not to any methods inside the code). That object, an instance of the EnglishSpeakingWorld class, has a big, fat mars variable, and that variable's value is "red planet". So that's how you can force code to see outside the method it's in — you use the Java keyword this.

For more information on the keyword this, see Chapter 9.

Telling a variable where to go

Years ago, when I lived in Milwaukee, Wisconsin, I made frequent use of the local bank's automatic teller machines. Machines of this kind were just beginning to become standardized. The local teller machine system was named TYME, which stood for Take Your Money Everywhere.

I remember traveling by car out to California. At one point, I got hungry and stopped for a meal, but I was out of cash. So I asked a gas station attendant, “Do you know where there's a TYME machine around here?”

So you see, a name that works well in one place could work terribly, or not at all, in another place. In Listings 10-8 and 10-9, I illustrate this point (with more than just an anecdote about teller machines).
Listing 10-8: Tale of Atomic City

```java
import static java.lang.System.out;

class EnglishSpeakingWorld2 {
    String mars;

    void visitIdaho() {
        out.println("visitID is running:");
        
        mars = "   red planet";
        String atomicCity = "   Population: 25";

        out.println(mars);
        out.println(atomicCity);
    }

    void visitNewJersey() {
        out.println("visitNJ is running:");

        out.println(mars);
        //out.println(atomicCity);
        //   cannot resolve symbol
    }
}
```

Listing 10-9: Calling the Code of Listing 10-8

```java
class GetGoing2 {
    public static void main(String args[]) {
        EnglishSpeakingWorld2 e = new EnglishSpeakingWorld2();

        e.visitIdaho();
        e.visitNewJersey();
    }
}
```

Figure 10-9 shows a run of the code in Listings 10-8 and 10-9. Figure 10-10 shows a diagram of the code's structure. The code for `EnglishSpeakingWorld2` has two variables. The `mars` variable, which isn’t declared inside a method, is an instance variable. The other variable, `atomicCity`, is a method-local variable and is declared inside the `visitIdaho` method.
In Listing 10-8, notice where each variable can and can’t be used. When you try to use the \texttt{atomicCity} variable inside the \texttt{visitNewJersey} method, you get an error message. Literally, the message says \texttt{cannot resolve symbol}. Figuratively, the message says, “Hey, buddy, Atomic City is in Idaho, not New Jersey.” Technically, the message says that the method-local variable \texttt{atomicCity} is available only in the \texttt{visitIdaho} method because that’s where the variable was declared.

So back inside the \texttt{visitIdaho} method, you’re free to use the \texttt{atomicCity} variable as much as you want. After all, the \texttt{atomicCity} variable is declared inside the \texttt{visitIdaho} method.

And what about Mars? Have you forgotten about your old friend, that lovely eighty-degrees-below-zero planet? Well, both the \texttt{visitIdaho} and \texttt{visitNewJersey} methods can access the \texttt{mars} variable. That’s because the \texttt{mars} variable is an instance variable. The \texttt{mars} variable is declared in the
code for the `EnglishSpeakingWorld2` class but not inside any particular method. (In my stories about the names for things, remember that people who live in both states, Idaho and New Jersey, have heard of the planet Mars.)

The lifecycle of the `mars` variable has three separate steps:

- When the `EnglishSpeakingWorld2` class first flashes into existence, the computer sees `String mars` and creates space for the variable.
- When the `visitIdaho` method is executed, the method assigns the value "red planet" to the `mars` variable. (The `visitIdaho` method also prints the value of the `mars` variable.)
- When the `visitNewJersey` method is executed, the method prints the `mars` value once again.

In this way, the `mars` variable’s value is passed from one method to another.

Passing Parameters

A method can communicate with another part of your Java program in several ways. One of the ways is through the method’s parameter list. Using a parameter list, you pass on-the-fly information to a method as the method is being called.

So imagine that the information you pass to the method is stored in one of your program’s variables. What, if anything, does the method actually do with that variable? This section presents a few interesting case studies.

Pass by value

According to my Web research, the town of Smackover, Arkansas, has 2,232 people in it. But my research isn’t current. Just yesterday, Dora Kermongoos celebrated a joyous occasion over at Smackover General Hospital — the birth of her healthy, blue-eyed baby girl. (The girl weighs 7 pounds, 4 ounces, and is 21 inches tall.) Now the town’s population has risen to 2,233.

Listing 10-10 has a very bad program in it. The program is supposed to add 1 to a variable that stores Smackover’s population, but the program doesn’t work. Take a look at Listing 10-10 and see why.
Listing 10-10: This Program Doesn’t Work

class TrackPopulation {
    public static void main(String args[]) {
        int smackoverARpop = 2232;

        birth(smackoverARpop);
        System.out.println(smackoverARpop);
    }

    static void birth(int cityPop) {
        cityPop++;
    }
}

When you run the program in Listing 10-10, the program displays the number 2,232 on-screen. After nine months of planning and anticipation and a whopping seven hours in labor, the Kermongoos family’s baby girl wasn’t registered in the system. What a shame!

The improper use of parameter passing caused the problem. In Java, when you pass a parameter that has one of the eight primitive types to a method, that parameter is passed by value.

For a review of Java’s eight primitive types, see Chapter 4.

Here’s what this means in plain English: Any changes that the method makes to the value of its parameter don’t affect the values of variables back in the calling code. In Listing 10-10, the birth method can apply the ++ operator to cityPop all it wants — the application of ++ to the cityPop parameter has absolutely no effect on the value of the smackoverARpop variable back in the main method.

Technically, what’s happening is the copying of a value. (See Figure 10-11.) When the main method calls the birth method, the value stored in smackoverARpop is copied to another memory location — a location reserved for the cityPop parameter’s value. During the birth method’s execution, 1 is added to the cityPop parameter. But the place where the original 2232 value was stored — the memory location for the smackoverARpop variable — remains unaffected.

When you do parameter passing with any of the eight primitive types, the computer uses pass by value. The value stored in the calling code’s variable remains unchanged. This happens even if the calling code’s variable and the called method’s parameter happen to have the exact same name.
Returning a result

You must fix the problem that the code in Listing 10-10 poses. After all, a young baby Kermongoos can’t go through life untracked. To record this baby’s existence, you have to add 1 to the value of the smackoverARpop variable. You can do this in plenty of ways, and the way presented in Listing 10-11 isn’t the simplest. Even so, the way shown in Listing 10-11 illustrates a point: Returning a value from a method call can be an acceptable alternative to parameter passing. Look at Listing 10-11 to see what I mean.

Listing 10-11: This Program Works

```java
class TrackPopulation2 {
    public static void main(String args[]) {
        int smackoverARpop = 2232;
        smackoverARpop = birth(smackoverARpop);
        System.out.println(smackoverARpop);
    }

    static int birth(int cityPop) {
        return cityPop + 1;
    }
}
```

After running the code in Listing 10-11, the number you see on your computer screen is the correct number, 2,233.
The code in Listing 10-11 has no new features in it (unless you call working correctly a new feature). The most important idea in Listing 10-11 is the return statement, which also appears in Chapter 7. Even so, Listing 10-11 presents a nice contrast to the approach in Listing 10-10, which had to be discarded.

Pass by reference

In the previous section or two, I take great pains to emphasize a certain point — that when a parameter has one of the eight primitive types, the parameter is passed by value. If you read this, you probably missed the emphasis on the parameter’s having one of the eight primitive types. The emphasis is needed because passing objects (reference types) doesn’t quite work the same way.

When you pass an object to a method, the object is passed by reference. What this means to you is that statements in the called method can change any values that are stored in the object’s variables. Those changes do affect the values that are seen by whatever code called the method. Listings 10-12 and 10-13 illustrate the point.

**Listing 10-12: What Is a City?**

```java
class City {
    int population;
}
```

**Listing 10-13: Passing an Object to a Method**

```java
class TrackPopulation3 {
    public static void main(String args[]) {
        City smackoverAR = new City();
        smackoverAR.population = 2232;
        birth(smackoverAR);
        System.out.println(smackoverAR.population);
    }

    static void birth(City aCity) {
        aCity.population++;
    }
}
```
When you run the code in Listings 10-12 and 10-13, the output that you get is the number 2,233. That’s good because the code has things like ++ and the word birth in it. The deal is, adding 1 to aCity.population inside the birth method actually changes the value of smackoverAR.population as it’s known in the main method.

To see how the birth method changes the value of smackoverAR.population, look at Figure 10-12. When you pass an object to a method, the computer doesn’t make a copy of the entire object. Instead, the computer makes a copy of a reference to that object. (Think of it the way it’s shown in Figure 10-12. The computer makes a copy of an arrow that points to the object.)

In Figure 10-12, you see just one instance of the City class, with a population variable inside it. Now keep your eye on that object as you read the following steps:

1. Just before the birth method is called, the smackoverAR variable refers to that object — the instance of the City class.

2. When the birth method is called, and smackoverAR is passed to the birth method’s aCity parameter, the computer copies the reference from smackoverAR to aCity. Now aCity refers to that same object — the instance of the City class.

3. When the statement aCity.population++ is executed inside the birth method, the computer adds 1 to the object’s population variable. Now the program’s one and only City instance has 2233 stored in its population variable.

4. The flow of execution goes back to the main method. The value of smackoverAR.population is printed. But smackoverAR refers to that one instance of the City class. So smackoverAR.population has the value 2233. The Kermongoos family is so proud.
Returning an object from a method

Believe it or not, there’s one nook and cranny of Java methods that the previous sections on parameter passing didn’t explore. When you call a method, the method can return something right back to the calling code. In previous chapters and sections, I return primitive values, such as `int` values, or nothing (otherwise known as `void`). In this section, I return a whole object. It’s an object of type `City` from Listing 10-12. The code that makes this happen is in Listing 10-14.

Listing 10-14: Here, Have a City

```java
class TrackPopulation4 {
    public static void main(String args[]) {
        City smackoverAR = new City();
        smackoverAR.population = 2232;
        smackoverAR = doBirth(smackoverAR);
        System.out.println(smackoverAR.population);
    }

    static City doBirth(City aCity) {
        City myCity = new City();
        myCity.population = aCity.population + 1;
        return myCity;
    }
}
```

If you run the code in Listing 10-14, you get the number 2,233. That’s good. The code works by telling the `doBirth` method to create another `City` instance. In the new instance, the value of `population` is 2333 (Figure 10-13).
When the `doBirth` method is finished being executed, that `City` instance is returned to the `main` method. Then, back in the `main` method, that instance (the one that `doBirth` returns) is assigned to the `smackoverAR` variable. (See Figure 10-14.) Now `smackoverAR` refers to a brand-new `City` instance — an instance whose population is 2,233.

In Listing 10-14, notice that the type consistency in the calling and returning of the `doBirth` method:

✔️ The `smackoverAR` variable has type `City`. The `smackoverAR` variable is passed to the `aCity` parameter, which is also of type `City`.

✔️ The `myCity` variable is of type `City`. The `myCity` variable is sent back in the `doBirth` method’s return statement. That’s consistent, because the `doBirth` method’s header begins with the promise `public static City` — the promise to return an object of type `City`.

✔️ The `doBirth` method returns an object of type `City`. Back in the `main` method, the object that the call to `doBirth` returns is assigned to the `smackoverAR` variable, and (you guessed it) the `smackoverAR` variable is of type `City`.

Aside from being very harmonious, all this type agreement is absolutely necessary. If you write a program, and your types don’t agree with one another in the program, the compiler spits out an unsympathetic `incompatible types` message.

**Epilogue**

Dora Kermongoos and her newborn baby daughter are safe, healthy, and resting happily in their Smackover, Arkansas, home.
Chapter 11

Using Arrays and Collections to Juggle Values

In This Chapter
- Dealing with several values at once
- Creating values as you get a program running
- Impressing other programmers with fancy generic types

Welcome to the Java Motel! No haughty bellhops, no overpriced room service, none of the usual silly puns. Just a clean double room at a darn good value.

Getting Your Ducks All in a Row

The Java Motel, with its ten comfortable rooms, sits in a quiet place off the main highway. Aside from a small, separate office, the motel is just one long row of ground floor rooms. Each room is easily accessible from the spacious front parking lot.

Oddly enough, the motel’s rooms are numbered 0 through 9. I could say that the numbering is a fluke — something to do with the builder’s original design plan. But the truth is that starting with 0 makes the examples in this chapter easier to write.

Anyway, you’re trying to keep track of the number of guests in each room. Because you have ten rooms, you may think about declaring ten variables:

```java
int guestsInRoomNum0, guestsInRoomNum1, guestsInRoomNum2,
guestsInRoomNum3, guestsInRoomNum4, guestsInRoomNum5,
guestsInRoomNum6, guestsInRoomNum7, guestsInRoomNum8,
guestsInRoomNum9;
```
Doing it this way may seem a bit inefficient. But inefficiency isn’t the only thing wrong with this code. Even more problematic is the fact that you can’t loop through these variables. To read a value for each variable, you have to copy the nextInt method ten times.

```java
    guestsInRoomNum0 = diskScanner.nextInt();
    guestsInRoomNum1 = diskScanner.nextInt();
    guestsInRoomNum2 = diskScanner.nextInt();
    ... and so on.
```

Surely a better way exists.

That better way involves an array. An array is a row of values, like the row of rooms in a one-floor motel. To picture the array, just picture the Java Motel:

- First, picture the rooms, lined up next to one another.
- Next, picture the same rooms with their front walls missing. Inside each room you can see a certain number of guests.
- If you can, forget that the two guests in Room 9 are putting piles of bills into a big briefcase. Ignore the fact that the guests in Room 6 haven’t moved away from the TV set in a day and a half. Instead of all these details, just see numbers. In each room, see a number representing the count of guests in that room. (If freeform visualization isn’t your strong point, look at Figure 11-1.)

![Figure 11-1: An abstract snapshot of rooms in the Java Motel.](image)

In the lingo of this chapter, the entire row of rooms is called an array. Each room in the array is called a component of the array (also known as an array element). Each component has two numbers associated with it:
The room number (a number from 0 to 9), which is called an index of the array

A number of guests, which is a value stored in a component of the array

Using an array saves you from all the repetitive nonsense in the sample code shown at the beginning of this section. For instance, to declare an array with ten values in it, you can write one fairly short statement:

```java
int guests[] = new int[10];
```

If you’re especially verbose, you can expand this statement so that it becomes two separate statements:

```java
int guests[];
guests = new int[10];
```

In either of these code snippets, notice the use of the number 10. This number tells the computer to make the guests array have ten components. Each component of the array has a name of its own. The starting component is named `guests[0]`, the next is named `guests[1]`, and so on. The last of the ten components is named `guests[9]`.

In creating an array, you always specify the number of components. The array’s indices start with 0 and end with the number that’s one less than the total number of components.

The snippets that I show you give you two ways to create an array. The first way uses one line. The second way uses two lines. If you take the single line route, you can put that line inside or outside a method. The choice is yours. On the other hand, if you use two separate lines, the second line, `guests = new int[10]`, should be inside a method.

In an array declaration, you can put the square brackets before or after the variable name. In other words, you can write `int guests[]` or `int[] guests`. The computer creates the same guests variable no matter which form you use.

**Creating an array in two easy steps**

Look once again at the two lines that you can use to create an array:

```java
int guests[];
guests = new int[10];
```
Each line serves its own distinct purpose:

- **`int guests[];`**: This first line is a declaration. The declaration reserves the array name (a name like `guests`) for use in the rest of the program. In the Java Motel metaphor, this line says, “I plan to build a motel here and put a certain number of guests in each room.” (See Figure 11-2.)

Never mind what the declaration `int guests[]` does. It’s more important to notice what the declaration `int guests[]` **doesn’t** do. The declaration doesn’t reserve ten memory locations. Indeed, a declaration like `int guests[]` doesn’t really create an array. All the declaration does is set up the `guests` variable. At that point in the code, the `guests` variable still doesn’t refer to a real array. (In other words, the motel hasn’t been built yet.)

- **`guests = new int[10];`**: This second line is an assignment statement. The assignment statement reserves space in the computer’s memory for ten `int` values. In terms of real estate, this line says, “I’ve finally built the motel. Go ahead and put guests in each room.” (Again, see Figure 11-2.)

![Figure 11-2: Two steps in creating an array.](image)

### Storing values

After you’ve created an array, you can put values into the array’s components. For instance, you would like to store the fact that Room 6 contains 4 guests. To put the value 4 in the component with index 6, you write `guests[6] = 4`.

Now business starts to pick up. A big bus pulls up to the motel. On the side of the bus is a sign that says “Noah’s Ark.” Out of the bus come 25 couples, each walking, stomping, flying, hopping, or slithering to the motel’s small office. Only 10 of the couples can stay at the Java Motel, but that’s okay because you can send the other 15 couples down the road to the old C-Side Resort and Motor Lodge.
Anyway, to register 10 couples into the Java Motel, you put a couple (2 guests) in each of your 10 rooms. Having created an array, you can take advantage of the array’s indexing and write a for loop, like this:

```java
for (int roomNum = 0; roomNum < 10; roomNum++) {
    guests[roomNum] = 2;
}
```

This loop takes the place of ten assignment statements. Notice how the loop’s counter goes from 0 to 9. Compare this with Figure 11-2, and remember that the indices of an array go from 0 to one less than the number of components in the array.

Now, given the way the world works, your guests won’t always arrive in neat pairs, and you’ll have to fill each room with a different number of guests. You probably store information about rooms and guests in a database. If you do, you can still loop through an array, gathering numbers of guests as you go. The code to perform such a task may look like this:

```java
resultset =
    statement.executeQuery("select GUESTS from RoomData");
for (int roomNum = 0; roomNum < 10; roomNum++) {
    resultset.next();
    guests[roomNum] = resultset.getInt("GUESTS");
}
```

But because this book doesn’t cover databases until Chapter 18 (on the CD-ROM), you may be better off reading numbers of guests from a plain text file. A sample file is shown in Figure 11-3. After you’ve made a file, you can call on the Scanner class to get values from the file. The code is shown in Listing 11-1, and the resulting output is in Figure 11-4.

For instructions on creating your own file like the one in Figure 11-3, see Chapter 8.

---

**Figure 11-3:**
The GuestList.txt file.

| GuestList.txt | 1 4 2 0 2 1 4 3 0 2 |
Listing 11-1: Filling an Array with Values

```java
import static java.lang.System.out;
import java.util.Scanner;
import java.io.File;
import java.io.IOException;

class ShowGuests {
    public static void main(String args[]) throws IOException {
        int guests[] = new int[10];
        Scanner diskScanner =
            new Scanner(new File("GuestList.txt"));

        for(int roomNum = 0; roomNum < 10; roomNum++) {
            guests[roomNum] = diskScanner.nextInt();
        }

        out.println("Room	Guests");
        for(int roomNum = 0; roomNum < 10; roomNum++) {
            out.print(roomNum);
            out.print("t");
            out.println(guests[roomNum]);
        }
    }
}
```

The code in Listing 11-1 has two for loops. The first loop reads numbers of guests, and the second loop writes numbers of guests.

Every array has a built-in length field. An array’s length is the number of components in the array. So, in Listing 11-1, if you print the value of guests.length, you get 10.
Tab stops and other special things

In Listing 11-1, some calls to print and println use the \t escape sequence. It’s called an escape sequence because you escape from displaying the letter t on the screen. Instead, the characters \t stand for a tab. The computer moves forward to the next tab stop before printing any more characters. Java has a few of these handy escape sequences. Some of them are shown in Table 11-1.

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>\b</td>
<td>backspace</td>
</tr>
<tr>
<td>\t</td>
<td>horizontal tab</td>
</tr>
<tr>
<td>\n</td>
<td>line feed</td>
</tr>
<tr>
<td>\f</td>
<td>form feed</td>
</tr>
<tr>
<td>\r</td>
<td>carriage return</td>
</tr>
<tr>
<td>&quot;</td>
<td>double quote “</td>
</tr>
<tr>
<td>‘</td>
<td>single quote ’</td>
</tr>
<tr>
<td>\</td>
<td>backslash \</td>
</tr>
</tbody>
</table>

Using an array initializer

Besides what you see in Listing 11-1, there’s another way to fill an array in Java. It’s with an array initializer. When you use an array initializer, you don’t even have to tell the computer how many components the array has. The computer figures this out for you.

Listing 11-2 shows a new version of the code to fill an array. The program’s output is the same as the output of Listing 11-1. (It’s the stuff shown in Figure 11-4.) The only difference between Listings 11-1 and 11-2 is the bold text in Listing 11-2. That bold doodad is an array initializer.
Listing 11-2: Using an Array Initializer

```java
import static java.lang.System.out;

class ShowGuests {
    public static void main(String args[]) {
        int guests[] = {1, 4, 2, 0, 2, 1, 4, 3, 0, 2};
        out.println("Room\tGuests");
        for (int roomNum = 0; roomNum < 10; roomNum++) {
            out.print(roomNum);
            out.print("\t");
            out.println(guests[roomNum]);
        }
    }
}
```

An array initializer can contain expressions as well as literals. In plain English, this means that you can put all kinds of things between the commas in the initializer. For instance, an initializer like `{1 + 3, myScanner.nextInt(), 2, 0, 2, 1, 4, 3, 0, 2}` works just fine.

### Stepping through an array with the enhanced for loop

With the new, improved, ultra-slick Java version 5.0 comes the enhanced for loop — the loop that doesn’t use counters or indices.

Listing 6-5 in Chapter 6 uses enhanced for loops to step through enum types. Loosely speaking, an enum type is just a bunch of values. But think about this chapter’s arrays. An array is a bunch of values, too. So it may come as no surprise that an enhanced for loop can step through an array’s values.

Listing 11-3 shows you how to do it.

Listing 11-3: Kids, Don’t Try This with Java 1.4!

```java
import static java.lang.System.out;

class ShowGuests {
    public static void main(String args[]) {
        int guests[] = {1, 4, 2, 0, 2, 1, 4, 3, 0, 2};
        int roomNum = 0;
```
out.println("Room\tGuests");
for (int numGuests : guests) {
    out.print(roomNum++);
    out.print("\t");
    out.println(numGuests);
}

Listings 11-1 and 11-3 have the same output. It’s in Figure 11-4.

If you look at the loop in Listing 11-3, you see the same old pattern. Just like the loops in Listing 6-5, this example’s loop has three parts:

\[ \text{for (variable-type variable-name : range-of-values)} \]

The first two parts are variable-type and variable-name. The loop in Listing 11-3 defines a variable named numGuests, and numGuests has type int. During each loop iteration, the variable numGuests takes on a new value. Look at Figure 11-4 to see these values. The initial value is 1. The next value is 4. After that comes 2. And so on.

Where is the loop finding all these numbers? The answer lies in the loop’s range-of-values. In Listing 11-3, the loop’s range-of-values is guests. So, during the initial loop iteration, the value of numGuests is guests[0] (which is 1). During the next iteration, the value of numGuests is guests[1] (which is 4). After that comes guests[2] (which is 2). And so on.

**Searching**

You’re sitting behind the desk at the Java Motel. Look! Here comes a party of five. These people want a room, so you need software that checks to see whether a room is vacant. If one is, the software needs to modify the GuestList.txt file (refer to Figure 11-3) by replacing the number 0 with the number 5. As luck would have it, the software is right on your hard drive. The software is shown in Listing 11-4.

**Listing 11-4: Do You Have a Room?**

```java
import static java.lang.System.out;
import java.util.Scanner;
import java.io.File;
import java.io.IOException;
import java.io.PrintStream;
```
Listing 11-4 (continued)

public class FindVacancy {

    public static void main(String args[]) throws IOException {
        Scanner kbdScanner = new Scanner(System.in);
        Scanner diskScanner = new Scanner(new File("GuestList.txt"));
        int guests[] = new int[10];
        int roomNum;

        for (roomNum = 0; roomNum < 10; roomNum++) {
            guests[roomNum] = diskScanner.nextInt();
        }

        roomNum = 0;
        while (roomNum < 10 && guests[roomNum] != 0) {
            roomNum++;
        }

        if (roomNum == 10) {
            out.println("Sorry, no vacancy");
        } else {
            out.print("How many people for room ");
            out.print(roomNum);
            out.print("? ");
            guests[roomNum] = kbdScanner.nextInt();

            PrintStream listOut =
                    new PrintStream("GuestList.txt");

            for (roomNum = 0; roomNum < 10; roomNum++) {
                listOut.print(guests[roomNum]);
                listOut.print(" ");
            }
        }
    }
}

Figures 11-5 through 11-7 show the running of the code in Listing 11-4. Back in Figure 11-3, the motel starts with two vacant rooms — Rooms 3 and 8. (Remember, the rooms start with Room 0.) The first time that you run the code in Listing 11-4, the program tells you that Room 3 is vacant and puts five people into the room. The second time you run the code, the program finds the remaining vacant room (Room 8) and puts a party of ten in the room. (What a party!) The third time you run the code, you don’t have any more vacant rooms. When the program discovers this, it displays the message Sorry, no vacancy, omitting at least one letter in the tradition of all motel neon signs.
Each run of Listing 11-4’s code writes a brand-new `GuestList.txt` file. If you use JCreator, you can easily monitor the changes to `GuestList.txt`. Keep `GuestList.txt` showing in JCreator’s Editor pane. After running the code in Listing 11-4, switch to some other window on your screen (your Web browser, for instance) or to some other document in JCreator’s Editor pane. Then return to the display of `GuestList.txt` in JCreator. Upon your return, JCreator tells you that `GuestList.txt` has been modified. “Do you want to reload it?” asks JCreator. “Yes,” you click. Then JCreator displays the updated version of `GuestList.txt`.

The code in Listing 11-4 uses tricks from other chapters and sections of this book. The code’s only brand-new feature is the use of `PrintStream` to write to a disk file. Think about any example in this book that calls `System.out.println`, or their variants. What’s really going on when you call one of these methods?

The thing called `System.out` is an object. The object is defined in the Java API. In fact, `System.out` is an instance of a class named `java.io.PrintStream` (or just `PrintStream` to its close friends). Now each object created from the
PrintStream class has methods named print and println. Just as each Account object in Listing 7-3 has a display method, and just as the DecimalFormat object in Listing 10-1 has a format method, so the PrintStream object named out has print and println methods. When you call System.out.println, you’re calling a method that belongs to a PrintStream instance.

Okay, so what of it? Well, System.out always stands for some text area on your computer screen. If you create your own PrintStream object, and you make that object refer to a disk file, then that PrintStream object refers to the disk file. When you call that object’s print method, you write text to a file on your hard drive.

So in Listing 11-4, when you say

```java
PrintStream listOut =
    new PrintStream("GuestList.txt");
listOut.print(guests[roomNum]);
listOut.print(" ");
```

you’re telling Java to write text to a file on your hard drive — the GuestList.txt file.

That’s how you update the count of guests staying in the hotel. When you call listOut.print for the number of guests in Room 3, you may print the number 5. So, between Figures 11-5 and 11-6, a number in the GuestList.txt file changes from 0 to 5. Then in Figure 11-6, you run the program a second time. When the program gets data from the newly written GuestList.txt file, Room 3 is no longer vacant. So this time, the program suggests Room 8.

Like many other methods and constructors of its kind, the PrintStream constructor doesn’t pussyfoot around with files. If it can’t find a GuestList.txt file, the constructor creates one and prepares to write values into it. But, if a GuestList.txt file already exists, the constructor clobbers the existing file and prepares to write to a new, empty GuestList.txt file. If you don’t like it when files are clobbered, take precautions before calling the PrintStream constructor.

This is more an observation than a tip. Say that you want to read data from a file named Employees.txt. To do this, you make a scanner. You call new Scanner(new File("Employees.txt")). If you accidentally call new Scanner("Employees.txt") without the new File part, the call doesn’t connect to your Employees.txt file. But notice how you prepare to write data to a file. You make a PrintStream instance by calling new PrintStream("GuestList.txt"). You don’t use new File anywhere in the call. If you goof and accidentally include new File, the Java compiler becomes angry, jumps out, and bites you.
In Listing 11-4, the condition `roomNum < 10 && guests[roomNum] != 0` can be really tricky. If you move things around, and write `guests[roomNum] != 0 && roomNum < 10`, you can get yourself into lots of trouble. For details, see this book’s Web site.

**Arrays of Objects**

The Java Motel is open for business, now with improved guest registration software! The people who brought you this chapter’s first section are always scratching their heads, looking for the best ways to improve their services. Now, with some ideas from object-oriented programming, they’ve started thinking in terms of a `Room` class.

“And what,” you ask, “is a `Room` instance?” That’s easy. A `Room` instance has three properties — the number of guests in the room, the room rate, and a smoking/nonsmoking stamp. Figure 11-8 illustrates the situation.

Listing 11-5 shows the code that describes the `Room` class. As promised, each instance of the `Room` class has three variables: the guests, rate, and smoking variables. (A `false` value for the boolean variable, `smoking`, indicates a non-smoking room.) In addition, the entire `Room` class has a `static` variable named `currency`. This currency object makes room rates look like dollar amounts.

To find out what static means, see Chapter 10.

**Listing 11-5: So This is What a Room Looks Like!**

```java
import static java.lang.System.out;
import java.util.Scanner;
import java.text.NumberFormat;
```

(continued)
Listing 11-5 (continued)

class Room {
    private int guests;
    private double rate;
    private boolean smoking;
    private static NumberFormat currency =
        NumberFormat.getCurrencyInstance();

    public void readRoom(Scanner diskScanner) {
        guests = diskScanner.nextInt();
        rate = diskScanner.nextDouble();
        smoking = diskScanner.nextBoolean();
    }

    public void writeRoom() {
        out.print(guests);
        out.print("\t");
        out.print(currency.format(rate));
        out.print("\t");
        out.println(smoking ? "yes" : "no");
    }
}

Listing 11-5 has a few interesting quirks, but I'd rather not describe them until after you see all the code in action. That's why, at this point, I move right on to the code that calls the Listing 11-5 code. After you read about arrays of rooms (shown in Listing 11-6), check out my description of the Listing 11-5 quirks.

Using the Room class

So now you need an array of rooms. The code to create such a thing is in Listing 11-6. The code reads data from the RoomList.txt file. (Figure 11-9 shows the contents of the RoomList.txt file.)

Figure 11-10 shows a run of the code in Listing 11-6.

Listing 11-6: Would You Like to See a Room?

import java.io.File;
import java.io.IOException;
import java.lang.System.out;
import java.util.Scanner;
import java.util.List;

class Room {
    private int guests;
    private double rate;
    private boolean smoking;
    private static NumberFormat currency =
        NumberFormat.getCurrencyInstance();

    public void readRoom(Scanner diskScanner) {
        guests = diskScanner.nextInt();
        rate = diskScanner.nextDouble();
        smoking = diskScanner.nextBoolean();
    }

    public void writeRoom() {
        out.print(guests);
        out.print("\t");
        out.print(currency.format(rate));
        out.print("\t");
        out.println(smoking ? "yes" : "no");
    }
}

Listing 11-5 has a few interesting quirks, but I'd rather not describe them until after you see all the code in action. That's why, at this point, I move right on to the code that calls the Listing 11-5 code. After you read about arrays of rooms (shown in Listing 11-6), check out my description of the Listing 11-5 quirks.

Using the Room class

So now you need an array of rooms. The code to create such a thing is in Listing 11-6. The code reads data from the RoomList.txt file. (Figure 11-9 shows the contents of the RoomList.txt file.)

Figure 11-10 shows a run of the code in Listing 11-6.
public static void main(String args[]) throws IOException {
    Room rooms[];
    rooms = new Room[10];
    Scanner diskScanner =
        new Scanner(new File("RoomList.txt"));
    for (int roomNum = 0; roomNum < 10; roomNum++) {
        rooms[roomNum] = new Room();
        rooms[roomNum].readRoom(diskScanner);
    }
    out.println("Room\tGuests\tRate\tSmoking?\n");
    for (int roomNum = 0; roomNum < 10; roomNum++) {
        out.print(roomNum);
        out.print("\t");
        rooms[roomNum].writeRoom();
    }
}

RoomList.txt

</tbody>
</table>

Figure 11-9:
A file of Room data.
Say what you want about the code in Listing 11-6. As far as I'm concerned, only one issue in the whole listing should concern you. And what, you ask, is that issue? Well, to create an array of objects, you have to do three things: make the array variable, make the array itself, and then construct each individual object in the array. This is different from creating an array of `int` values or an array containing any other primitive type values. When you create an array of primitive type values, you do only the first two of these three things.

To help make sense of all this, follow along in Listing 11-6 and Figure 11-11 as you read the following points.

---

**General Output**

---

<table>
<thead>
<tr>
<th>Room</th>
<th>Guests</th>
<th>Rate</th>
<th>Smoking?</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>$80.00</td>

</table>

---

Figure 11-10:
A run of the code in Listing 11-6.

---

Figure 11-11:
Steps in creating an array of objects.
Room rooms[]: This declaration creates a rooms variable. This variable is destined to refer to an array (but doesn’t yet refer to anything at all).

rooms = new Room[10]: This statement reserves ten slots of storage in the computer’s memory. The statement also makes the rooms variable refer to the group of storage slots. Each slot is destined to refer to an object (but doesn’t yet refer to anything at all).

rooms[roomNum] = new Room(): This statement is inside a for loop. The statement is executed once for each of the ten room numbers. For example, the first time through the loop, this statement says rooms[0] = new Room(). That first time around, the statement makes the slot rooms[0] refer to an actual object (an instance of the Room class).

Although it’s technically not considered a step in array making, you still have to fill each object’s variables with values. For instance, the first time through the loop, the readRoom call says rooms[1].readRoom(diskScanner), which means, “Read data from the RoomList.txt file into the rooms[1] object’s variables.” Each time through the loop, the program creates a new object and reads data into that new object’s variables.

Similar to creating arrays of primitive values, you can squeeze the steps together. For instance, you can do the first two steps in one fell swoop, like this:

```
Room rooms[] = new Room[10];
```

You can also use an array initializer. (For an introduction to array initializers, see the section, “Using an array initializer,” earlier in this chapter.)

**Yet another way to beautify your numbers**

You can make numbers look nice in plenty of ways. For instance, Listing 7-7 uses printf and Listing 10-1 uses a DecimalFormat. But in Listing 11-5, I display a currency amount. I use the NumberFormat class with its getCurrencyInstance method.

If you compare the formatting statements in Listings 10-1 and 11-5, you don’t see much difference.

One listing uses a constructor; the other listing calls getCurrencyInstance.

The getCurrencyInstance method is a good example of what’s called a factory method. A factory method is a convenient tool for creating commonly used objects. People always need code that displays dollar
amounts. So the `getCurrencyInstance` method creates a dollar format without forcing you to write `new DecimalFormat("$###0.00;($###0.00)")`.

Like a constructor, a factory method returns a brand-new object. But unlike a constructor, a factory method has no special status. When you create a factory method, you can name it anything you want. When you call a factory method, you don’t use the keyword `new`.

> **One listing uses** `DecimalFormat`; the **other listing uses** `NumberFormat`.

A decimal number is a certain kind of number. (In fact, a decimal number is a number written in the base-10 system.) Accordingly, the `DecimalFormat` class is a subclass of the `NumberFormat` class. The `DecimalFormat` methods are more specific, so for most purposes, I use `DecimalFormat`. But it’s harder to use the `DecimalFormat` class’s `getCurrencyInstance` method. So for programs that involve money, I tend to use `NumberFormat`.

> **Both listings use** `format` **methods**.

In the end, you just write something like `currency.format(rate)` or `decFormat.format(average)`. After that, Java does the work for you.

## The conditional operator

Listing 11-5 uses an interesting doodad called the **conditional operator**. This conditional operator takes three expressions, and returns the value of just one of them. It’s like a mini `if` statement. When you use the conditional operator, it looks something like this:

```
conditionToBeTested ? expression1 : expression2
```

The computer evaluates the `conditionToBeTested` condition. If the condition is true, the computer returns the value of `expression1`. But, if the condition is false, the computer returns the value of `expression2`.

So, in the code

```
smoking ? "yes" : "no"
```

the computer checks to see whether `smoking` has the value `true`. If so, the whole three-part expression stands for the first string, "yes". If not, the whole expression stands for the second string, "no".

In Listing 11-5, one of the strings, "yes" or "no", gets displayed by the call to `out.println`. Which string gets displayed depends on whether `smoking` has the value `true` or `false`. 
Command Line Arguments

Since you first started working with Java, you’ve been seeing this `String args[]` business in the header of every `main` method. Well, it’s high time you found out what that business is all about.

When you want to run a Java program, you can get the program going by choosing Build ➪ Execute Project or by clicking somewhere else within your particular development environment.

In plenty of situations, clicking is all you need to do. But sometimes, you want to add a little extra information as you get the program going. Say, for instance, that the program puts a new file on your computer’s hard drive. Maybe, when you start the program, you want to tell the program what it should name that new file. Hey, maybe you give the program even more information. Imagine that this file of yours has random numbers in it. (It’s a list of numbers to be read aloud at your motel’s weekly Bingo game.) When you get the program running, you tell the program the name of the new file and how many numbers you want the new file to contain.

All this leads to one big question. How do you give the program some extra information each time the program starts running?

That’s where this `String args[]` business enters the picture. The parameter `args[]` is an array of `String` values. These `String` values are called command line arguments.

Using command line arguments in a Java program

Listing 11-7 shows you how to use command line arguments in your code.

Listing 11-7: Generate a File of Numbers

```java
import java.util.Random;
import java.io.File;
import java.io.PrintStream;
import java.io.IOException;
```

(continued)
Listing 11-7 (continued)

class MakeRandomNumsFile {
    public static void main(String args[]) throws IOException {
        Random generator = new Random();

        if (args.length < 2) {
            System.out.println("Usage: MakeRandomNumsFile filename number");
            System.exit(1);
        }

        PrintStream printOut = new PrintStream(args[0]);
        int numLines = Integer.parseInt(args[1]);

        for (int count = 1; count <= numLines; count++) {
            printOut.println(generator.nextInt(10) + 1);
        }
    }
}

In preparing the code for this book’s CD-ROM, I tweaked some settings for this section’s JCreator project. As a result, choosing Build ➤ Execute Project gets you the window shown in Figure 11-12. Before executing the code, JCreator prompts the user for extra information. In Figure 11-12, I type two extra pieces of information — the MyNumberedFile.txt file and the value 5. After clicking OK, the code in Listing 11-7 begins running.

![Figure 11-12: JCreator prompts the user for command line arguments.](image)

When the code begins running, the args array gets its values. In the main method of Listing 11-7, the array component args[0] automatically takes on the value "MyNumberedFile.txt", and args[1] automatically becomes "5". So the program’s assignment statements end up having the following meaning:

```java
PrintStream printOut = new PrintStream("MyNumberedFile.txt");
int numLines = Integer.parseInt("5");
```
The program creates a file named *MyNumberedFile.txt* and sets `numLines` to 5. So later in the code, the program randomly generates five values and puts those values into *MyNumberedFile.txt*. One run of the program gave me the file shown in Figure 11-13.

![Figure 11-13: A file from a run of the code in Listing 11-7.](image)

Notice how each command line argument is a `String` value. When you look at `args[1]`, you don’t see the number 5 — you see the string ”5” with a digit character in it. Unfortunately, you can’t use that ”5” to do any counting. To get an `int` value from ”5”, you have to apply the `parseInt` method.

The `parseInt` method lives inside a class named `Integer`. So, to call `parseInt`, you preface the name `parseInt` with the word `Integer`. The `Integer` class has all kinds of handy methods for doing things with `int` values.

In Java, `Integer` is the name of a class, and `int` is the name of a primitive (simple) type. The two things are related, but they’re not the same. The `Integer` class has methods and other tools for dealing with `int` values.

### Checking for the right number of command line arguments

What happens if the user makes a mistake? What if the dialog box in Figure 11-12 (shown previously) pops up and the user forgets to type the number 5. The user types *MyNumberedFile.txt*, and nothing else.

Then the computer assigns ”MyNumberedFile.txt” to `args[0]`, but it doesn’t assign anything to `args[1]`. This is bad. If the computer ever reaches the statement

```java
int numLines = Integer.parseInt(args[1]);
```

then the program crashes with an unfriendly `ArrayIndexOutOfBoundsException` Exception.
So, what do you do about this? In Listing 11-7, you check the length of the `args` array. You compare `args.length` with 2. If the `args` array has fewer than two components, you display a message on the screen and you exit from the program. Figure 11-14 shows the resulting output.

Despite the checking of `args.length` in Listing 11-7, the code still isn’t crashproof. If you type `five` instead of `5`, the program takes a nosedive with a `NumberFormatException`. The second command line argument can’t be a word. The argument has to be a number (and a whole number at that). I can add statements to Listing 11-7 to make the code more bulletproof, but checking for the `NumberFormatException` is better done in Chapter 12.

When you’re working with command line arguments, you can enter a `String` value with a blank space in it. Just enclose the value in double quote marks. For instance, you can run the code of Listing 11-7 with arguments `"My File.txt" 7`.

### Setting up JCreator for command line arguments

Normally, when you choose Build ➪ Execute Project, the computer starts running your code. The computer doesn’t wait for you to enter any extra pieces of information, so things like an extra filename and the number of values in the file can get lost in the dust. To use command line arguments, the computer has to pause for a moment. During this pause, the computer prompts the user to type in a few more bits of information.

For the code on the CD-ROM, I rigged JCreator to display the dialog box in Figure 11-12. But if you’re creating a program on your own, how do you tell JCreator to pause and prompt the user for information? To find out, follow these steps:
1. In JCreator's File View pane, find the project whose main program uses command line arguments.

   If you're using this book's sample code, pick the Listing1107 project.

2. Right-click the project's branch in the File View tree. In the resulting context menu, choose Sets as Active Project.

   This makes the appropriate project active.

   It's easy to forget Step 2. Don't forget Step 2!

3. Again, right-click the project's branch in the File View tree. In the resulting context menu, choose Properties.

   A Project Properties window appears.

4. In the Project Properties window, select the JDK Tools tab. (See Figure 11-15.)

   ![Figure 11-15: Preparing to copy the default Run Application configuration.](image)

5. Make sure that Run Application appears in the Select Tool Type dropdown list.

6. Beneath the Select Tool Type list, select the Default configuration.

7. Click the Copy button.

   A window titled Tool Configuration : Run Application appears.

8. In the Tool Configuration window’s Name text box, type anything that reminds you what this example is all about.

   In Figure 11-16, I typed `GetCommandLineArguments`.

   ![Figure 11-16: Copying the default Run Application configuration.](image)
9. In the Tool Configuration window, select the Parameters tab.

10. Select the Prompt for main Method Arguments check box.

11. Click OK.

    The Tool Configuration window disappears. Now you're staring at the Project Properties window again.

12. In the Project Properties window, select the check box next to your newly created configuration.

    In Figure 11-17, I selected my new GetCommandLineArguments configuration.

13. Click OK.

    Isn't that the way these lists of instructions always seem to end?
After following Steps 1 through 13, your project is changed. Whenever that project is the active project, choosing Build ➪ Execute Project gives you a dialog box like the one shown previously in Figure 11-12.

For hints on the use of command line arguments in environments other than JCreator, see this book’s Web site.

The sun is about to set on this book’s discussion of arrays. The next section deals with something slightly different. But before you leave the subject of arrays, think about this: An array is a row of things, and not every kind of thing fits into just one row. Take the motel in this chapter’s first few examples. The motel rooms, numbered 0 through 9, are in one big line. But what if you move up in the world? You buy a big hotel with 50 floors and with 100 rooms on each floor. Then the data is square shaped. We have 50 rows, and each row contains 100 items. Sure, you can think of the rooms as if they’re all in one big row, but why should you have to do that? How about having a two-dimensional array? It’s a square-shaped array in which each component has two indices — a row number and a column number. Alas, I have no space in this book to show you a two-dimensional array (and I can’t afford a big hotel’s prices anyway). But if you visit this book’s Web site, you can read all about it.

Using Java Collections

Arrays are nice, but arrays have some serious limitations. Imagine that you store customer names in some predetermined order. Your code contains an array, and the array has space for 100 names.

```java
String name[] = new String[100];
for (int i = 0; i < 100; i++) {
    name[i] = new String();
}
```

All is well until, one day, customer number 101 shows up. As your program runs, you enter data for customer 101, hoping desperately that the array with 100 components can expand to fit your growing needs.

No such luck. Arrays don’t expand. Your program crashes with an `ArrayIndexOutOfBoundsException`.

“In my next life, I’ll create arrays of length 1,000,” you say to yourself. And when your next life rolls around, you do just that.
String name[] = new String[1000];
for (int i = 0; i < 1000; i++) {
    name[i] = new String();
}

But during your next life, an economic recession occurs. Instead of having 101 customers, you have only 3 customers. Now you’re wasting space for 1,000 names when space for 3 names would do.

And what if no economic recession occurs? You’re sailing along with your array of size 1,000, using a tidy 825 spaces in the array. The components with indices 0 through 824 are being used, and the components with indices 825 through 999 are waiting quietly to be filled.

One day, a brand-new customer shows up. Because your customers are stored in order (alphabetically by last name, numerically by Social Security number, whatever), you want to squeeze this customer into the correct component of your array. The trouble is that this customer belongs very early on in the array, at the component with index 7. What happens then?

You take the name in component number 824 and move it to component 825. Then you take the name in component 823 and move it to component 824. Take the name in component 822 and move it to component 823. You keep doing this until you’ve moved the name in component 7. Then you put the new customer’s name into component 7. What a pain! Sure, the computer doesn’t complain. (If the computer has feelings, it probably likes this kind of busy work.) But as you move around all these names, you waste processing time, you waste power, and you waste all kinds of resources.

“In my next life, I’ll leave three empty components between every two names.” And of course, your business expands. Eventually you find that three isn’t enough.

Collection classes to the rescue

The issues in the previous few paragraphs aren’t new. Computer scientists have been working on these issues for a long time. They haven’t discovered any magic one-size-fits-all solution, but they’ve discovered some clever tricks.

The Java API has a bunch of classes known as collection classes. Each collection class has methods for storing bunches of values. And each collection class’s methods use some clever tricks. For you, the bottom line is as follows: Certain collection classes deal as efficiently as possible with the issues raised in the previous few paragraphs. If you’re writing code, and you know that you
have to deal with such issues, you can use these collection classes and call the classes’ methods. Instead of fretting about a customer whose name belongs in position 7, you can just call a class’s `add` method. The method inserts the name at a position of your choice, and deals reasonably with whatever ripple effects have to take place. In the best circumstances, the insertion is very efficient. In the worst circumstances, you can rest assured that the code does everything the best way it can.

**Using an ArrayList**

The most useful of Java’s collection classes is the `ArrayList`. Listing 11-8 shows you how it works.

**Listing 11-8: Working with a Java Collection**

```java
import static java.lang.System.out;
import java.util.Scanner;
import java.io.File;
import java.io.IOException;
import java.util.ArrayList;

class ShowNames {
    public static void main(String args[])
        throws IOException {
        ArrayList<String> people = new ArrayList<String>();
        Scanner diskScanner =
            new Scanner(new File("names.txt"));

        while (diskScanner.hasNext()) {
            people.add(diskScanner.nextLine());
        }

        people.remove(0);
        people.add(2, "Jim Newton");

        for (String name : people) {
            out.println(name);
        }
    }
}
```

Figure 11-18 shows you a sample `names.txt` file. The code in Listing 11-8 reads that `names.txt` file, and prints the stuff in Figure 11-19.
All the interesting things happen when you execute the remove and add methods. The variable named people refers to an ArrayList object. When you call that object’s remove method

```
people.remove(0);
```

you eliminate a value from the list. In this case, you eliminate whatever value is in the list’s initial position (the position numbered 0). So in Listing 11-8, the call to remove takes the name Barry Burd out of the list.

That leaves only eight names in the list, but then the next statement,

```
people.add(2, "Jim Newton");
```

inserts a name into position number 2. (After Barry is removed, position number 2 is the position occupied by Harry Spoonswagler, so Harry moves to position 3, and Jim Newton becomes the number 2 man.)

Notice that an ArrayList object has two different add methods. The method that adds Jim Newton has two parameters — a position number and a value to be added. Another add method

```
people.add(diskScanner.nextLine());
```

takes only one parameter. This statement takes whatever name it finds on a line of the input file and appends that name to the end of the list. (The add method with only one parameter always appends its value to what’s currently the end of the ArrayList object.)
Using generics (hot stuff!)

Look again at Listing 11-8, and notice the funky `ArrayList` declaration:

```java
ArrayList<String> people = new ArrayList<String>();
```

In Java 5.0, each collection class is *generified*. That ugly-sounding word means that every declaration should contain `<SomeTypeName>`. The thing that's sandwiched between `<` and `>` tells Java what kinds of values the new collection may contain.

For example, in Listing 11-8 the words `ArrayList<String> people` say that the `people` variable can refer only to a collection of `String` values. So from that point on, any reference to an item from the `people` collection is treated exclusively as a `String`. If you write

```java
people.add(new Room());
```

then the compiler coughs up your code and spits it out because a `Room` isn’t the same as a `String`. (This coughing and spitting happens even if the compiler has access to the `Room` class’s code — the code in Listing 11-5.) But the statement

```java
people.add("George Gow");
```

is just fine. Because "George Gow" has type `String`, the compiler smiles happily.

Testing for the presence of more data

Here’s a pleasant surprise. When you write a program like the one shown previously in Listing 11-8, you don’t have to know how many names are in the input file. Having to know the number of names may defeat the purpose of using the easily expandable `ArrayList` class. Instead of looping until you read exactly nine names, you can loop until you run out of data.

The `Scanner` class has several nice methods like `hasNextInt`, `hasNextDouble`, and plain old `hasNext`. Each of these methods checks for more input data. If there’s more data, the method returns `true`. Otherwise, the method returns `false`.

Listing 11-8 uses the general purpose `hasNext` method. This `hasNext` method returns `true` as long as there’s anything more to read from the program’s input. So after the program scoops up that last Hugh R. DaReader line in Figure 11-18, the subsequent `hasNext` call returns `false`. This `false` condition ends execution of the `while` loop and plummets the computer toward the remainder of the Listing 11-8 code.
All about generics

One of Java's original design goals was to keep the language as simple as possible. The language's developer took some unnecessarily complicated features of C++ and tossed them out the window. The result was a language that was elegant and sleek. Some people said the language was too sleek. So after several years of discussion and squabbling, Java is becoming a bit more complicated.

In particular, Java 5.0 includes enum types, enhanced for loops, static import, and some other interesting features. But the most talked-about new feature is the introduction of generics.

```java
ArrayList<String> people = new ArrayList<String>();
```

The use of anything like `<String>` is new in Java 5.0. In old-style Java, you'd write

```java
ArrayList people = new ArrayList();
```

In those days, an ArrayList could store almost anything you wanted to put in it — a number, an Account, a Room, a String — anything. The ArrayList class was very versatile, but with this versatility came some headaches. If you could put anything into an ArrayList, you couldn't easily predict what you would get out of an ArrayList. In particular, you couldn't easily write code that assumed you had stored certain types of values in the ArrayList. Here's an example:

```java
ArrayList things =
    new ArrayList();
things.add(new Account());
Account myAccount =
    things.get(0);
//DON'T USE THIS. IT'S BAD CODE.
```

In the third line, the call to `get(0)` grabs the earliest value in the things collection. The call to `get(0)` is okay, but then the compiler chokes on the attempted assignment to `myAccount`. You get a message on the third line saying that whatever you get from the things list can't be stuffed into the `myAccount` variable. You get this message because, by the time the compiler reaches the third line, it has forgotten that the item added on the second line was of type `Account`!

The introduction of generics fixes this problem:

```java
ArrayList<Account> things =
    new ArrayList<Account>();
things.add(new Account());
Account myAccount =
    things.get(0);
//USE THIS CODE INSTEAD. IT'S GOOD CODE.
```

Adding `<Account>` in two places tells the compiler that `things` stores Account instances — nothing else. So, in the third line above, you get a value from the `things` collection. Then, because `things` stores only Account objects, you can make `myAccount` refer to that new value. It works!
Chapter 12
Looking Good When Things Take Unexpected Turns

In This Chapter
► Recovering from bad input and other nasty situations
► Making your code (more or less) crash proof
► Defining your own exception class

September 9, 1945: A moth flies into one of the relays of the Harvard Mark II computer and gums up the works. This becomes the first recorded case of a real computer bug.

April 19, 1957: Herbert Bright, manager of the data processing center at Westinghouse in Pittsburgh, receives an unmarked deck of computer punch cards in the mail (which is like getting an unlabeled CD-ROM in the mail today). Mr. Bright guesses that this deck comes from the development team for FORTRAN — the first computer programming language. He’s been waiting a few years for this software. (No Web downloads were available at the time.) Armed with nothing but this good guess, Bright writes a small FORTRAN program and tries to compile it on his IBM 704. (The IBM 704 lives in its own specially built, 2,000-square-foot room. With vacuum tubes instead of transistors, the machine has a whopping 32K of RAM. The operating system has to be loaded from tape before the running of each program, and a typical program takes between two and four hours to run.) After the usual waiting time, Bright’s attempt to compile a FORTRAN program comes back with a single error — a missing comma in one of the statements. Bright corrects the error, and the program runs like a charm.

July 22, 1962: Mariner I, the first U.S. spacecraft aimed at another planet, is destroyed when it behaves badly four minutes after launch. The bad behavior is attributed to a missing bar (like a hyphen) in the formula for the rocket’s velocity.
Around the same time, orbit computation software at NASA is found to contain the incorrect statement `DO 10 I=1.10` (instead of the correct `DO 10 I=1,10`). In modern notation, this is like writing `do10i = 1.10` in place of `for (int i=1; i<=10; i++)`. The change from a comma to a period turns a loop into an assignment statement.

Any historically accurate facts in these notes were borrowed from the following sources: the Computer Folklore newsgroup (`alt.folklore.computers`, which you can access through `groups.google.com`), the Free On-line Dictionary of Computing (`www.foldoc.org`), the “Looking Back” column in *Computer* magazine (`www.computer.org/computer`), and the Web pages of the IEEE (`www.computer.org/history`).

## Handling Exceptions

You’re taking inventory. This means counting item after item, box after box, and marking the numbers of such things on log sheets, in little handheld gizmos, and into forms on computer keyboards. A particular part of the project involves entering the number of boxes that you find on the Big Dusty Boxes That Haven’t Been Opened Since Year One shelf. Rather than break the company’s decades-old habit, you decide not to open any of these boxes. You arbitrarily assign the value $3.25 to each box.

Listing 12-1 shows the software to handle this bit of inventory. The software has a flaw, which is revealed in Figure 12-1. When the user enters a whole number value, things are okay. But when the user enters something else (like the number 3.5), the program comes crashing to the ground. Surely something can be done about this. Computers are stupid, but they’re not so stupid that they should fail royally when a user enters an improper value.

### Listing 12-1: Counting Boxes

```java
import static java.lang.System.out;
import java.util.Scanner;
import java.text.NumberFormat;

class InventoryA {
    public static void main(String args[]) {
        final double boxPrice = 3.25;
        Scanner myScanner = new Scanner(System.in);
        NumberFormat currency = NumberFormat.getCurrencyInstance();
    }
}
```
out.print("How many boxes do we have? ");
String numBoxesIn = myScanner.next();
int numBoxes = Integer.parseInt(numBoxesIn);
out.print("The value is ");
out.println(currency.format(numBoxes * boxPrice));
}
}

The key to fixing a program bug is examining the message that appears when the program crashes. The inventory program's message says java.lang.NumberFormatException. That means a class named NumberFormatException is in the java.lang API package. Somehow, the call to Integer.parseInt brought this NumberFormatException class out of hiding.

For a brief explanation of the Integer.parseInt method, see Chapter 11.

Well, here's what's going on. The Java programming language has a mechanism called exception handling. With exception handling, a program can detect that things are about to go wrong and respond by creating a brand-new object. In the official terminology, the program is said to be throwing an exception. That new object, an instance of the Exception class, is passed like a hot potato from one piece of code to another until some piece of code decides to catch the exception. When the exception is caught, the program executes some recovery code, buries the exception, and moves on to the next normal statement as if nothing had ever happened. The process is illustrated in Figure 12-2.

The whole thing is done with the aid of several Java keywords. These keywords are as follows:

- throw: Creates a new exception object.
- throws: Passes the buck from a method up to whatever code called the method.
try: Encloses code that has the potential to create a new exception object. In the usual scenario, the code inside a try clause contains calls to methods whose code can create one or more exceptions.

catch: Deals with the exception, buries it, and then moves on.

So, the truth is out. Through some chain of events like the one shown in Figure 12-2, the method Integer.parseInt can throw a NumberFormatException. When you call Integer.parseInt, this NumberFormatException is passed on to you.

The Java API (Application Programming Interface) documentation for the parseInt method says, “Throws: NumberFormatException — if the string does not contain a parsable integer.” Once in a while, reading the documentation actually pays.

If you call yourself a hero, you’d better catch the exception so that all the other code can get on with its regular business. Listing 12-2 shows the catching of an exception.

```java
void method1() {
    try {  
        method2();
    } catch (Exception e) {
    }
}

void method2() throws Exception {
    method3();
}

void method3() throws Exception {
    method4();
}

void method4() throws Exception {
    throw new Exception();
}
```

Figure 12-2: Throwing, passing, and catching an exception.
import static java.lang.System.out;
import java.util.Scanner;
import java.text.NumberFormat;

class InventoryB {
    public static void main(String args[]) {
        final double boxPrice = 3.25;
        Scanner myScanner = new Scanner(System.in);
        NumberFormat currency = NumberFormat.getCurrencyInstance();

        out.print("How many boxes do we have? ");
        String numBoxesIn = myScanner.next();

        try {
            int numBoxes = Integer.parseInt(numBoxesIn);
            out.print("The value is ");
            out.println(currency.format(numBoxes * boxPrice));
        } catch (NumberFormatException e) {
            out.println("That's not a number.");
        }
    }
}

Figure 12-3 shows three runs of the code from Listing 12-2. When a misguided user types three instead of 3, the program maintains its cool by displaying That's not a number. The trick is to enclose the call to Integer.parseInt inside a try clause. When you do this, the computer watches for exceptions when any statement inside the try clause is executed. If an exception is thrown, the computer jumps from inside the try clause to a catch clause below it. In Listing 12-2, the computer jumps directly to the catch (NumberFormatException e) clause. The computer executes the println statement inside the clause, and then marches on with normal processing. (If there were statements in Listing 12-2 after the end of the catch clause, the computer would go on and execute them.)

An entire try-catch assembly, complete with a try clause, catch clause, and what have you, is called a try statement. Sometimes, for emphasis, I call it a try-catch statement.
The parameter in a catch clause

Take a look at the catch clause in Listing 12-2 and pay particular attention to the words (NumberFormatException e). This looks a lot like a method’s parameter list, doesn’t it? In fact, every catch clause is like a little mini-method with its own parameter list. The parameter list always has an exception type name and then a parameter.

In Listing 12-2, I don’t do anything with the catch clause’s e parameter, but I certainly could if I wanted to. Remember, the exception that’s thrown is an object — an instance of the NumberFormatException class. When an exception is caught, the computer makes the catch clause’s parameter refer to that exception object. In other words, the name e stores a bunch of information about the exception. To take advantage of this, you can call some of the exception object’s methods.

```java
} catch (NumberFormatException e) {
    out.println("That's not a number.");
    out.println("Message: " + e.getMessage());
    out.println("Here comes a stack trace: ");
    e.printStackTrace();
    out.println("Did you like the stack trace?");
}
```

With this enhanced catch clause, a run of the inventory program may look like the run shown in Figure 12-4. When you call getMessage, you fetch some detail about the exception. (In Figure 12-4, the detail is the fact that the user mistakenly typed the word three.) When you call printStackTrace, you get a display showing the methods that were running at the moment when the exception was thrown. (In Figure 12-4, the display includes Integer.parseInt and the main method.) Both getMessage and printStackTrace present information to help you find the source of the program’s difficulties.
**Exception types**

So what else can go wrong today? Are there other kinds of exceptions — things that don’t come from the `NumberFormatException` class? Sure, plenty of different exception types are out there. You can even create one of your own. You wanna try? If so, look at Listings 12-3 and 12-4.

**Listing 12-3: Making Your Own Kind of Exception**

```java
class OutOfRangeException extends Exception {
}
```

**Listing 12-4: Using Your Custom Made Exception**

```java
import static java.lang.System.out;
import java.util.Scanner;
import java.text.NumberFormat;

class InventoryC {
    public static void main(String args[]) {
        final double boxPrice = 3.25;
        Scanner myScanner = new Scanner(System.in);
        NumberFormat currency =
            NumberFormat.getCurrencyInstance();

        out.print("How many boxes do we have? ");
        String numBoxesIn = myScanner.next();

        try {
            int numBoxes = Integer.parseInt(numBoxesIn);
            if (numBoxes < 0) {
                throw new OutOfRangeException();
            }

            out.print("The value is ");
            out.println(currency.format(numBoxes * boxPrice));
        } catch (NumberFormatException e) {
            out.println("That's not a number.");
        } catch (OutOfRangeException e) {
            out.println(numBoxesIn);
            out.println("? That's impossible!");
        }
    }
}
```
Listings 12-3 and 12-4 remedy a problem that cropped up in Figure 12-3. Look at the last of the three runs in Figure 12-3. The user reports that the shelves have –25 boxes, and the computer takes this value without blinking an eye. The truth is that you would need a black hole (or some other exotic space-time warping phenomenon) to have a negative number of boxes on any shelf in your warehouse. So the program should get upset if the user enters a negative number of boxes, which is what the code in Listing 12-4 does. To see the upset code, look at Figure 12-5.

The code in Listing 12-3 declares a new kind of exception class — `OutOfRange Exception`. In many situations, typing a negative number would be just fine, so `OutOfRangeException` isn't built into the Java API. However, in the inventory program, a negative number should be flagged as an anomaly.

The `OutOfRangeException` class in Listing 12-3 wins the award for the shortest self-contained piece of code in the book. The class's code is just a declaration line and an empty pair of braces. The code's operative phrase is `extends Exception`. Being a subclass of the Java API `Exception` class allows any instance of the `OutOfRangeException` class to be thrown.

Back in Listing 12-4, a new `OutOfRangeException` instance is thrown. When this happens, the `catch` clause (`OutOfRange e`) catches the instance. The clause echoes the user's input and displays the message `That's impossible!`

**Who's going to catch the exception?**

Take one more look at Listing 12-4. Notice that more than one `catch` clause can accompany a single `try` clause. When an exception is thrown inside a `try` clause, the computer starts going down the accompanying list of `catch` clauses. The computer starts at whatever `catch` clause comes immediately after the `try` clause and works its way down the program's text.
For each `catch` clause, the computer asks itself, “Is the exception that was just thrown an instance of the class in this clause’s parameter list?”

- If not, the computer skips this `catch` clause and moves on to the next `catch` clause in line.
- If so, the computer executes this `catch` clause and then skips past all the other `catch` clauses that come with this `try` clause. The computer goes on and executes whatever statements come after the whole `try-catch` statement.

For some concrete examples, see Listings 12-5 and 12-6.

**Listing 12-5: Yet Another Exception**

```java
class NumberTooLargeException extends OutOfRangeException {
}
```

**Listing 12-6: Where Does the Buck Stop?**

```java
import static java.lang.System.out;
import java.util.Scanner;
import java.text.NumberFormat;

class InventoryD {
    public static void main(String args[]) {
        final double boxPrice = 3.25;
        Scanner myScanner = new Scanner(System.in);
        NumberFormat currency = NumberFormat.getCurrencyInstance();

        out.print("How many boxes do we have? ");
        String numBoxesIn = myScanner.next();

        try {
            int numBoxes = Integer.parseInt(numBoxesIn);

            if (numBoxes < 0) {
                throw new OutOfRangeException();
            }

            if (numBoxes > 1000) {
                throw new NumberTooLargeException();
            }

            out.print("The value is ");
            out.println(currency.format(numBoxes * boxPrice));
        }
    }
}
```

(continued)
Listing 12-6 (continued)

```java
catch (NumberFormatException e) {
    out.println("That's not a number.");
}

catch (OutOfRangeException e) {
    out.print(numBoxesIn);
    out.println("\? That's impossible!");
}

catch (Exception e) {
    out.print("Something went wrong. ");
    out.print("but I'm clueless about what ");
    out.println("it actually was.");
}

    out.println("That's that.");
}
```

To run the code in Listings 12-5 and 12-6, you need one additional Java program file. You need the `OutOfRangeException` class in Listing 12-3.

Listing 12-6 addresses the scenario in which you have limited shelf space. You don’t have room for more than 1,000 boxes, but once in a while, the program asks how many boxes you have, and somebody enters the number `100000` by accident. In cases like this, Listing 12-6 does a quick reality check. Any number of boxes over 1,000 is tossed out as being unrealistic.

Listing 12-6 watches for a `NumberTooLargeException`, but to make life more interesting, Listing 12-6 doesn’t have a catch clause for the `NumberTooLargeException`. In spite of this, everything still works out just fine. It’s fine because `NumberTooLargeException` is declared to be a subclass of `OutOfRangeException`, and Listing 12-6 has a catch clause for the `OutOfRangeException`.

You see, because `NumberTooLargeException` is a subclass of `OutOfRangeException`, any instance of `NumberTooLargeException` is just a special kind of `OutOfRangeException`. So in Listing 12-6, the computer may start looking for a clause to catch a `NumberTooLargeException`. When the computer stumbles upon the `OutOfRangeException` catch clause, the computer says, “Okay, I’ve found a match. I’ll execute the statements in this catch clause.”

To keep from having to write this whole story over and over again, I introduce some new terminology. I say that the catch clause with parameter `OutOfRangeException` matches the `NumberTooLargeException` that’s been thrown. I call this catch clause a matching catch clause.
The following bullets describe different things that the user may do and how the computer responds. As you read through the bullets, you can follow along by looking at the runs shown in Figure 12-6.

- The user enters an ordinary whole number, like the number 3.
  All the statements in the `try` clause are executed. Then the computer skips past all the `catch` clauses and executes the code that comes immediately after all the `catch` clauses. (See Figure 12-7.)

```java
try {
    //Normal processing (throw no exception)
}

catch (NumberFormatException e) {
    out.println("That's not a number.");
}

catch (OutOfRangeException e) {
    out.print(numBoxesIn);
    out.println("? That's impossible!");
}

catch (Exception e) {
    out.print("Something went wrong, ");
    out.print("but I'm clueless about what ");
    out.println("it actually was.");
}

out.println("That's that.");
```

Figure 12-6: Running the code from Listing 12-6.

Figure 12-7: No exception is thrown.
The user enters something that's not a whole number, like the word _fish_.

The code throws a `NumberFormatException`. The computer skips past the remaining statements in the `try` clause. The computer executes the statements inside the first `catch` clause — the clause whose parameter is of type `NumberFormatException`. Then the computer skips past the second and third `catch` clauses and executes the code that comes immediately after all the `catch` clauses. (See Figure 12-8.)

```java
try {
    throw new NumberFormatException();
}

catch (NumberFormatException e) {
    out.println("That's not a number.");
}

catch (OutOfRangeException e) {
    out.print(numBoxesIn);
    out.println("? That's impossible!");
}

catch (Exception e) {
    out.print("Something went wrong, ");
    out.print("but I'm clueless about what ");
    out.println("it actually was.");
}

out.println("That's that.");
```

The user enters a negative number, like the number `–25`.

The code throws an `OutOfRangeException`. The computer skips past the remaining statements in the `try` clause. The computer even skips past the statements in the first `catch` clause. (After all, an `OutOfRangeException` isn't any kind of a `NumberFormatException`. The catch clause with parameter `NumberFormatException` isn't a match for this `OutOfRangeException`.) The computer executes the statements inside the second `catch` clause — the clause whose parameter is of type `OutOfRangeException`. Then the computer skips past the third `catch` clause and executes the code that comes immediately after all the `catch` clauses. (See Figure 12-9.)
The user enters an unrealistically large number, like the number 1001.

The code throws a NumberTooLargeException. The computer skips past the remaining statements in the try clause. The computer even skips past the statements in the first catch clause. (After all, a NumberTooLarge Exception isn’t any kind of NumberFormatException.)

But, according to the code in Listing 12-5, NumberTooLargeException is a subclass of OutOfRangeException. When the computer reaches the second catch clause, the computer says, “Hmm! A NumberTooLarge Exception is a kind of OutOfRangeException. I’ll execute the statements in this catch clause — the clause with parameter of type OutOfRangeException.” In other words, it’s a match.

So, the computer executes the statements inside the second catch clause. Then the computer skips the third catch clause and executes the code that comes immediately after all the catch clauses. (See Figure 12-10.)

Something else, something very unpredictable happens (I don’t know what).

With my unending urge to experiment, I reached into the try clause of Listing 12-6 and added a statement that throws an IOException. No reason — I just wanted to see what would happen.
When the code threw an IOException, the computer skipped past the remaining statements in the try clause. Then the computer skipped past the statements in the first and second catch clauses. When the computer reached the third catch clause, I could hear the computer say, “Hmm! An IOException is a kind of Exception. I’ve found a matching catch clause — a clause with a parameter of type Exception. I’ll execute the statements in this catch clause.”

So, the computer executed the statements inside the third catch clause. Then the computer executed the code that comes immediately after all the catch clauses. (See Figure 12-11.)

When the computer looks for a matching catch clause, the computer latches on to the topmost clause that fits one of the following descriptions:

- The clause’s parameter type is the same as the type of the exception that was thrown.
- The clause’s parameter type is a superclass of the exception’s type.
If a better match appears farther down the list of catch clauses, that's just too bad. For instance, imagine that you added a catch clause with a parameter of type NumberTooLargeException to the code in Listing 12-6. Imagine, also, that you put this new catch clause after the catch clause with parameter of type OutOfRangeException. Then, because NumberTooLargeException is a subclass of the OutOfRangeException class, the code in your new NumberTooLargeException clause would never be executed. That's just the way the cookie crumbles.

Try throwing caution to the wind

Are you one of those obsessive-compulsive types? Do you like to catch every possible exception before the exception can possibly crash your program? Well, watch out. Java doesn't let you become paranoid. You can't catch an exception if the exception has no chance of being thrown.

Consider the following code. The code has a very innocent i++ statement inside a try clause. That's fair enough. But then the code's catch clause is pretending to catch an IOException.
// Bad code!
try {
    i++;
} catch (IOException e) {
    e.printStackTrace();
}

Who is this catch clause trying to impress? A statement like i++ doesn’t do any input or output. The code inside the try clause can’t possibly throw an IOException. So the compiler comes back and says, “Hey, catch clause. Get real. Get off your high horse.” Well, to be a bit more precise, the compiler’s reprimand reads as follows:

```
exception java.io.IOException is never thrown in body of corresponding try statement
```

### Doing useful things

So far, each example in this chapter catches an exception, prints a “bad input” message, and then closes up shop. Wouldn’t it be nice to see a program that actually carries on after an exception has been caught? Well, it’s time for something nice. Listing 12-7 has a try-catch statement inside a loop. The loop keeps running until the user types something sensible.

### Listing 12-7: Keep Pluggin’ Along

```java
import static java.lang.System.out;
import java.util.Scanner;
import java.text.NumberFormat;

class InventoryLoop {
    public static void main(String args[]) {
        final double boxPrice = 3.25;
        boolean gotGoodInput = false;
        Scanner myScanner = new Scanner(System.in);
        NumberFormat currency = NumberFormat.getCurrencyInstance();

        do {
            out.print("How many boxes do we have? ");
            String numBoxesIn = myScanner.next();

            try {
                int numBoxes = Integer.parseInt(numBoxesIn);
                out.print("The value is ");
```
```java
out.println(currency.format(numBoxes * boxPrice));
gotGoodInput = true;
} catch (NumberFormatException e) {
    out.println();
    out.println("That's not a number.");
}
} while (!gotGoodInput);
out.println("That's that.");
```

Figure 12-12 shows a run of the code from Listing 12-7. In the first three attempts, the user types just about everything except a valid whole number. At last, the fourth attempt is a success. The user types 3, and the computer leaves the loop.

<table>
<thead>
<tr>
<th>Configuration:</th>
</tr>
</thead>
<tbody>
<tr>
<td>How many boxes do we have? 3.5</td>

<tr>
<td>How many boxes do we have? three</td>
</tr>
<tr>
<td>That's not a number.</td>
</tr>
<tr>
<td>How many boxes do we have? fish</td>
</tr>
<tr>
<td>That's not a number.</td>
</tr>
<tr>
<td>The value is $9.75</td>
</tr>
<tr>
<td>That's that.</td>
</tr>
<tr>
<td>Process completed.</td>
</tr>
</tbody>
</table>

**Our friends, the good exceptions**

A rumor is going around that Java exceptions always come from unwanted, erroneous situations. Although there’s some truth to this rumor, the rumor isn’t entirely accurate. Occasionally, an exception arises from a normal, expected occurrence. Take, for instance, the detection of the end of a file. The following code makes a copy of a file:

```java
try {
    while (true) {
        dataOut.WriteByte(dataIn.ReadByte());
    }
} catch (EOFException e) {
    numFilesCopied = 1;
}
To copy bytes from `dataIn` to `dataOut`, you just go into a `while` loop. With its `true` condition, the `while` loop is seemingly endless. But eventually, you reach the end of the `dataIn` file. When this happens, the `readByte` method throws an `EOFException` (an end-of-file exception). The throwing of this exception sends the computer out of the `try` clause and out of the `while` loop. From there, you do whatever you want to do in the `catch` clause, and then proceed with normal processing.

**Handle an Exception or Pass the Buck**

So you’re getting to know Java, hey? What? You say you’re all the way up to Chapter 12?

I’m impressed. You must be a hard worker. But remember, all work and no play...

So, how about taking a break? A little nap could do you a world of good. Is ten seconds okay? Or is that too long? Better make it five seconds.

Listing 12-8 has a program that’s supposed to pause its execution for five seconds. The problem is that the program in Listing 12-8 is incorrect. Take a look at Listing 12-8 for a minute, and then I’ll tell you what’s wrong with it.

**Listing 12-8: An Incorrect Program**

```java
/*
 * This code does not compile.
 */

import static java.lang.System.out;

class NoSleepForTheWeary {
    public static void main(String args[]) {
        out.print("Excuse me while I nap ");
        out.println("for just five seconds...");
        takeANap();
        out.println("Ah, that was refreshing.");
    }

    static void takeANap() {
        Thread.sleep(5000);
    }
}
```
The strategy in Listing 12-8 isn’t bad. The idea is to call the `sleep` method, which is defined in the Java API. This `sleep` method belongs to the API `Thread` class. When you call the `sleep` method, the number that you feed it is a number of milliseconds. So, `Thread.sleep(5000)` means pause for five seconds.

The problem is that the code inside the `sleep` method can throw an exception. This kind of exception is an instance of the `InterruptedException` class. When you try to compile the code in Listing 12-8, you get the following unwanted message:

```
unreported exception java.lang.InterruptedException; must be caught or declared to be thrown
```

For the purpose of understanding exceptions in general, you don’t need to know exactly what an `InterruptedException` is. All you really have to know is that a call to `Thread.sleep` can throw one of these `InterruptedException` objects. But if you’re really curious, an `InterruptedException` is thrown when some code interrupts some other code’s sleep. Imagine that you have two pieces of code running at the same time. One piece of code calls the `Thread.sleep` method. At the same time, another piece of code calls the `interrupt` method. By calling the `interrupt` method, the second piece of code brings the first code’s `Thread.sleep` method to a screeching halt. The `Thread.sleep` method responds by spitting out an `InterruptedException`.

Now, the Java programming language has two different kinds of exceptions. They’re called checked and unchecked exceptions:

- The potential throwing of a checked exception must be acknowledged in the code.
- The potential throwing of an unchecked exception doesn’t need to be acknowledged in the code.

An `InterruptedException` is one of Java’s checked exception types. When you call a method that has the potential to throw an `InterruptedException`, you need to acknowledge that exception in the code.

Now, when I say that an exception is acknowledged in the code, what do I really mean?

```
// The author wishes to thank that InterruptedException, without which this code could not have been written.
```

No, that’s not what it means to be acknowledged in the code. Acknowledging an exception in the code means one of two things:
The statements (including method calls) that can throw the exception are inside a `try` clause. That `try` clause has a `catch` clause with a matching exception type in its parameter list.

The statements (including method calls) that can throw the exception are inside a method that has a `throws` clause in its header. The `throws` clause contains a matching exception type.

If you’re confused by the wording of these two bullets, don’t worry. The next two listings illustrate the points made in the bullets.

In Listing 12-9, the method call that can throw an `InterruptedException` is inside a `try` clause. That `try` clause has a `catch` clause with exception type `InterruptedException`.

**Listing 12-9: Acknowledging with a try-catch Statement**

```java
import static java.lang.System.out;

class GoodNightsSleepA {
    public static void main(String args[]) {
        out.print("Excuse me while I nap ");
        out.println("for just five seconds...");
        takeANap();
        out.println("Ah, that was refreshing.");
    }

    static void takeANap() {
        try {
            Thread.sleep(5000);
        } catch (InterruptedException e) {
            out.println("Hey, who woke me up?");
        }
    }
}
```

It’s my custom, at this point in a section, to remind you that a run of Listing Such-and-Such is shown in Figure So-and-So. But the problem here is that Figure 12-13 doesn’t do justice to the code in Listing 12-9. When you run the program in Listing 12-9, the computer displays `Excuse me while I nap for just five seconds`, pauses for five seconds, and then displays `Ah, that was refreshing`. The code works because the call to the `sleep` method, which can throw an `InterruptedException`, is inside a `try` clause. That `try` clause has a `catch` clause whose exception is of type `InterruptedException`. 
So much for acknowledging an exception with a `try-catch` statement. You can acknowledge an exception another way, which is used in Listing 12-10.

**Listing 12-10: Acknowledging with throws**

```java
import static java.lang.System.out;

class GoodNightsSleepB {
    public static void main(String args[]) {
        out.print("Excuse me while I nap ");
        out.println("for just five seconds...");

        try {
            takeANap();
        } catch (InterruptedException e) {
            out.println("Hey, who woke me up?");
        }

        out.println("Ah, that was refreshing.");
    }

    static void takeANap() throws InterruptedException {
        Thread.sleep(5000);
    }
}
```

To see a run of the code in Listing 12-10, refer to Figure 12-13. Once again, Figure 12-13 fails to capture the true essence of the run, but that’s okay. Just remember that in Figure 12-13, the computer pauses for five seconds before it displays “Ah, that was refreshing.”

The important part of Listing 12-10 is in the `takeANap` method’s header. That header ends with `throws InterruptedException`. By announcing that it throws an `InterruptedException`, method `takeANap` passes the buck. What this `throws` clause really says is, “I realize that a statement inside this method has the potential to throw an `InterruptedException`, but I’m not acknowledging the exception in a `try-catch` statement. Java compiler, please don’t
bug me about this. Instead of having a try-catch statement, I’m passing the responsibility for acknowledging the exception to the main method (the method that called the takeANap method).”

Indeed, in the main method, the call to takeANap is inside a try clause. That try clause has a catch clause with a parameter of type InterruptedException. So everything is okay. Method takeANap passes the responsibility to the main method, and the main method accepts the responsibility with an appropriate try-catch statement. Everybody’s happy. Even the Java compiler is happy.

To better understand the throws clause, imagine a volleyball game in which the volleyball is an exception. When a player on the other team serves, that player is throwing the exception. The ball crosses the net and comes right to you. If you pound the ball back across the net, you’re catching the exception. But if you pass the ball to another player, you’re using the throws clause. In essence, you’re saying, “Here, other player. You deal with this exception.”

A statement in a method can throw an exception that’s not matched by a catch clause. This includes situations in which the statement throwing the exception isn’t even inside a try block. When this happens, execution of the program jumps out of the method that contains the offending statement. Execution jumps back to whatever code called the method in the first place.

A method can name more than one exception type in its throws clause. Just use commas to separate the names of the exception types, like in the following example:

```java
throws InterruptedException, IOException, ArithmeticException
```

The Java API has hundreds of exception types. Several of them are subclasses of the RuntimeException class. Anything that’s a subclass of RuntimeException (or a sub-subclass, sub-sub-subclass, and so on) is unchecked. Any exception that’s not a descendent of RuntimeException is checked. The unchecked exceptions include things that would be hard for the computer to predict. Such things include the NumberFormatException (of Listings 12-2, 12-4, and others), the ArithmeticException, the IndexOutOfBoundsException, the infamous NullPointerException, and many others. When you write Java code, much of your code is susceptible to these exceptions, but enclosing the code in try clauses (or passing the buck with throws clauses) is completely optional.

The Java API also has its share of checked exceptions. The computer can readily detect exceptions of this kind. So Java insists that, for an exception of this kind, any potential exception-throwing statement is acknowledged with
either a try statement or a throws clause. Java’s checked exceptions include the InterruptedException (Listings 12-9 and 12-10), the IOException, the SQLException, and a gang of other interesting exceptions.

**Finishing the Job with a finally Clause**

Once upon a time, I was a young fellow, living with my parents in Philadelphia, just starting to drive a car. I was heading toward a friend’s house and thinking about who knows what when another car came from nowhere and bashed my car’s passenger door. This kind of thing is called a RunARedLightException.

Anyway, both cars were still drivable, and we were right in the middle of a busy intersection. To avoid causing a traffic jam, we both pulled over to the nearest curb. I fumbled for my driver’s license (which had a very young picture of me on it), and opened the door to get out of my car.

And that’s when the second accident happened. As I was getting out of my car, a city bus was coming by. The bus hit me and rolled me against my car a few times. This kind of thing is called a DealWithLawyersException.

The truth is that everything came out just fine. I was bruised but not battered. My parents paid for the damage to the car, so I never suffered any financial consequences. (I managed to pass on the financial burden by putting the RunARedLightException into my throws clause.)

This incident helps to explain why I think the way I do about exception handling. In particular, I wonder, “What happens if, while the computer is recovering from one exception, a second exception is thrown?” After all, the statements inside a catch clause aren’t immune to calamities.

Well, the answer to this question is anything but simple. For starters, you can put a try statement inside a catch clause. This protects you against unexpected, potentially embarrassing incidents that can crop up during the execution of the catch clause. But when you start worrying about cascading exceptions, you open up a very slimy can of worms. The number of scenarios is large, and things can become complicated very quickly.

One not-too-complicated thing that you can do is to create a finally clause. Like a catch clause, a finally clause comes after a try clause. The big difference is that the statements in a finally clause are executed whether or not an exception is thrown. The idea is, “No matter what happens, good or bad, execute the statements inside this finally clause.” Listing 12-11 has an example.
Listing 12-11: Jumping Around

```java
import static java.lang.System.out;

class DemoFinally {
    public static void main(String args[]) {
        try {
            doSomething();
        } catch (Exception e) {
            out.println("Exception caught in main.");
        }
    }

    static void doSomething() {
        try {
            out.println(0 / 0);
        } catch (Exception e) {
            out.println("Exception caught in doSomething.");
            out.println(0 / 0);
        } finally {
            out.println("I'll get printed.");
        }
        out.println("I won't get printed.");
    }
}
```

Normally, when I think about a try statement, I think about the computer recovering from an unpleasant situation. The recovery takes place inside a catch clause, and then the computer marches on to whatever statements come after the try statement. Well, if something goes wrong during execution of a catch clause, this picture can start looking different.

Listing 12-11 gets a workout in Figure 12-14. First, the main method calls doSomething. Then, the stupid doSomething method goes out of its way to cause trouble. The doSomething method divides 0 by 0, which is illegal and undoable in anyone's programming language. This foolish action by the doSomething method throws an ArithmeticException, which is caught by the try statement’s one and only catch clause.

<table>
<thead>
<tr>
<th>General Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration</td>
</tr>
<tr>
<td>Exception caught in doSomething.</td>
</tr>
<tr>
<td>I'll get printed</td>
</tr>
<tr>
<td>Exception caught in main.</td>
</tr>
<tr>
<td>Process completed.</td>
</tr>
</tbody>
</table>
Inside the catch clause, that lowlife doSomething method divides 0 by 0 again. This time, the statement that does the division isn’t inside a protective try clause. That’s okay, because an ArithmeticException isn’t checked. (It’s one of those RuntimeException subclasses. It’s an exception that doesn’t have to be acknowledged in a try or a throws clause. For details, see the previous section.)

Well, checked or not, the throwing of another ArithmeticException causes control to jump out of the doSomething method. But, before leaving the doSomething method, the computer executes the try statement’s last will and testament — namely, the statements inside the finally clause. That’s why, in Figure 12-14, you see the words I’ll get printed.

Interestingly enough, you don’t see the words I won’t get printed in Figure 12-14. Because the catch clause’s execution throws its own uncaught exception, the computer never makes it down past the try-catch-finally statement.

So, the computer goes back to where it left off in the main method. Back in the main method, word of the doSomething method’s ArithmeticException mishaps causes execution to jump into a catch clause. The computer prints Exception caught in main, and then this terrible nightmare of a run is finished.
Part V
The Part of Tens

The 5th Wave
By Rich Tennant

“I’ve been in hardware all of my life, and all of a sudden it’s software that’ll make me rich.”
In this part . . .

You’re near the end of the book, and the time has come to sum it all up. This part of the book is your slam-bam, two-thousand-words-or-less resource for Java. What? You didn’t read every word in the chapters before this one? That’s okay. You can pick up a lot of useful information in this Part of Tens.
In This Chapter

- Checking your capitalization and value comparisons
- Watching out for fall-through
- Putting methods, listeners, and constructors where they belong
- Using static and nonstatic references
- Avoiding other heinous errors

"The only people who never make mistakes are the people who never do anything at all." One of my college professors said that. I don't remember the professor's name, so I can't give him proper credit. I guess that's my mistake.

Putting Capital Letters Where They Belong

Java is a case-sensitive language, so you really have to mind your Ps and Qs — along with every other letter of the alphabet. Here are some things to keep in mind as you create Java programs:

- Java’s keywords are all completely lowercase. For instance, in a Java if statement, the word if can’t be If or IF.
- When you use names from the Java API (Application Programming Interface), the case of the names has to match what appears in the API.
- You also need to make sure that the names you make up yourself are capitalized the same way throughout your entire program. If you declare a myAccount variable, you can’t refer to it as MyAccount, myaccount, or Myaccount. If you capitalize the variable name two different ways, Java thinks you’re referring to two completely different variables.

For more info on Java’s case-sensitivity, see Chapter 3.
Breaking Out of a switch Statement

If you don’t break out of a `switch` statement, you get fall-through. For instance, if the value of `verse` is 3, the following code prints all three lines — Last refrain, He's a pain, and Has no brain.

```java
switch (verse) {
    case 3:
        out.print("Last refrain, ");
        out.println("last refrain.");
    case 2:
        out.print("He's a pain, ");
        out.println("he's a pain.");
    case 1:
        out.print("Has no brain, ");
        out.println("has no brain.");
}
```

For the full story, see Chapter 5.

Comparing Values with a Double Equal Sign

When you compare two values with one another, you use a double equal sign. The line

```java
if (inputNumber == randomNumber)
```

is correct, but the line

```java
if (inputNumber = randomNumber)
```

is not correct. For a full report, see Chapter 5.

Adding Components to a GUI

Here’s a constructor for a Java frame:

```java
public SimpleFrame() {
    JButton button = new JButton("Thank you...");
    setTitle("...Steven Hayes and Virginia Sanders");
    setLayout(new FlowLayout());
}
```
Whatever you do, don’t forget the call to the `add` method. Without this call, you go to all the work of creating a button, but the button doesn’t show up on your frame. For an introduction to such issues, see Chapter 9.

### Adding Listeners to Handle Events

Look again at the previous section’s code to construct a `SimpleFrame`. If you forget the call to `addActionListener`, nothing happens when you click the button. Clicking the button a second time and clicking it harder don’t help. For the rundown on listeners, see Chapter 16, which is on the CD-ROM.

### Defining the Required Constructors

When you define a constructor with parameters, as in

```java
public Temperature(double number)
```

then the computer no longer creates a default parameterless constructor for you. In other words, you can no longer call

```java
Temperature roomTemp = new Temperature();
```

unless you explicitly define your own parameterless `Temperature` constructor. For all the gory details on constructors, see Chapter 9.

### Fixing Non-Static References

If you try to compile the following code, you get an error message:

```java
class WillNotWork {
    String greeting = "Hello";

    public static void main(String args[]) {
        System.out.println(greeting);
    }
}
```
Staying within Bounds in an Array

When you declare an array with ten components, the components have indices 0 through 9. In other words, if you declare

```java
int guests[] = new int[10];
```

then you can refer to the guests array’s components by writing guests[0], guests[1], and so on, all the way up to guests[9]. You can’t write guests[10], because the guests array has no component with index 10.

For the latest gossip on arrays, see Chapter 11.

Anticipating Null Pointers

This book’s examples aren’t prone to throwing the NullPointerException, but in real-life Java programming, you see that exception all the time. A NullPointerException comes about when you call a method that’s supposed to return an object, but instead the method returns nothing. Here’s a cheap example:

```java
import static java.lang.System.out;
import java.io.File;

class ListMyFiles {
    public static void main(String args[]) {
        File myFile = new File("\windows");

        String dir[] = myFile.list();

        for (String fileName : dir) {
            out.println(fileName);
        }
    }
}
```

This program displays a list of all the files in the windows directory. (For clarification on the use of the double backslash in "\windows", see Chapter 8.)
But what happens if you change `windows` to something else — something that doesn’t represent the name of a directory?

```java
File myFile = new File("&*%$!!");
```

Then the `new File` call returns `null` (a special Java word meaning “nothing”) so the variable `myFile` has nothing in it. Later in the code, the variable `dir` refers to nothing, and the attempt to loop through all the `dir` values fails miserably. You get a big `NullPointerException`, and the program comes crashing down around you.

To avoid this kind of calamity, check Java’s API documentation. If you’re calling a method that can return `null`, add exception-handling code to your program.

For the story on handling exceptions, see Chapter 12. For some advice on reading the API documentation, see Chapter 3 and this book’s Web site.

**Helping Java Find its Files**

You’re compiling Java code, minding your own business, when the computer gives you a `NoClassDefFoundError`. All kinds of things can be going wrong, but chances are that the computer can’t find a particular Java file. To fix this, you must align all the planets correctly.

✔ Your project directory has to contain all the Java files whose names are used in your code.

✔ If you use named packages, your project directory has to have appropriately named subdirectories.

✔ Your CLASSPATH must be set properly.

For specific guidelines, see Chapter 15 (on the CD-ROM) and this book’s Web site.
Chapter 14

Ten Sets of Web Resources for Java

In This Chapter
- Finding resources from Sun Microsystems
- Getting sample code
- Reading the latest Java news
- Starting out — help for Java beginners
- Moving up — jobs, certification, and more for experienced programmers

No wonder the Web is so popular. It’s both useful and fun. This chapter has ten bundles of resources. Each bundle has Web sites for you to visit. Each Web site has resources to help you use Java more effectively. And as far as I know, none of these sites uses adware, pop-ups, or other grotesque things.

The Horse’s Mouth

Sun’s official Web site for Java is java.sun.com. This site has all the latest development kits, and many of them are free. In addition, Sun has two special-purpose Java Web sites. Consumers of Java technology should visit www.java.com. Programmers and developers interested in sharing Java technology can go to www.java.net.

And be sure to visit www.jcp.org, home of the Java Community Process. At this site, you can read the latest proposals for improving Java. Who knows? You may even want to contribute.
Finding News, Reviews, and Sample Code

The Web has plenty of sites devoted exclusively to Java. Many of these sites feature reviews, links to other sites, and best of all, oodles of sample Java code. Some also offer free mailing lists that keep you informed of the latest Java developments. Here’s a brief list of such sites:

- The JavaRanch: www.javaranch.com
- Gamelan: www.developer.com/java
- The Giant Java Tree: www.gjt.org
- The Java Boutique: javaboutique.internet.com
- Freewarejava.com: www.freewarejava.com
- JavaToys: www.nikos.com/javatoys
- JavaShareware.com: www.javashareware.com

Improving Your Code with Tutorials

To find out more about Java, you can visit Sun’s online training pages. The Web address is java.sun.com/developer/onlineTraining. Some other nice tutorials are available at the following Web sites:

- Richard Baldwin’s Web site: www.dickbaldwin.com
- ProgrammingTutorials.com: www.programmingtutorials.com

Finding Help on Newsgroups

Have a roadblock that you just can’t get past? Try posting your question on an Internet newsgroup. Almost always, some friendly expert posts just the right reply.
With or without Java, you should definitely start exploring newsgroups. You can find thousands of newsgroups — groups on just about every conceivable topic. (Yes, there are more newsgroups than *For Dummies* titles!) To get started with newsgroups, visit groups.google.com. For postings specific to Java, look for the groups whose names begin with comp.lang.java. For a novice, the following three groups are probably the most useful:

- comp.lang.java.programmer
- comp.lang.java.help
- comp.lang.java.gui

### Checking the FAQs for Useful Info

Has the acronym FAQ made it to the Oxford English Dictionary yet? Everybody seems to be using FAQ as an ordinary English word. In case you don’t already know, FAQ stands for *frequently asked questions*. In reality, an FAQ should be called ATQTWTOSPOTN. This acronym stands for *Answers to Questions That We’re Tired of Seeing Posted on This Newsgroup*.

You can find several FAQs at the official Sun Web site. You can also check out the FAQs for the comp.lang.java newsgroups that I discuss in the previous section. To read this wealth of information, go to www.afu.com/javafaq.html.

### Opinions and Advocacy

Java isn’t just techie stuff. The field has issues and opinions of all shapes and sizes. To find out more about them, visit www.javalobby.org. After you’ve hovered for a while and have a feel for the etiquette, you can even join the discussion.

### Looking for Java Jobs

Are you looking for work? Would you like to have an exciting, lucrative career as a Java programmer? Then try visiting a Web site that’s specially designed for people like you. Point your Web browser to www.javajobs.com or java.computerwork.com.
Becoming Certified in Java

These days, everybody is anxious to become certified. If you’re one of these people, you can find plenty of resources about Java certification on the Web. Just start by visiting www.javaprepare.com and www.javaranch.com/ring.jsp. Both of these sites link to other interesting sites, including sites with practice certification exams.

Developing Servlets

This book has all the tools that you need to start using Java. When you’ve finished being started, you may want to start continuing. This may involve writing Java servlets.

A servlet is program that responds to a Web request. For instance, a user sitting at a computer in Ong’s Hat, New Jersey, clicks a link. The link-click is sent to a host computer in Chicken, Alaska. Sophisticated as it is, that host computer in Chicken composes an entire Web page on the fly. The host computer sends the newly composed page back to the visitor’s computer in Ong’s Hat, New Jersey.

Composing a Web page on the fly is something that you can do with a Java servlet. The only extra thing that you need is a cooperative host computer. Fortunately for cheapskates, you can use some host computers for free. For lists of servlet-enabled hosts, visit www.coolservlets.com/hosts.html and www.servlets.com/isps/servlet/ISPViewAll.

Everyone’s Favorite Sites

It’s true — these two sites aren’t devoted exclusively to Java. However, no geek-worthy list of resources would be complete without Slashdot and SourceForge.

Slashdot’s slogan, “News for nerds, stuff that matters,” says it all. At slashdot.org you find news, reviews, and commentary on almost anything related to computing. There’s even a new word to describe a Web site that’s reviewed or discussed on the Slashdot site. When a site becomes overwhelmed with hits from Slashdot referrals, one says that the site has been slashdotted.
Although it’s not quite as high-profile, sourceforge.net is the place to look for open source software of any kind. The SourceForge repository contains over 80,000 projects. At the SourceForge site, you can download software, read about works in process, contribute to existing projects, and even start a project of your own. SourceForge is a great site for programmers and developers at all levels of experience.
Part VI

Appendixes

The 5th Wave
By Rich Tennant

Oh come on—how fatal can it be?
In this part . . .

Appendix A tells you how to use the book’s CD-ROM. And, by the way, if you haven’t cracked open the seal on the book’s CD-ROM yet, please do so. (Of course, you should pay for the book first.) The CD-ROM has some wonderful things on it — all the code from the book, a special customized version of JCreator, some fun shareware, plus a few additional chapters!

Appendix B covers some important material on the use of names in Java programs. Appendix B also features some of my favorite figures and illustrations, so (please) spend a few minutes with this appendix.
Sure, you can read, read, read until your eyes bug out. But you won’t get to know Java until you write and run some code. Besides, it’s no fun to just read about programming. You’ve got to experiment, try things, make some mistakes, and discover some things on your own.

So this book’s CD-ROM has everything you need to get going interactively. First, read the little warning about all the legal consequences of your breaking the seal on this book’s disc pack. Then, throw caution to the wind and rip that pack open. Put the CD-ROM in the drive, and you’re ready to go.

What You Can Expect to Find on the CD-ROM

This CD-ROM has four kinds of files on it:

- **Files that I, the author, created:** For the most part, these files contain all the listings in this book (Listing 3-1 in Chapter 3, for instance). Most of these listings are Java program files.

- **The JCreator integrated development environment:** A free copy of the software, specially customized for this book.
Extra chapters in PDF format: When I start writing, I can’t stop. Eventually, the folks at Wiley Publishing ran out of paper, so they put additional chapters on the CD-ROM.

Various pieces of freeware, shareware, and whateverware: I generally lapse into laziness and call all these things by the name shareware, but the legal department tells me that I should be more careful.

System Requirements

Your system requirements depend on the kind of computer that you have and the kind of operating system that you use. To run the Java 5.0 Software Development Kit on a typical Windows computer, you need at least the following resources:

- A Pentium II processor. (A processor that’s older and clunkier than a Pentium II may be okay, but I make no guarantees.)
- Microsoft Windows (98, Me, 2000, XP, or Server 2003).
- Enough RAM, whatever that means. The official word from Sun Microsystems isn’t specific about this, but I suspect that 128MB is the bare minimum.
- You’d better have a CD-ROM drive. Otherwise, you’ll have difficulty grabbing software off this book’s CD-ROM.
- For the basic tools to write and run your own Java programs, you need about 140MB of disk space. (If you want to store Sun’s documentation, the source files, demos, and other goodies, you need over 400MB.)

If your computer doesn’t match up to most of these requirements, you may have problems getting your Java programs to run. But remember, “may have problems” doesn’t mean that Java won’t work. For the latest and greatest information on Windows configurations, visit java.sun.com/j2se/1.5.0/install-windows.html. (And be prepared to change 1.5.0 in the Web address to 1.5.something-else. These version numbers are moving targets.)

If you’re not a fan of Microsoft Windows, visit java.sun.com/j2se/1.5.0/system-configurations.html for a list of supported system configurations. (Once again, be prepared to change 1.5.0 to 1.5.something-else.)

Additional Java compiler versions (versions for computers not officially supported by the folks at Sun Microsystems) appear frequently on the Web. So if your computer runs Macintosh OS, OpenVMS, or FLKOS (Fred’s Little Known Operating System), search the Web for the compiler that you need. Who knows? You may just find it.
If you find nothing at one of these 1.5.0 Web addresses, change the number in the address to 1.5.\textit{something-else}. Maybe they’re up to Java version 1.5.0\_02 or even 1.5.1. Of course, if you can’t find the correct Web address, and you don’t enjoy guessing games, you have another alternative. Pay a visit to this book’s Web site. At that site, I (try to) keep a fairly up-to-date list of useful Java links.

Finally, if you need more information on basic hardware and software issues, check out these books published by Wiley Publishing, Inc.: \textit{PCs For Dummies}, by Dan Gookin; \textit{Macs For Dummies}, by David Pogue; \textit{Windows 2000 Professional For Dummies}, by Andy Rathbone and Sharon Crawford; and \textit{Windows 98 For Dummies, Microsoft Windows ME Millennium Edition For Dummies}, and \textit{Windows XP For Dummies}, all by Andy Rathbone.

\section*{Using the CD with Microsoft Windows}

To install items from the CD to your hard drive (with the Autorun feature enabled), follow these steps:

1. \textbf{Insert the CD into your computer’s CD-ROM drive.}
   
   A window appears with the following options: HTML Interface, Browse CD, and Exit.

2. \textbf{Select one of the options, as follows:}
   
   \begin{itemize}
   \item \textbf{HTML Interface}: Click this button to view the contents of the CD in standard \textit{For Dummies} presentation. It looks like a Web page. Here you can also find a list of useful Web links from the book.
   \item \textbf{Browse CD}: Click this button to skip the fancy presentation and simply view the CD contents from the directory structure. This means that you see just a list of folders — plain and simple.
   \item \textbf{Exit}: Well, what can I say? Click this button to quit.
   \end{itemize}

If you don’t have the Autorun feature enabled, or if the Autorun window doesn’t appear, follow these steps to access the CD:

1. \textbf{Insert the CD into your computer’s CD-ROM drive.}

2. \textbf{Click the Start button and choose Run from the menu.}

3. \textbf{In the dialog box that appears, type d:\start.htm.}

   Replace \textit{d} with the proper drive letter for your CD-ROM if it uses a different letter. (If you don’t know the letter, double-click the My Computer icon on your desktop and see what letter is listed for your CD-ROM drive.)

   Your browser opens, and the license agreement appears. If you don’t have a browser, Microsoft Internet Explorer is included on the CD.
4. Read through the license agreement, nod your head, and click the Agree button if you want to use the CD.

After you click Agree, you’re taken to the Main menu, where you can browse through the contents of the CD.

5. To navigate within the interface, click a topic of interest to take you to an explanation of the files on the CD and how to use or install them.

6. To install software from the CD, simply click the software name.

You see two options: to run or open the file from the current location or to save the file to your hard drive. Choose to run or open the file from its current location, and the installation procedure continues. When you finish using the interface, close your browser as usual.

Note: I’ve included an “easy install” in these HTML pages. If your browser supports installations from within it, go ahead and click the links of the program names you see. You see two options: Run the File from the Current Location and Save the File to Your Hard Drive. Select the Run the File from the Current Location option and the installation procedure continues. A Security Warning dialog box appears. Click Yes to continue the installation.

Using the CD with Mac OS

To install items from the CD to your hard drive, follow these steps:

1. Insert the CD into your computer’s CD-ROM drive.

In a moment, an icon representing the CD that you just inserted appears on your Mac desktop. Chances are that the icon looks like a CD-ROM.

2. Double-click the CD icon to show the CD’s contents.

3. Double-click start.htm to open your browser and display the license agreement.

If your browser doesn’t open automatically, open it as you normally would by choosing File ➪ Open File (in Internet Explorer) or File ➪ Open ➪ Location in Netscape and select Java 2 For Dummies. The license agreement appears.

4. Read through the license agreement, nod your head, and click the Accept button if you want to use the CD.

After you click Accept, you’re taken to the Main menu. This is where you can browse through the contents of the CD.

5. To navigate within the interface, click any topic of interest, and you’re taken you to an explanation of the files on the CD and how to use or install them.

6. To install software from the CD, simply click the software name.
Running the Java Code That’s in This Book

The CD-ROM has all the code from the listings in this book. It also has some helper files (data files and other things) that you need to make the most of all the listings.

If you install JCreator from the CD-ROM, all the code from the book’s listings gets installed automatically. The code is installed in JCreator’s MyProjects directory on your computer’s hard drive. For details, see Chapter 2.

If you don’t install JCreator from the CD-ROM, you can still copy this book’s code to your computer’s hard drive. Just navigate to the folder named Author on the CD-ROM. Copy everything in that Author folder to your hard drive.

I’ve tried to organize the book’s listings in a simple, yet sensible way. I thought a long time and came up with a grand plan. The plan is pretty intuitive, so you can either read about the plan or just follow your nose. Personally I like noses, but you may like the security of having neatly printed rules. If you want rules, I present them right here:

- If you use JCreator, all the code is in subdirectories of the MyProjects directory. (See Chapter 2.)

- Each example has its own subdirectory, and each subdirectory constitutes a single project. For instance, the code from Listing 3-1 is in its own little directory named Listing0301. The tree in JCreator’s File View pane has a branch labeled Listing0301.

- In some cases, several of the book’s listings combine to make one big example. In such cases, that example’s subdirectory has a big combined name. For instance, in Chapter 7, you get the first full example when you compile and run Listings 7-1 and 7-2. So the directory for this example is named Listings0701-02. The tree in JCreator’s File View pane has a branch labeled Listings0701-02.

- As a rule of thumb, when a listing’s code begins with class SomeName, the code is in a file called SomeName.java.

- Examples are grouped by chapter, and each chapter has its own JCreator workspace.

  For instance, JCreator’s MyProjects directory has subdirectories named Listing0501, Listing0502, Listing0601, and so on. The MyProjects directory also has files named Chapter05.jcw, Chapter06.jcw, and so on.

  If you choose File ➤ Open Workspace, and select Chapter05.jcw (or just plain Chapter05), you open the Chapter 5 workspace. After doing this, you don’t see Listing0601 in JCreator’s File View pane. You see only the projects named Listing0501, Listing0502, Listing0503, and so on.
Freeware, Shareware, and Just Plain Ware

The following sections provide a summary of the software and other goodies that you can find on the CD. If you need help with installing the items provided on the CD, refer to the installation instructions in the preceding section.

Shareware programs are fully functional, free, trial versions of copyrighted programs. If you like particular programs, register with their authors for a nominal fee and receive licenses, enhanced versions, and technical support. Freeware programs are free, copyrighted games, applications, and utilities. You can copy them to as many computers as you like — for free — but they offer no technical support. GNU software is governed by its own license, which is included inside the folder of the GNU software. The distribution of GNU software is not restricted. See the GNU license at the root of the CD for more details. Trial, demo, or evaluation versions of software are usually limited either by time or functionality (such as not letting you save a project after you create it).

JCreator

Special edition

For Windows. When I started working on this book’s second edition, I went looking for the right Java development environment. I needed something that satisfies all your needs:

- **Easy to use**: You want to use Java. You don’t want to memorize thousands of ways to point and click.
- **Powerful**: You want a scalable tool. As you write bigger and better programs, you want an environment that can support your growing, complex requirements.
- **Efficient**: Memory hogs and CPU hogs need not apply.
- **Inexpensive**: Hey, how about free?
- **Versatile**: In May of 2004, very few development environments supported the enhancements in the upcoming Java version 5.0. I needed a tool that supports all the enhancements, without concession or compromise.

I found all these qualities in only one product: JCreator from Xinox Software.
As if this list of demands wasn’t enough, I needed a company that could work with me to customize its tool. Based on the book’s examples, I had certain specialized needs. I wanted to change this default here and change that option there. I wanted to install my book’s code along with the development environment. Once again, the people at Xinox Software came through for me.

JCreator is a wonderful product. I hope that you enjoy using it.

For more information and a free trial of JCreator PRO, visit www.jcreator.com.

Adobe Acrobat Reader

Commercial version

For Windows and Mac. Talk about added value! This book has several extra chapters on its CD-ROM. To view these chapters, you need a program called Adobe Acrobat Reader. That’s no problem, because a free copy of Reader is on the CD-ROM.

For more information, visit www.adobe.com/acrobat.

If you’re on the road, and you need some light reading, just pull into a nearby cybercafe. You can find the extra chapters on this book’s Web site.

Jindent

Trial version

Platform independent. When it comes to writing code, beauty is more than skin deep. An ugly program is hard to read. If anything goes wrong, no one, not even the program’s author, can wade through lines and lines of cryptic, poorly formatted classes and methods.

To make code look good, you can follow some clear, uniform style guidelines. Always indent by a certain number of spaces, always arrange curly braces a certain way, always do this, never do that. You can memorize lots of rules, or you can have software do it for you.

So write code any way that you want. Then hand your code over to Jindent. The Jindent program beautifies your code, making it easier to read, easier to understand, and (yes!) cheaper to maintain.

For more information, visit www.jindent.com.
**NetCaptor**

Freeware version

*For Windows.* Talk about cool software! When I use someone else’s computer and have to surf without NetCaptor, I feel terribly inconvenienced. NetCaptor uses tabs to keep track of several open Web pages. These tabs replace the need to open several browser windows. So when I visit a search engine, I keep the results page open while I investigate some of the page’s entries. When I do Java development, I keep the API documentation open while I visit one or more of my own documents. Without NetCaptor, I can open several browser windows. However, the interface isn’t as seamless, and the stress on my computer’s RAM and CPU is greater.

For more information, visit [www.netcaptor.com](http://www.netcaptor.com).

**WinOne**

Evaluation

*For Windows.* If you use Windows, and you’re a real geek, you know how clumsy MS-DOS can be. The years I’ve wasted retying commands is dwarfed only by the time that I’ve spent drilling for items in deeply-nested menus and Explorer trees. To make your life simpler, try WinOne. The WinOne shell is like the built-in Windows command prompt. But WinOne has multicolored text, smart filename completion, a scroll bar, command grouping, smart delete, macros, command history, extended batch commands, and (best of all) delightfully easy access to directories.

**And If You Run into Any Trouble . . .**

I tried my best to find shareware programs that work on most computers with the minimum system requirements. Alas, your computer may differ, and some programs may not work properly for some reason.

If you have problems with the shareware on this CD-ROM, the two likeliest problems are that you don’t have enough memory (RAM) or that you have other programs running that are affecting installation or running of a program. If you get an error message such as Not enough memory or Setup cannot continue, try one or more of the following suggestions and then try using the software again:
 ✓ **Turn off any antivirus software running on your computer.** Installation programs sometimes mimic virus activity and may make your computer incorrectly believe that a virus is infecting it.

 ✓ **Close all running programs.** The more programs that you have running, the less memory is available to other programs. Installation programs typically update files and programs. So if you keep other programs running, installation may not work properly.

 ✓ **Have your local computer store add more RAM to your computer.** This is, admittedly, a drastic and somewhat expensive step. However, adding more memory can really help the speed of your computer and allow more programs to run at the same time.

If you still have trouble installing the items from the CD, please call the Wiley Publishing, Inc. Customer Service phone number at 800-762-2974 (outside the U.S.: 317-572-3993) or send an e-mail to the address of your choice: Java2ForDummies@BurdBrain.com or techsupdum@wiley.com.
In Java, the words *public* and *private* are called access modifiers. In this appendix, you get a brief overview of the way that access modifiers work. For more details, see Chapter 15 on the CD-ROM.

**Members versus Classes**

Here's a fake piece of Java code:

```java
class MyClass {
    int myVariable;       // an instance variable
                           // (a member)

                           // a method (another member)
    void myMethod() {
        int myOtherVariable;   // a method-local variable
                                // (not a member)
    }
}
```

There are two kinds of variables — instance variables and method-local variables. This appendix isn’t about method-local variables. It’s about methods and instance variables. Both methods and instance variables are called *members* of a class.
In Java, the word public has two slightly different meanings — one meaning for members and another meaning for classes. Most of this appendix deals with the meaning of public (and of other such words) for members. The last part of this appendix (appropriately titled “Access Modifiers for Classes”) deals with the meaning of public for classes.

**Access Modifiers for Members**

Can you use a certain member name in a particular place in your code? To answer the question, you check to see whether that place is inside or outside of the member’s class:

- If the member is private, only code that’s inside the member’s class can refer directly to that member’s name.

```java
class SomeClass {
    private int myVariable = 10;
}
class SomeOtherClass {
    public static void main(String args[]) {
        SomeClass someObject = new SomeClass();

        // This doesn't work:
        System.out.println(someObject.myVariable);
    }
}
```

- If the member is public, any code can refer directly to that member’s name.

```java
class SomeClass {
    public int myVariable = 10;
}
class SomeOtherClass {
    public static void main(String args[]) {
        SomeClass someObject = new SomeClass();

        // This works:
        System.out.println(someObject.myVariable);
    }
}
```

Figures B-1 through B-3 illustrate the ideas in a slightly different way.
Figure B-1: Several classes and their subclasses.

Figure B-2: The range of code in which a public variable or method can be used (shaded).
**Default access**

No doubt you’ve seen variables and methods with no access modifiers in their declarations. A method or variable of this kind is said to have *default access*. In Java, the default access for a member of a class is package-wide access. A member declared without the word `public`, `private`, or `protected` in front of it is accessible in the package in which its class resides. Figures B-4 and B-5 illustrate the point.

---

**Protected access**

Yet another access modifier isn’t used in any example before this appendix. (At least, I don’t remember using it in any earlier examples.) It’s the *protected* access modifier. A member that’s protected is slightly *less* hidden than one that has default access.
Figure B-4: Packages cut across subclass hierarchies.

Legend:
- A package
- Another package
- Yet another package

Figure B-5: The range of code in which a default variable or method can be used (shaded).

Legend:
- A package
- Another package
- Yet another package
If a member has default access, code in a different package cannot refer directly to that member’s name. The following example illustrates this scenario:

**In one file:**

```java
class SomeClass {
    static int myVariable = 10;
}
```

**And in another file:**

```java
class SomeOtherClass {
    public static void main(String args[]) {
        //This doesn't work:
        System.out.println(myVariable);
    }
}
```

If a member is protected, code in a subclass can refer directly to that member’s name, even if that subclass belongs to a different package. The following example illustrates this particular scenario:

**In one file:**

```java
class SomeClass {
    protected static int myVariable = 10;
}
```

**And in another file:**

```java
class SomeOtherClass {
    public static void main(String args[]) {
        //This works:
        System.out.println(myVariable);
    }
}
```
Looking at this code, you see that you start with an instance variable that has default access (a variable without the word `public`, `private`, or `protected` in its declaration). That variable can be accessed only inside the package in which it lives. Now add the word `protected` to the front of the variable's declaration. Suddenly, classes outside that variable's package have some access to the variable. A subclass (of the class in which the variable is declared) can now reference the variable. You can also reference the variable from a sub-subclass, a sub-sub-subclass, and so on. Any descendant class will do.

Compare Figures B-5 and B-6. Notice the extra bit of shading in Figure B-6? A subclass can access a protected member of a class, even if that subclass belongs to some other package.

The real story about protected access is one step more complicated than the story that I describe in this section. The Java Language Specification mentions a hair-splitting point about code being responsible for an object's implementation. When you're first figuring out how to program in Java, don't worry about this point. Wait until you've written many Java programs. Then, when you stumble upon a variable has protected access error message, you can start worrying. Better yet, skip the worrying and take a careful look at the protected access section in the Java Language Specification.
**Access Modifiers for Classes**

A class can be either public or non-public. If you see something like

```
public class SomeClass
```

then you’re looking at the declaration of a public class. But, if you see plain old

```
class SomeClass
```

then the class that’s being declared isn’t public.

If a class is public, you can refer to the class from anywhere in your code. The following example illustrates the point:

**In one file:**

```
package com.burdbrain.somepackage;

public class SomeClass {
}
```

**And in another file:**

```
package com.burdbrain.someotherpackage;

import com.burdbrain.somepackage.*;

//You CAN extend SomeClass:
class SomeOtherClass extends SomeClass {
    public static void main(String args[]) {
        //This works too:
        SomeClass someObject = new SomeClass();
    }
}
```

If a class isn’t public, you can refer to the class only from code within the class’s package. The following code makes that crystal clear:

**In one file:**

```
package com.burdbrain.somepackage;

class SomeClass {
}
```
And in another file:

```java
package com.burdbrain.someotherpackage;
import com.burdbrain.somepackage.*;

// You can't extend SomeClass:
class SomeOtherClass extends SomeClass {
    public static void main(String args[]) {
        // This doesn't work either:
        SomeClass someObject = new SomeClass();
    }
}
```

Chapter 15

Sharing Names among the Parts of a Java Program

In This Chapter
- Hiding names from other classes
- Exposing names to other classes
- Tweaking your code to find the right middle ground

Speaking of private variables and methods (and I do speak about these things in this chapter) . . .

I’m eating lunch with some friends of mine at work. “They can read your e-mail,” says one fellow. Another chimes in, “They know every single Web site that you visit. They know what products you buy, what you eat for dinner, what you wear, what you think. They even know your deepest, darkest secrets. Why, I wouldn’t be surprised if they know when you’re going to die.”

A third voice enters the fray. “It’s getting to the point where you can’t blow your nose without someone taking a record of it. I visited a Web site a few weeks ago, and the page wished me a Happy Birthday. How did they know it was me, and how did they remember that it was my birthday?”

“Yeah,” says the first guy. “I have a tag on my car that lets me sail through toll booths. It senses that I’m going through and puts the charge on my credit card automatically. So every month, I get a list from the company showing where I’ve been and when I was there. I’m amazed it doesn’t say who I was visiting and what I did when I got there.”

I think quietly to myself. I think about saying, “That’s just a bunch of baloney. Personally, I’d be flattered if my employer, the government, or some big company thought so much of me that they tracked my every move. I have enough trouble getting people’s attention when I really want it. And most agencies that keep logs of all my purchasing and viewing habits can’t even spell my name right when they send me junk mail. ‘Hello, this is a courtesy call for Larry Burg. Is Mr. Burg at home?’ Spying on people is really boring. I can just see the headline on the front page of The Times: ‘Author of Java 2 For Dummies Wears His Undershirt Inside Out!’ Big deal!”
So I think for a few seconds, and then I say, “They’re out to get us. TV cameras! That’s the next big thing — TV cameras everywhere.”

**Access Modifiers**

If you’ve read this far into *Java 2 For Dummies, 2nd Edition* (or even if you’re browsing the bookstore shelves and have opened right to this chapter), you probably know one thing: Object-oriented programming is big on hiding details. Programmers who write one piece of code shouldn’t tinker with the details inside another programmer’s code. It’s not a matter of security and secrecy. It’s a matter of modularity. When you hide details, you keep the intricacies inside one piece of code from being twisted and broken by another piece of code. Your code comes in nice, discrete, manageable lumps. You keep complexity to a minimum. You make fewer mistakes. You save money. You help promote world peace.

Other chapters have plenty of examples of the use of private variables. When a variable is declared private, it’s hidden from all outside meddling. This hiding enhances modularity, minimizes complexity, and so on.

Elsewhere in the annals of *Java 2 For Dummies, 2nd Edition*, are examples of things that are declared public. Just like a public celebrity, a variable that’s declared public is left wide open. Plenty of people probably know what kind of toothpaste Elvis used, and any programmer can reference a public variable, even a variable that’s not named *Elvis*.

In Java, the words *public* and *private* are called *access modifiers*. No doubt you’ve seen variables and methods without access modifiers in their declarations. A method or variable of this kind is said to have default access. Many examples in this book use default access without making a big fuss about it. That’s okay in some chapters, but not in this chapter. In this chapter, I describe the nitty-gritty details about default access.

And you can find out about yet another access modifier that isn’t used in any example before this chapter. (At least, I don’t remember using it in any earlier examples.) It’s the *protected* access modifier. Yes, this chapter covers some of the slimy, grimy facts about protected access.

**Classes, Access, and Multipart Programs**

With this topic, you can become all tangled up in terminology, so you need to get some basics out of the way. (Most of the terminology that you need comes from Chapter 10, but it’s worth reviewing at the start of this chapter.) Here’s a fake piece of Java code:
Chapter 15: Sharing Names among the Parts of a Java Program

```java
class MyClass {
    int myVariable; // an instance variable
    // (a member)

    void myMethod() { // a method (another member)
        int myOtherVariable; // a method-local variable
        // (not a member)
    }
}
```

The comments on the right side of the code tell the whole story. Two kinds of variables exist here — instance variables and method-local variables. This chapter isn’t about method-local variables. It’s about methods and instance variables.

Believe me, carrying around the phrase “methods and instance variables” wherever you go isn’t easy. It’s much better to give these things one name and be done with it. That’s why both methods and instance variables are called *members* of a class.

**Members versus classes**

At this point, you make an important distinction. Think about Java’s `public` keyword. As you may already know from previous chapters, you can put `public` in front of a member. For example, you can write

```java
public static void main(String args[]) {
    // Your code goes here
}
```

or

```java
public amountInAccount = 50.22;
```

These uses of the `public` keyword come as no big surprise. What you may not already know is that you can put the `public` keyword in front of a class. For example, you can write

```java
public class Drawing {
    // Your code goes here
}
```

In Java, the `public` keyword has two slightly different meanings — one meaning for members, and another meaning for classes. Most of this chapter deals with the meaning of `public` (and of other such keywords) for members. The last part of this chapter (appropriately titled “Access Modifiers for Java Classes”) deals with the meaning for classes.
Access modifiers for members

Sure, this section is about members. But that doesn’t mean that you can ignore Java classes. Members or not, the Java class is still where all the action takes place. Each instance variable is declared in a particular class, belongs to that class, and is a member of that class. The same is true of methods. Each method is declared in a particular class, belongs to that class, and is a member of that class. Can you use a certain member name in a particular place in your code? To begin answering the question, you check to see whether that place is inside or outside of the member’s class:

✔ If the member is private, only code that’s inside the member’s class can refer directly to that member’s name.

```java
class SomeClass {
    private int myVariable = 10;
}

class SomeOtherClass {
    public static void main(String args[]) {
        SomeClass someObject = new SomeClass();

        //This doesn't work:
        System.out.println(someObject.myVariable);
    }
}
```

✔ If the member is public, any code can refer directly to that member’s name.

```java
class SomeClass {
    public int myVariable = 10;
}

class SomeOtherClass {
    public static void main(String args[]) {
        SomeClass someObject = new SomeClass();

        //This works:
        System.out.println(someObject.myVariable);
    }
}
```

Figures 15-1 through 15-3 illustrate the ideas in a slightly different way.
Figure 15-1: Several classes and their subclasses.

Figure 15-2: The range of code in which a public variable or method can be used (shaded).
Putting a drawing on a frame

To make this business about access modifiers clear, you need an example or two. In this chapter’s first example, almost everything is public. With public access, you don’t have to worry about who can use what.

The code for this first example comes in several parts. The first part, which is in Listing 15-1, displays an ArtFrame. On the face of the ArtFrame is a Drawing. If all the right pieces are in place, running the code of Listing 15-1 displays a window like the one in Figure 15-4.

Listing 15-1: Displaying a Frame

```java
import com.burdbrain.drawings.*;
import com.burdbrain.frames.ArtFrame;

class ShowFrame {
    public static void main(String args[]) {
        ArtFrame artFrame = new ArtFrame(new Drawing());
        artFrame.setSize(200, 100);
        artFrame.setVisible(true);
    }
}
```
The code in Listing 15-1 creates a new ArtFrame instance. You may suspect that ArtFrame is a subclass of a Java frame class, and that's certainly the case. Chapter 9 says that Java frames are, by default, invisible. So, in Listing 15-1, to make the ArtFrame instance visible, you call the setVisible method.

Now notice that Listing 15-1 starts with two import declarations. The first import declaration allows you to abbreviate any name from the com.burdbrain.drawings package. The second import declaration allows you to abbreviate the name ArtFrame.

For a review of import declarations, see Chapter 4.

The detective in you may be thinking, “He must have written more code (code that I don’t see here) and put that code in packages that he named com.burdbrain.drawings and com.burdbrain.frames.” And, indeed, you are correct. To make Listing 15-1 work, I need to create something called a Drawing, and I’m putting all my drawings in the com.burdbrain.drawings package. I also need an ArtFrame class, and I’m putting all such classes in my com.burdbrain.frames package.

So, really, what’s a Drawing? Well, if you’re so anxious to know, look at Listing 15-2.

Listing 15-2: The Drawing Class

```java
package com.burdbrain.drawings;
import java.awt.Graphics;

public class Drawing {
    public int x = 40, y = 40, width = 40, height = 40;

    public void paint(Graphics g) {
        g.drawOval(x, y, width, height);
    }
}
```

The code for the Drawing class is pretty slim. It contains a few int variables and a paint method. That’s all. Well, when I create my classes, I try to keep ’em lean. Anyway, here are some notes about my Drawing class:
At the top of the code is a package declaration. Lo and behold! I’ve made my Drawing class belong to a package — the com.burdbrain.drawings package. I didn’t pull this package name out of the air. The convention (handed down by the people at Sun Microsystems) says that you start a package name by reversing the parts of your domain name, so I reversed burdbrain.com. Then, you add one or more descriptive names, separated by dots. I added the name drawings because I intend to put all my drawing goodies in this package.

The Drawing class is public. A public class is vulnerable to intrusion from the outside. So in general, I avoid plastering the public keyword in front of any old class. But in Listing 15-2, I have to declare my Drawing class to be public. If I don’t, classes that aren’t in the com.burdbrain.drawings package can’t use the goodies in Listing 15-2. In particular, the line

```java
ArtFrame artFrame = new ArtFrame(new Drawing());
```

in Listing 15-1 is illegal unless the Drawing class is public.

For more information on public and nonpublic classes, see the section entitled “Access Modifiers for Java Classes,” later in this chapter.

The code has a paint method. This paint method uses a standard Java trick for making things appear on-screen. The parameter g in Listing 15-2 is called a graphics buffer. To make things appear, all you do is draw on this graphics buffer, and the buffer is eventually rendered on the computer screen.

Here’s a little more detail: In Listing 15-2, the paint method takes a g parameter. This g parameter refers to an instance of the java.awt.Graphics class. Because a Graphics instance is a buffer, the things that you put onto this buffer are eventually displayed on the screen. Like all instances of the java.awt.Graphics class, this buffer has several drawing methods — one of them being drawOval. When you call drawOval, you specify a starting position (x pixels from the left edge of the frame and y pixels from the top of the frame). You also specify an oval size by putting numbers of pixels in the width and height parameters. Calling the drawOval method puts a little round thing into the Graphics buffer. That Graphics buffer, round thing and all, is displayed on-screen.

**Directory structure**

The code in Listing 15-2 belongs to the com.burdbrain.drawings package. When you put a class into a package, you have to create a directory structure that mirrors the name of the package. If you use JCreator, building this directory structure is easy. (See the “Using Java packages in JCreator” section, later in this chapter.) In fact, if you load JCreator from this book’s CD-ROM, the directory structures for all the book’s examples are installed automatically.
Even if you don’t use JCreator, understanding this directory business is handy. To house code that’s in the `com.burdbrain.drawings` package, you have to have three directories: a `com` directory, a subdirectory of `com` named `burdbrain`, and a subdirectory of `burdbrain` named `drawings`. The overall directory structure is shown in Figure 15-5.

If you don’t have your code in appropriate directories, you get a repulsive and disgusting `NoClassDefFoundError`. Believe me, this error is never fun to get. When you see this error, you don’t have any clues to help you figure out where the missing class is or where the compiler expects to find it. If you stay calm, you can figure out all this stuff on your own. If you panic, you’ll be poking around for hours. As a seasoned Java programmer, I can remember plenty of scraped knuckles that came from this heinous `NoClassDefFoundError`.

**Using Java packages in JCreator**

When you become a seasoned Java programmer, you’ll put your own Java programs into your own packages. If you use JCreator, this process is easy. Imagine that you’re writing a program as part of your new `com.myhomedomain.stuff` package.
package com.myhomedomain.stuff;

class MyCode {
    public static void main(String args[]) {
        System.out.println("I'm in a package.");
    }
}

This is how you make a new MyCode.java file in JCreator:

1. **Follow Steps 1 through 7 in the last section of Chapter 3.**
   In these steps, you start JCreator, open a workspace, and create a project. The steps are the same whether you work with packages or not.

2. **Follow Steps 8 and 9 in the last section of Chapter 3.**
   In these steps, you begin creating a new Java class. A Class Wizard dialog box is showing on your screen. You can see the wizard's Class Settings page. (See Figure 15-6.)

3. **In the dialog box's Package text box, type the name of the package that will be housing your code.** (See Figure 15-6.)
   As you type a dotted package name (like `com.myhomedomain.stuff`), JCreator automatically creates the appropriate directory structure (like `com\myhomedomain\stuff`). To see this for yourself, check the Location field in Figure 15-6.

4. **Click Finish, and then type your Java code.**
   That's all you have to do.
Looking for files in all the right places

You try to compile the program in Listing 15-1. The Java compiler pokes through the code and stumbles upon some missing pieces. First there’s this thing called an ArtFrame. Then you have this Drawing business. Listing 15-1 defines a class named ShowFrame, not ArtFrame or Drawing. So where does the compiler go for information about the ArtFrame and Drawing classes?

If you stop to think about it, the problem can be daunting. Should the compiler go searching all over your hard drive for files named ArtFrame.java or Drawing.class? How large is your new hard drive? 120GB? 240GB? 6,000,000GB? And what about references to files on network drives? The search space is potentially unlimited. What if the compiler eventually resolves all these issues? Then you try to run your code and the Java Virtual Machine (JVM) starts searching all over again. (For info on the Java Virtual Machine, see Chapter 2.)

To tame this problem, Java defines something called a CLASSPATH. The CLASSPATH is a list of places where the compiler and the JVM look for code. JCreator buries this CLASSPATH deep inside its program options. That’s why you don’t have to think about the CLASSPATH when you run this book’s examples. (In JCreator, the settings for certain JDK tools include the text -classpath "$[ClassPath]". Take my word for it — this fixes the problem for most small programming projects.)

The non-JCreator world has several ways to set a CLASSPATH. Some programmers create a new CLASSPATH each time they run a Java program. Others create a system-wide CLASSPATH variable. (If you’re familiar with the PATH variable on Windows and UNIX computers, you may already know how this stuff works.) One way or another, the compiler and the JVM need a list of places to look for code. Without such a list, these Java tools don’t look anywhere. They don’t find classes like ArtFrame or Drawing. You get a cannot find symbol message or a NoClassDefFoundError message, and you’re very unhappy.

If you installed JCreator from this book’s CD-ROM, you don’t have to think about all this. If not, or if you do fancy things with Java packages, a healthy understanding of the CLASSPATH may be useful to you. If so, I recommend a visit to this book’s Web site. At the Web site you can find out more about the intricacies of Java’s CLASSPATH.

Making a frame

This chapter’s first three listings develop one multipart example. This section has the last of three pieces in that example. This last piece isn’t crucial for the understanding of access modifiers, which is the main topic of this chapter. So, if you want to skip past the explanation of Listing 15-3, you can skip it without losing the chapter’s thread. On the other hand, if you want to know more about the Java Swing classes, read on.
Listing 15-3: The ArtFrame Class

```java
package com.burdbrain.frames;

import com.burdbrain.drawings.*;
import javax.swing.JFrame;
import java.awt.Graphics;

public class ArtFrame extends JFrame {
    Drawing drawing;

    public ArtFrame(Drawing drawing) {
        this.drawing = drawing;
        setTitle("Abstract Art");
        setDefaultCloseOperation(EXIT_ON_CLOSE);
    }

    public void paint(Graphics g) {
        drawing.paint(g);
    }
}
```

Listing 15-3 has all the gadgetry that you need for putting a drawing on a Java frame. The code uses several names from the Java API (Application Programming Interface). I explain most of these names in Chapters 9 and 10.

The only new name in Listing 15-3 is the word `paint`. The `paint` method in Listing 15-3 defers to another `paint` method — the `paint` method belonging to a `Drawing` object. The `ArtFrame` object creates a floating window on your computer screen. What’s drawn in that floating window depends on whatever `Drawing` object was passed to the `ArtFrame` constructor.

If you trace the flow of Listings 15-1 through 15-3, you may notice something peculiar. The `paint` method in Listing 15-3 never seems to be called. Well, for many of Java’s window-making components, you just declare a `paint` method and let the method sit there quietly in the code. When the program runs, the computer calls the `paint` method automatically.

That’s what happens with `javax.swing.JFrame` objects. In Listing 15-3, the frame’s `paint` method is called from behind the scenes. Then, the frame’s `paint` method calls the `Drawing` object’s `paint` method, which in turn, draws an oval on the frame. That’s how you get the stuff you see in Figure 15-4.

**Sneaking Away from the Original Code**

Your preferred software vendor, Burd Brain Consulting, has sold you two files — `Drawing.class` and `ArtFrame.class`. As a customer, you can’t see the code inside the files `Drawing.java` and `ArtFrame.java`. So, you have to live with whatever happens to be inside these two files. (If only you’d
purchased a copy of *Java 2 For Dummies*, 2nd Edition, which has the code for these files in Listings 15-2 and 15-3! Anyway, you want to tweak the way the oval looks in Figure 15-4 so that it’s a bit wider. To do this, you create a subclass of the `Drawing` class — `DrawingWide` — and put it in Listing 15-4.

### Listing 15-4: A Subclass of the Drawing Class

```java
import com.burdbrain.drawings.*;
import java.awt.Graphics;

public class DrawingWide extends Drawing {
    int width = 100, height = 30;
    
    public void paint(Graphics g) {
        g.drawOval(x, y, width, height);
    }
}
```

To make use of the code in Listing 15-4, you remember to change one of the lines in Listing 15-1. You change the line to

```java
ArtFrame artFrame = new ArtFrame(new DrawingWide());
```

Listing 15-4 defines a subclass of the original `Drawing` class. In that subclass, you override the original class’s width and height variables and the original class’s `paint` method. The frame that you get is shown in Figure 15-7.

In passing, you may notice that the code in Listing 15-4 doesn’t start with a package declaration. This means that your whole collection of files comes from the following three packages:

- **The `com.burdbrain.drawings` package.** The original `Drawing` class from Listing 15-2 is in this package.
- **The `com.burdbrain.frames` package.** The `ArtFrame` class from Listing 15-3 is in this package.
- **An ever-present, unnamed package.** In Java, when you don’t start a file with a package declaration, all the code in that file goes into one big, unnamed package. Listings 15-1 and 15-4 are in the same unnamed package. In fact, most of the listings from the first 12 chapters of this book are in Java’s unnamed package.
At this point, your project has two drawing classes — the original Drawing class and your new DrawingWide class. Similar as these classes may be, they live in two separate packages. That’s not surprising. The Drawing class, developed by your friends at Burd Brain Consulting, lives in a package whose name starts with com.burdbrain. But you developed DrawingWide on your own, so you shouldn’t put it in a com.burdbrain package. The most sensible thing to do is to put it in one of your own packages, such as com.myhomedomain.drawings, but putting your class in the unnamed package will do for now.

One way or another, your DrawingWide subclass compiles and runs as planned. You go home, beaming with the confidence of having written useful, working code.

**Default access**

If you’re reading these paragraphs in order, you know that the last example ends very happily. The code in Listing 15-4 runs like a charm. Everyone, including my wonderful editor, Paul Levesque, is happy.

But, wait! Do you ever wonder what life would be like if you hadn’t chosen that particular career, dated that certain someone, or read that certain For Dummies book? In this section, I roll back the clock a bit to show you what would have happened if one word had been omitted from the code in Listing 15-2.

Dealing with different versions of a program can give you vertigo, so I start this discussion by describing what you’ve got. First, you have a Drawing class. In this class, the variables aren’t declared to be public and have the default access. The Drawing class lives in the com.burdbrain.drawings package. (See Listing 15-5.)

**Listing 15-5: Variables with Default Access**

```java
package com.burdbrain.drawings;

import java.awt.Graphics;

public class Drawing {
    int x = 40, y = 40, width = 40, height = 40;

    public void paint(Graphics g) {
        g.drawOval(x, y, width, height);
    }
}
```
Next, you have a `DrawingWide` subclass (copied, for your convenience, in Listing 15-6). The `DrawingWide` class is in Java’s unnamed package.

### Listing 15-6: A Failed Attempt to Create a Subclass
```java
import com.burdbrain.drawings.*;
import java.awt.Graphics;

public class DrawingWide extends Drawing {
    int width = 100, height = 30;

    public void paint(Graphics g) {
        g.drawOval(x, y, width, height);
    }
}
```

The trouble is that the whole thing falls apart at the seams. The code in Listing 15-6 doesn’t compile. Instead, you get the following error messages:

```
x is not public in com.burdbrain.drawings.Drawing;
cannot be accessed from outside package
y is not public in com.burdbrain.drawings.Drawing;
cannot be accessed from outside package
```

The code doesn’t compile, because an instance variable that has default access can’t be directly referenced outside its package — not even by a subclass of the class containing the variable. The same holds true for any methods that have default access.

A class’s instance variables and methods are called members of the class. The rules for access, default and otherwise, apply to all members of classes.

The access rules that I describe in this chapter don’t apply to method-local variables. A method-local variable can be accessed only within its own method.

For the rundown on method-local variables, see Chapter 10.

In Java, the default access for a member of a class is package-wide access. A member declared without the word `public, private, or protected` in front of it is accessible in the package in which its class resides. Figures 15-8 and 15-9 illustrate the point.
class1 | classA | classX
---|---|---
class2 | classB | classY
  extends class1 |  extends classA |  extends classX
class3 | classC | classZ
  extends class2 |  extends classB |  extends classY

Legend:
- A package
- Another package
- Yet another package

**Figure 15-8:**
Packages cut across subclass hierarchies.

**Figure 15-9:**
The range of code in which a default variable or method can be used (shaded).
The names of packages, with all their dots and subparts, can be slightly misleading. For instance, when you write a program that responds to button clicks, you normally import classes from two separate packages. On one line, you may have
import java.awt.;
On another line, you may have
import java.awt.event.; Importing all classes from the java.awt package doesn't automatically import classes from the java.awt.event package.

**Crawling back into the package**

I love getting things in the mail. At worst, it’s junk mail that I can throw right into the trash. At best, it’s something I can use, a new toy, or something somebody sent especially for me.

Well, today is my lucky day. Somebody from Burd Brain Consulting sent a subclass of the Drawing class. It’s essentially the same as the code in Listing 15-6. The only difference is that this new DrawingWideBB class lives inside the com.burdbrain.drawings package. The code is shown in Listing 15-7. To run this code, I have to modify Listing 15-1 with the line

ArtFrame artFrame = new ArtFrame(new DrawingWideBB());

**Listing 15-7: Yes, Virginia, This Is a Subclass**

```java
package com.burdbrain.drawings;
import java.awt.Graphics;

public class DrawingWideBB extends Drawing {
    int width = 100, height = 30;

    public void paint(Graphics g) {
        g.drawOval(x, y, width, height);
    }
}
```

When you run Listing 15-7 alongside the Drawing class in Listing 15-5, everything works just fine. The reason? It’s because Drawing and DrawingWideBB are in the same package. Look back at Figure 15-9 and notice the shaded region that spans across an entire package. Being in the same package, the code in the DrawingWideBB class has every right to use the x and y variables, which are defined with default access in the Drawing class.
When I was first getting to know Java, I thought the word *protected* meant *nice and secure*, or something like that. “Wow, that variable is protected. It must be hard to get at.” Well, this notion turned out to be wrong. In Java, a member that’s protected is less hidden, less secure, and easier to use than one that has default access. The concept is rather strange.

Think of protected access this way. You start with an instance variable that has default access (a variable without the word *public, private, or protected* in its declaration). That variable can be accessed only inside the package in which it lives. Now add the word *protected* to the front of the variable’s declaration. Suddenly, classes outside that variable’s package have some access to the variable. A subclass (of the class in which the variable is declared) can now reference the variable. You can also reference the variable from a sub-subclass, a sub-sub-subclass, and so on. Any descendent class will do. For an example, see Listings 15-8 and 15-9.

### Listing 15-8: Protected Variables
```java
package com.burdbrain.drawings;
import java.awt.Graphics;

public class Drawing {
    protected int x = 40, y = 40, width = 40, height = 40;

    public void paint(Graphics g) {
        g.drawOval(x, y, width, height);
    }
}
```

### Listing 15-9: The Subclass from the Blue Lagoon, Part II
```java
import com.burdbrain.drawings.*;
import java.awt.Graphics;

public class DrawingWide extends Drawing {
    int width = 100, height = 30;

    public void paint(Graphics g) {
        g.drawOval(x, y, width, height);
    }
}
```

Listing 15-8 defines the `Drawing` class. Listing 15-9 defines `DrawingWide`, which is a subclass of the `Drawing` class.
In the `Drawing` class, the `x`, `y`, `width`, and `height` variables are protected. The `DrawingWide` class has its own `width` and `height` variables, but `DrawingWide` references the `x` and `y` variables that are defined in the parent `Drawing` class. That’s okay even though `DrawingWide` isn’t in the same package as its parent `Drawing` class. (The `Drawing` class is in the `com.burdbrain.drawings` package; the `DrawingWide` class is in Java’s great, unnamed package.) It’s okay because the `x` and `y` variables are protected in the `Drawing` class.

Compare Figures 15-9 and 15-10. Notice the extra bit of shading in Figure 15-10. A subclass can access a protected member of a class, even if that subclass belongs to some other package.

Do you work with a team of programmers? Do people from outside your team use their own team’s package names? If so, when they use your code, they may make subclasses of the classes that you’ve defined. This is where protected access comes in handy. Use protected access when you want people from outside your team to make direct references to your code’s variables or methods.

**Figure 15-10:** The range of code in which a protected variable or method can be used (shaded).
Putting non-subclasses in the same package

Those people from Burd Brain Consulting are sending you one piece of software after another. This time, they’ve sent an alternative to the ShowFrame class — the class in Listing 15-1. This new ShowFrameWideBB class displays a wider oval (how exciting!), but it does this without creating a subclass of the old Drawing class. Instead, the new ShowFrameWideBB code creates a Drawing instance and then changes the value of the instance’s width and height variables. The code is shown in Listing 15-10.

Listing 15-10: Drawing a Wider Oval

```java
package com.burdbrain.drawings;

import com.burdbrain.frames.ArtFrame;

class ShowFrameWideBB {
    public static void main(String args[]) {
        Drawing drawing = new Drawing();
        drawing.width = 100;
        drawing.height = 30;

        ArtFrame artFrame = new ArtFrame(drawing);
        artFrame.setSize(200, 100);
        artFrame.setVisible(true);
    }
}
```

So, here’s the story. This ShowFrameWideBB class in Listing 15-10 is in the same package as the Drawing class (the com.burdbrain.drawings package). But ShowFrameWideBB isn’t a subclass of the Drawing class.

Now imagine compiling ShowFrameWideBB with the Drawing class that’s shown in Listing 15-8 — the class with all those protected variables. What happens? Well, everything goes smoothly, because a protected member is available in two (somewhat unrelated) places. Look again at Figure 15-10. A protected member is available to subclasses outside the package, but the member is also available to code (subclasses or not) within the member’s package.

Listing 15-10 has a main method, which is inside a class, which is in turn inside the com.burdbrain.drawings package. With a development environment like JCreator, you don’t think twice about running a main method that’s in a named package. But if you run programs from the command line (or if your development environment doesn’t find main methods on its own), you
may need to wield names like `com.burdbrain.drawings.ShowFrameWideBB` (the fully qualified name of the package in Listing 15-10). For tips on running ShowFrameWideBB in environments other than JCreator, visit this book’s Web site.

The real story about protected access is one step more complicated than the story that I describe in this section. The Java Language Specification mentions a hair-splitting point about code being responsible for an object’s implementation. When you’re first figuring out how to program in Java, don’t worry about this point. Wait until you’ve written many Java programs. Then, when you stumble upon a variable has protected access error message, you can start worrying. Better yet, skip the worrying and take a careful look at the protected access section in the Java Language Specification.

For info about the Java Language Specification, visit Chapter 3.

### Access Modifiers for Java Classes

Maybe the things that you read about access modifiers for members make you a tad dizzy. After all, member access in Java is a very complicated subject with lots of plot twists and cliffhangers. Well, the dizziness is over. Compared with the saga for variables and methods, the access story for classes is rather simple.

A class can be either public or nonpublic. If you see something like

```java
public class Drawing
```

then you’re looking at the declaration of a public class. But, if you see plain old

```java
class ShowFrame
```

then the class that’s being declared isn’t public.

### Public classes

If a class is public, you can refer to the class from anywhere in your code. Of course, some restrictions apply. You must obey all the rules in this chapter’s “Directory structure” section. If you’re creating code on your own, you have to follow the steps in this chapter’s “Using Java packages in JCreator” section.

You must also refer to a packaged class properly. For example, in Listing 15-1, you can write
import com.burdbrain.drawings.*;
import com.burdbrain.frames.ArtFrame;
...
ArtFrame artFrame = new ArtFrame(new Drawing());

or you can do without the import declarations and write

com.burdbrain.frames.ArtFrame artFrame =
    new com.burdbrain.frames.ArtFrame
    (new com.burdbrain.drawings.Drawing());

One way or another, your code must acknowledge the fact that the ArtFrame and Drawing classes are in named packages.

**Nonpublic classes**

If a class isn’t public, you can refer to the class only from code within the class’s package.

I tried it. First, I went back to Listing 15-2 and deleted the word `public`. I turned `public class Drawing` into `plain old class Drawing, like this:

```java
package com.burdbrain.drawings;
import java.awt.Graphics;

class Drawing {
    public int x = 40, y = 40, width = 40, height = 40;
    public void paint(Graphics g) {
        g.drawOval(x, y, width, height);
    }
}
```

Then I compiled the code in Listing 15-7. Everything was peachy because Listing 15-7 starts with the following lines:

```java
package com.burdbrain.drawings;

public class DrawingWideBB extends Drawing
```

Because both pieces of code are in the same `com.burdbrain.drawings` package, access from `DrawingWideBB back to the nonpublic Drawing class was no problem at all.
But then I tried to compile the code in Listing 15-3. The code in Listing 15-3 begins with

```
package com.burdbrain.frames;
```

That code isn't in the `com.burdbrain.drawings` package. So when the computer reached the line

```
Drawing drawing;
```

from Listing 15-3, the computer went *poof!* To be more precise, the computer displayed this message:

```
com.burdbrain.drawings.Drawing is not public in com.burdbrain.drawings;
cannot be accessed from outside package
```

Well, I guess I got what was coming to me.

Things are never as simple as they seem. The rules that I describe in this section apply to almost every class in this book. But Java’s inner classes (which I introduce in Chapter 9) follow a different set of rules. Fortunately, a typical novice programmer has little contact with inner classes. The only inner classes in this book are disguised as `enum` types. So for now, you can live very happily with the rules that I describe in this section.
Chapter 16

Responding to Keystrokes and Mouse Clicks

In This Chapter

- Creating code to handle mouse clicks (and other such events)
- Writing and using a Java interface

In the late 1980s, I bought my first mouse. I paid $100 and, because I didn’t really need a mouse, I checked with my wife before buying it. (At the time, my computer ran a hybrid text/windowed environment. Anything that I could do with a mouse, I could just as easily do with the Alt key.)

Now it’s the 21st century. The last ten mice that I got were free. Ordinary ones just fall into my lap somehow. A few exotic mice were on sale at the local computer superstore. One cost $10 and came with a $10 rebate.

As I write this chapter, I’m using the most recent addition to my collection — an official *For Dummies* mouse. This yellow and white beauty has a little compartment filled with water. Instead of a snowy Atlantic City scene, the water surrounds a tiny Dummies Man charm. It’s so cute. It was a present from the folks at Wiley Publishing.

Go On... Click That Button

In previous chapters, I create windows that don’t do much. A typical window displays some information but doesn’t have any interactive elements. Well, the time has come to change all that. This chapter’s first example is a window with a button on it. When the user clicks the button, darn it, something happens. The code is shown in Listing 16-1.
Listing 16-1:  A Guessing Game

import java.util.Random;
import javax.swing.*;
import java.awt.FlowLayout;
import java.awt.event.ActionEvent;
import java.awt.event.ActionListener;

class GameFrame extends JFrame implements ActionListener {
    int randomNumber = new Random().nextInt(10) + 1;
    int numGuesses = 0;

    JTextField textField = new JTextField(5);
    JButton button = new JButton("Guess");
    JLabel label = new JLabel(numGuesses + " guesses");

    public GameFrame() {
        setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
        setLayout(new FlowLayout());
        add(textField);
        add(button);
        add(label);
        button.addActionListener(this);
        pack();
        setVisible(true);
    }

    public void actionPerformed(ActionEvent e) {
        String textFieldText = textField.getText();

        if (Integer.parseInt(textFieldText) == randomNumber) {
            button.setEnabled(false);
            textField.setText(textField.getText() + " Yes!");
            textField.setEnabled(false);
        } else {
            textField.setText("");
        }

        numGuesses++;
        String guessWord =
            (numGuesses == 1) ? " guess" : " guesses";
        label.setText(numGuesses + guessWord);
    }
}

Listing 16-2:  Starting the Guessing Game

class ShowGameFrame {
    public static void main(String args[]) {
        new GameFrame();
    }
}
Some snapshots from a run of this section’s code are shown in Figures 16-1 and 16-2. In a window, the user plays a guessing game. Behind the scenes, the program chooses a secret number (a number from 1 to 10). Then the program displays a text field and a button. The user types a number in the text field and clicks the button. One of two things happens next:

- If the number that the user types isn’t the same as the secret number, the computer posts the number of guesses made so far. The user gets to make another guess.
- If the number that the user types is the same as the secret number, the text field displays Yes!. Meanwhile, the game is over, so both the text field and the button become disabled. Both components have that gray, washed-out look, and neither component responds to keystrokes or mouse clicks.

In Listing 16-1, the code to create the frame, the button, and the text field isn’t earth-shattering. I did similar things in Chapters 9 and 10. The JTextField class is new in this chapter, but a text field isn’t much different from a button or a label. Like so many other components, the JTextField class is defined in the javax.swing package. When you create a new JTextField instance, you have the option of specifying a number of columns. In Listing 16-1, I create a text field that’s five columns wide.

Listing 16-1 uses a fancy operator to decide between the singular guess and the plural guesses. If you’re not familiar with this use of the question mark and colon, see Chapter 11.

**Events and event handling**

The big news in Listing 16-1, shown in the previous section, is the handling of the user’s button click. When you’re working in a graphical user interface (GUI), anything the user does (like pressing a key, moving the mouse, clicking...
the mouse, or whatever) is called an event. The code that responds to the user’s press, movement, or click is called event-handling code.

Listing 16-1 deals with the button-click event with three parts of its code:

- The top of the GameFrame class declaration says that this class implements ActionListener.
- The constructor for the GameFrame class adds this to the button’s list of action listeners.
- The code for the GameFrame class has an actionPerformed method.

Taken together, all three of these tricks make the GameFrame class handle button clicks. To understand how it works, you have to know about something called an interface, which I discuss in the following section.

The Java interface

You may have noticed that, in Java, you never get a class to extend more than one parent class. In other words, you never say

```java
class DontDoThis extends FirstClass, SecondClass, ThirdClass
```

A class can have only one parent class, and that’s fine when you want your new class to be like a frame. But what if you want your new class to be like a frame and a button-click-listening thing? Can your new class be like both things?

Yes, it can be. Java has this thing called an interface. An interface is like a class, but it’s different. (So, what else is new? A cow is like a planet, but it’s quite a bit different. Cows moo; planets hang in space.) Anyway, when you hear the word interface, you can start by thinking of a class. Then, in your head, note the following things:

- A class can extend only one parent class, but a class can implement more than one interface.

  For instance, if you want GameFrame to listen for keystrokes as well as button clicks, you can say

  ```java
class GameFrame extends JFrame
      implements ActionListener, ItemListener
  ```

- An interface’s methods have no bodies of their own.
Here’s a copy of the API code for the `ActionListener` interface:

```java
package java.awt.event;
import java.util.EventListener;
public interface ActionListener extends EventListener {
    public void actionPerformed(ActionEvent e);
}
```

I’ve removed the code’s comments, but I’ve avoided messing with the API code in any significant ways. In this code, the `actionPerformed` method has no body — no curly braces and no statements to execute. In place of a body, there’s just a semicolon.

A method with no body, like the method defined in the `ActionListener` interface, is called an *abstract* method.

> **When you implement an interface, you provide bodies for all the interface’s methods.**

That’s why an `actionPerformed` method is in Listing 16-1. By announcing that it will implement the `ActionListener` interface, the code in Listing 16-1 agrees that it will give meaning to the interface’s `actionPerformed` method. In this situation, *giving meaning* means declaring an `actionPerformed` method with curly braces, a body, and maybe some statements to execute.

When you announce that you’re going to implement an interface, the Java compiler takes this announcement seriously. Later on in the code, if you fail to give meaning to any of the interface’s methods, the compiler yells at you.

If you’re really lazy, you can quickly find out what methods need to be declared in your interface-implementing code. Try to compile the code, and the compiler lists all the methods that you should have declared but didn’t.

**Threads of execution**

Here’s a well-kept secret: Java programs are *multithreaded*, which means that several things are going on at once whenever you run a Java program. Sure, the computer is executing the code that you’ve written, but it’s executing other code as well (code that you didn’t write and don’t see). All this code is being executed at the same time. While the computer executes your main method’s statements, one after another, the computer takes time out, sneaks away briefly, and executes statements from some other, unseen methods. For most simple Java programs, these other methods are methods that are defined as part of the Java Virtual Machine (JVM).
For instance, Java has an event-handling thread. While your code runs, the event-handling thread’s code runs in the background. The event-handling thread’s code listens for mouse clicks and takes appropriate action whenever a user clicks the mouse. Figure 16-3 illustrates how this works.

When the user clicks the button, the event-handling thread says, “Okay, the button was clicked. So, what should I do about that?” And the answer is, “Call some actionPerformed methods.” It’s as if the event-handling thread had code that looks like this:

```java
if (buttonJustGotClicked()) {
    object1.actionPerformed(infoAboutTheClick);
    object2.actionPerformed(infoAboutTheClick);
    object3.actionPerformed(infoAboutTheClick);
}
```

Of course, behind every answer is yet another question. In this situation, the follow-up question is, “Where does the event-handling thread find actionPerformed methods to call?” And there’s another question: “What if you don’t want the event-handling thread to call certain actionPerformed methods that are lurking in your code?”

Well, that’s why you call the addActionListener method. In Listing 16-1, the call

```java
button.addActionListener(this);
```

 tells the event-handling thread, “Put this code’s actionPerformed method on your list of methods to be called. Call this code’s actionPerformed method whenever the button is clicked.”

So, that’s how it works. To have the computer call an actionPerformed method, you register the method with Java’s event-handling thread. You do this registration by calling addActionListener. The addActionListener
The keyword **this**

In Chapters 9 and 10, the keyword **this** gives you access to instance variables from the code inside a method. So, what does the **this** keyword really mean? Well, compare it with the English phrase “state your name.”

\[
I, (\text{state your name}), \text{do solemnly swear, to uphold the constitution of the Philadelphia Central High School Photography Society. . . .}
\]

The phrase “state your name” is a placeholder. It’s a space in which each person puts his or her own name.

\[
I, \text{Bob, do solemnly swear. . . .}
\]

\[
I, \text{Fred, do solemnly swear. . . .}
\]

Think of the pledge (“I . . . do solemnly swear . . .”) as a piece of code in a Java class. In that piece of code is the placeholder phrase, “state your name.” Whenever an instance of the class (a person) executes the code (that is, takes the pledge), the instance fills in its own name in place of the phrase “state your name.”

The **this** keyword works the same way. It is sitting inside the code that defines the **GameFrame** class. Whenever an instance of **GameFrame** is constructed, the instance calls `addActionListener(this)`. In that call, the **this** keyword stands for the instance itself.

```
button.addActionListener(thisGameFrameInstance);
```

By calling `button.addActionListener(this)`, the **GameFrame** instance is saying, “Add my `actionPerformed` method to the list of methods that are called whenever the button is clicked.” And indeed, the **GameFrame** instance has an `actionPerformed` method. The **GameFrame** has to have an `actionPerformed` method, because the **GameFrame** class implements the `ActionListener` interface. It’s funny how that all fits together.

**Inside the **actionPerformed** method**

The `actionPerformed` method in Listing 16-1 uses a bunch of tricks from the Java API. Here’s a brief list of tricks:
Every instance of JTextField (and of JLabel) has methods — getText and setText. Calling getText fetches whatever string of characters is in the component. Calling setText changes the characters that are in the component. In Listing 16-1, judicious use of getText and setText pulls a number out of the text field and replaces the number with either nothing (the empty string ""), or the number, followed by the word Yes!

Every component in the javax.swing package (JTextField, JButton, or whatever) has a setEnabled method. When you call setEnabled(false), the component gets that limp, gray, washed-out look and can no longer receive button clicks or keystrokes.

You can perform a test to make sure that the object referred to by the button variable is really the thing that was clicked. Just write if (e.getSource() == button). If your code has two buttons, button1 and button2, you can test to find out which button was clicked. You can write if (e.getSource() == button1) and if (e.getSource() == button2).

### Responding to Things Other Than Button Clicks

When you know how to respond to one kind of event, responding to other kinds of events is easy. Listings 16-3 and 16-4 display a window that shows amounts as U.S. or U.K. currencies. The code in these listings responds to many kinds of events. Figures 16-4, 16-5, and 16-6 show some pictures of the code in action.

### Listing 16-3: Displaying the Local Currency

```java
import javax.swing.*;
import javax.swing.event.DocumentListener;
import javax.swing.event.DocumentEvent;
import java.awt.FlowLayout;
import java.awt.Color;
import java.awt.event.*;
import java.text.NumberFormat;
import java.util.Locale;

class MoneyFrame extends JFrame implements DocumentListener, ItemListener, MouseListener {
    JTextField textField = new JTextField(5);
    JComboBox combo = new JComboBox();
    JLabel label = new JLabel(" ");
```
NumberFormat currencyUS =
    NumberFormat.getCurrencyInstance();
NumberFormat currencyUK =
    NumberFormat.getCurrencyInstance(Locale.UK);

public MoneyFrame() {
    setLayout(new FlowLayout());
    add(textField);
    combo.addItem("US");
    combo.addItem("UK");
    add(combo);
    add(label);
    textField.getDocument().addDocumentListener(this);
    combo.addItemListener(this);
    label.addMouseListener(this);
    setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
    setSize(300, 100);
    setVisible(true);
}

void setTextOnLabel() {
    String amountString = "";
    try {
        double amount =
            Double.parseDouble(textField.getText());
        if (combo.getSelectedItem().equals("US"))
            amountString = currencyUS.format(amount);
        if (combo.getSelectedItem().equals("UK"))
            amountString = currencyUK.format(amount);
    } catch (NumberFormatException e) {
    }
    label.setText(amountString);
}

public void insertUpdate(DocumentEvent d) {
    setTextOnLabel();
}

public void removeUpdate(DocumentEvent d) {
    setTextOnLabel();
}
Listing 16-3 (continued)

```java
public void changedUpdate(DocumentEvent d) {
}

public void itemStateChanged(ItemEvent i) {
    setTextOnLabel();
}

public void mouseEntered(MouseEvent m) {
    label.setForeground(Color.red);
}

public void mouseExited(MouseEvent m) {
    label.setForeground(Color.black);
}

public void mouseClicked(MouseEvent m) {
}

public void mousePressed(MouseEvent m) {
}

public void mouseReleased(MouseEvent m) {
}
```

Listing 16-4: Calling the Code in Listing 16-3

```java
class ShowMoneyFrame {
    public static void main(String args[]) {
        new MoneyFrame();
    }
}
```

Figure 16-4: U.S. currency.

Figure 16-5: Using the combo box.
Okay, so Listing 16-3 is a little long. Even so, the outline of the code in Listing 16-3 isn’t too bad. Here’s what the outline looks like:

```java
class MoneyFrame extends JFrame implements DocumentListener, ItemListener,MouseListener {

    variable declarations

    constructor for the MoneyFrame class

    declaration of a method named setTextOnLabel

    all the methods that are required because the class implements three interfaces
}
```

The constructor in Listing 16-3 adds the following three components to the new MoneyFrame window:

- **A text field**: In Figure 16-4, the user types 22 in the text field.
- **A combo box**: In Figure 16-4, the combo box displays US. In Figure 16-5, the user selects an item in the box. In Figure 16-6, the selected item is UK.
- **A label**: In Figure 16-4, the label displays $22.00.

The MoneyFrame implements three interfaces — the DocumentListener, ItemListener, and MouseListener interfaces. Because it implements three interfaces, the code can listen for three different kinds of events. I discuss the interfaces and events in the following list:

- **DocumentListener**: A class that implements the DocumentListener interface must have three methods named insertUpdate, removeUpdate, and changedUpdate. When you type a digit in a text field, the event-handling thread calls insertUpdate. Erasing a digit from the field gets the event-handling thread to call removeUpdate.
  
  In Listing 16-3, the insertUpdate and removeUpdate methods call setTextOnLabel. My setTextOnLabel method checks to see what’s currently selected in the combo box. If the user selects the US option, the setTextOnLabel method formats dollars. If the user selects the UK option, the setTextOnLabel method formats pounds.

![Figure 16-6: U.K. currency.](image-url)
By the way, if you’re thinking in terms of real currency conversion, forget about it. This program just changes back and forth between a dollar sign and a pound sign. Sure, there are easier ways to accomplish this task, but you’ve got bigger Java fish to fry.

- **ItemListener**: A class that implements the `ItemListener` interface must have an `itemStateChanged` method. When you select an item in a combo box, the event-handling thread calls `itemStateChanged`.

  In Listing 16-3, when the user selects US or UK in the combo box, the event-handling thread calls the `itemStateChanged` method. In turn, the `itemStateChanged` method calls `setTextOnLabel`, and so on.

- **MouseListener**: A class that implements the `MouseListener` interface must have `mouseEntered`, `mouseExited`, `mouseClicked`, `mousePressed`, and `mouseReleased` methods. Implementing `MouseListener` is different from implementing `ActionListener`. When you implement `ActionListener`, as in Listing 16-1, the event-handling thread responds only to mouse clicks. But with `MouseListener`, the thread responds to the user pressing the mouse, releasing the mouse, and more.

  In Listing 16-3, the `mouseEntered` and `mouseExited` methods are called whenever you move over or away from the label. How do you know that the label is involved? Just look at the code in the `MoneyFrame` constructor. The `label` variable’s `addMouseListener` method is the one that’s called.

  Look at the `mouseEntered` and `mouseExited` methods in Listing 16-3. When `mouseEntered` or `mouseExited` is called, the computer forges ahead and calls `setForeground`. This `setForeground` method changes the color of the label’s text. (Maybe you can see the red text in Figure 16-6; maybe you can’t. I don’t know whether colors appear in this CD-ROM chapter.)

  Isn’t modern life wonderful? The Java API even has a `Color` class with names like `Color.red` and `Color.black`.

Listing 16-3 has several methods that aren’t really used. For instance, when you implement `MouseListener`, your code has to have its own `mouseReleased` method. You need the `mouseReleased` method not because you’re going to do anything special when the user releases the mouse button, but because you made a promise to the Java compiler and have to keep that promise.
Chapter 17

Writing Java Applets

In This Chapter
- Creating a simple applet
- Building applet animation
- Putting buttons (and other such things) on an applet

With Java’s first big burst onto the scene in 1995, the thing that made the language so popular was the notion of an applet. An applet is a Java program that sits inside a Web browser window. The applet has its own rectangular area on a Web page. The applet can display a drawing, show an image, make a figure move, respond to information from the user, and do all kinds of interesting things. When you put a real live computer program on a Web page, you open up a world of possibilities.

Applets 101

Listings 17-1 and 17-2 show you a very simple Java applet. The applet displays the words Java 2 For Dummies inside a rectangular box. (See Figure 17-1.)

Listing 17-1: An Applet

```java
import javax.swing.JApplet;
import java.awt.Font;
import java.awt.Graphics;

public class SimpleApplet extends JApplet {
    public void init() {
        setContentPane(new DummiesPanel());
    }
}
```
Listing 17-2: Some Helper Code for the Applet

```java
import javax.swing.JPanel;
import java.awt.Font;
import java.awt.Graphics;

class DummiesPanel extends JPanel {
    public void paint(Graphics myGraphics) {
        myGraphics.drawRect(50, 60, 250, 75);
        myGraphics.setFont(new Font("Dialog", Font.BOLD, 24));
        myGraphics.drawString("Java 2 For Dummies", 55, 100);
    }
}
```

When you run the code in Listings 17-1 and 17-2, you don’t execute a `main` method. Instead, you run a Web browser and the Web browser visits an HTML file. The HTML file includes a reference to the applet’s Java code, and the applet appears on your Web page. Listing 17-3 shows a bare minimum HTML file.

Listing 17-3: A One-Line Web Page

```html
<applet code=SimpleApplet width=350 height=200></applet>
```

For more information about HTML files, see Chapter 2.

The easiest way to set things up is to put the HTML file and the applet’s code in the same directory. If you installed JCreator from this book’s CD-ROM, then Listings 17-1, 17-2, and 17-3 are already in one directory on your computer’s hard drive. To run the applet, do the usual Build ➪ Execute Project business. Instead of running a `main` method, JCreator opens a Web browser and visits the HTML file in Listing 17-3.
For instructions on running applets in environments other than JCreator, visit this book’s Web site. At that site, you can also read about the locations of HTML files and applets. (You can find out how to put these files in separate directories, if necessary.)

You can use JCreator’s editor to make your own HTML files. You can create <applet> tags like the one in Listing 17-3. Follow the second set of steps in the section entitled “Storing data in a file” in Chapter 8. To make an HTML file, don’t name your file somedayname.txt. Instead, name your file some-name.htm or some-name.html. With either the .htm or .html extension, JCreator recognizes the presence of a Web page and acts accordingly. (Even without JCreator, you still need the .htm or .html extension. The extension tells your Web browser what to do with your file.)

Waiting to be called

When you look at the code in Listings 17-1 and 17-2, you may notice one thing — an applet doesn’t have a main method. That’s because an applet isn’t a complete program. An applet is a class that contains methods, and your Web browser calls those methods (directly or indirectly). Do you see the init method in Listing 17-1? The browser calls this init method. Then the init method’s call to setContentPane drags in the code from Listing 17-2.

Now, take a look at the paint method in Listing 17-2. The browser calls this paint method automatically, and the paint method tells the browser how to draw your applet on the screen.

For a list of applet methods that your Web browser calls, see the section entitled “The methods in an applet,” later in this chapter. For a bit more information on the paint method and its Graphics parameter, see Chapter 13.

A public class

Notice that the SimpleApplet in Listing 17-1 is a public class. If you create an applet, and you don’t make the class public, you get an Applet not inited or a Loading Java Applet Failed error. To state things very plainly, any class that extends JApplet must be public. If the class isn’t public, your Web browser can’t call the class’s methods.

To state things a little less plainly, a class can have either default access or public access. The only code that can reference a default access class is code that’s in the same package as the default access class. Now remember that your Web browser tries to call methods that are buried inside your applet class. Because the Web browser isn’t likely to be in the same package as your applet (believe me, it’s not), the applet must be public. If the applet
isn’t public, your Web browser’s code (code that’s not in the same package as the applet) can’t call any of your applet’s methods.

For more information on public and default access, see the section entitled “Access Modifiers for Java Classes” in Chapter 15. (You can find Chapter 15 on the CD-ROM.)

The Java API (again)

The code in Listing 17-2 uses a few interesting Java API tricks. Here are some tricks that don’t appear in any earlier chapters:

- **drawRect**: Draws an unfilled rectangle.

  Look at the call to `drawRect` in Listing 17-2. According to that call, the rectangle’s upper-left corner is 50 pixels across and 60 pixels down from the upper-left corner of the panel. The rectangle’s lower-right corner is 250 pixels across and 75 pixels down from the upper-left corner of the panel.

  I wanted the rectangle to surround the words *Java 2 For Dummies*. To come up with numbers for the `drawRect` call, I used trial and error. However, you can make the program figure out how many pixels the words *Java 2 For Dummies* take up. To do this, you need the `FontMetrics` class. (For information on `FontMetrics`, see the Java API documentation.)

- **The Font class**: Describes the features of a character font.

  Listing 17-2 creates a bold, 24-point font with the Dialog typeface style. Other typeface styles include DialogInput, Monospaced, Serif, and SansSerif.

- **drawString**: Draws a string of characters.

  Listing 17-2 draws the string "Java 2 For Dummies" on the face of the panel. The string’s lower-left corner is 55 pixels across and 100 pixels down from the upper-left corner of the panel.

Making Things Move

This section’s applet is cool because it’s animated — you can see an odometer change on the screen. When you look at the code for this applet, you may think the code is quite complicated. Well, in a way, it is. A lot is going on when you use Java to create animation. On the other hand, the code for this applet is mostly boilerplate. To create your own animation, you can borrow most of this section’s code. To see what I’m talking about, look at Listings 17-4 and 17-5.
Listing 17-4: An Odometer Applet

```java
import javax.swing.JApplet;
import javax.swing.Timer;
import java.awt.Color;
import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;

public class Odometer extends JApplet
    implements ActionListener {
    Timer timer;

    public void init() {
        OdometerPanel panel = new OdometerPanel();
        panel.setBackground(Color.white);
        setContentPane(panel);
    }

    public void start() {
        if (timer == null) {
            timer = new Timer(100, this);
            timer.start();
        } else {
            timer.restart();
        }
    }

    public void stop() {
        if (timer != null) {
            timer.stop();
            timer = null;
        }
    }

    public void actionPerformed(ActionEvent e) {
        repaint();
    }
}
```

Listing 17-5: The Odometer Panel

```java
import javax.swing.JPanel;
import java.awt.Font;
import java.awt.Graphics;

class OdometerPanel extends JPanel {
    long hitCount = 239472938472L;
    (continued)
```
Listing 17-5 (continued)

```java
public void paint(Graphics myGraphics) {
    myGraphics.setFont
        (new Font("Monospaced", Font.PLAIN, 24));
    myGraphics.drawString
        ("You are visitor number " +
         Long.toString(hitCount++), 50, 50);
}
```

For a snapshot of the odometer applet in action, see Figure 17-2. Notice the number in the figure. It’s not the same as the starting value of the `hitCount` variable. That’s because, every 250 milliseconds, the applet adds 1 to the value of `hitCount` and displays the new value. The odometer isn’t reporting an honest hit count, but it’s still really cute.

**Figure 17-2:** A popular Web site.

### The methods in an applet

Most of the method names in Listings 17-4 and 17-5 are standard for an applet. The Java API `JApplet` and `JPanel` classes have default declarations for these methods, so you don’t really have to declare these methods yourself. The only methods that you have to put in your code are the methods that you want to customize.

Here’s a list of `JApplet` and `JPanel` methods that your Web browser automatically calls:

- **init:** The browser calls `init` when you first visit the page containing the applet. Imagine that you close the Web browser. Later, you start the browser running again and revisit the page containing the applet. Then the browser calls the applet’s `init` method again.

- **start:** The browser calls `start` right after it calls `init`. If your applet performs any continuous work, you can begin that work’s code in the applet’s `start` method. For instance, if your applet has any animation, the code to begin running that animation is in your `start` method.
The browser calls `paint` right after it calls `start`. The `paint` method has instructions for drawing your applet on the screen. For an explanation, see Chapter 15. (You can find Chapter 15 on the CD-ROM).

The browser can call `paint` several times. For instance, imagine that you cover part of the browser with another window. Or maybe you shrink the browser so that only part of the applet is showing. Later, when you uncover the applet or enlarge the browser window again, the browser calls the panel’s `paint` method.

When the applet’s work should be ceased, the browser calls the `stop` method. Say, for instance, that you click a link that takes you away from the page with the applet on it. Then the browser calls the applet’s `stop` method. Later, when you revisit the page with the applet on it, the browser calls the applet’s `start` method again.

What to put into all these methods

The code in Listings 17-4 and 17-5 uses a standard formula for creating animation inside an applet. Here’s a very brief explanation:

- The applet implements the `ActionListener` interface.
- The `start` method creates a new timer with the following code:
  ```java
  new Timer(100, this)
  ```
  Every 100 milliseconds (every tenth of a second) the timer in Listing 17-4 rings its alarm.

  When it “rings its alarm,” the timer actually gets Java to call an `actionPerformed` method. And whose `actionPerformed` method does Java call? Once again, the keyword `this` answers our question. In Listing 17-4, the word `this` refers to this very same code — this instance of the `Odometer` object that contains the `new Timer(100, this)` call. So every tenth of a second, when the timer rings its alarm, Java calls the `actionPerformed` method in Listing 17-4. How nice and tidy it is!

- The `actionPerformed` method calls the `repaint` method. Under the hood, a call to `repaint` always calls somebody’s `paint` method. In this example, that somebody is the code in Listing 17-5. This `paint` method draws the words “You are visitor number whatever” on the screen.

- At some point, the day is done, and your browser calls the `stop` method. When this happens, the `stop` method tosses the timer into the dumper.

If it weren’t such standard code, I’d feel guilty for explaining this stuff so briefly. But, really, to achieve motion in your own applet, just copy Listings 17-4 and 17-5. Then replace the listing’s `init` and `paint` methods with your own code.
So, what do you put in your init and paint methods?

✔ **If you declare an init method, the method should contain setup code for the applet — stuff that happens once, the first time the applet is loaded.**

In Listing 17-4, the setup code fiddles with a panel:

- It creates a panel by calling the OdometerPanel constructor.
- It makes the panel's background white. (This ensures that the rectangle housing the applet blends nicely with the rest of the Web page.)
- It forges a rock-solid connection between the panel and the applet. It does this by calling the getContentPane method.

✔ The paint method describes a single snapshot of the applet's motion.

In Listing 17-5, the paint method sets the graphics buffer's font, writes the hitCount value on the screen, and then adds 1 to the hitCount. (Who needs real visitors when you can increment your own hitCount variable?)

The value of the hitCount variable starts high and becomes even higher. To store such big numbers, I give hitCount the type long. I use the Long class's toString method to turn hitCount into a string of characters. This toString method is like the Integer class's parseInt method.

I introduce the parseInt method in Chapter 11.

To debug an applet, you can put calls to System.out.println in the applet’s code. If you're running Internet Explorer, the println output appears in something called the Java console. You can see the console by choosing Tools ➪ Sun Java Console from Internet Explorer’s menu bar.

**Responding to Events in an Applet**

This section has an applet with interactive thingamajigs on it. This applet is just like the examples in Chapter 16. In fact, to create Listing 17-7, I started with the code in Listing 16-1. I didn’t do this out of laziness (although, heaven knows, I can certainly be lazy). I did it because applets are so much like Java frames. If you take the code for a frame and trim it down, you can usually create a decent applet.
Listing 17-6: A Guessing Game Applet

```java
import javax.swing.JApplet;
import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;

public class GameApplet extends JApplet {
    public void init() {
        getContentPane().add(new GamePanel());
    }
}
```

Listing 17-7: The Guessing Game Panel

```java
import javax.swing.*;
import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;
import java.util.Random;

class GamePanel extends JPanel implements ActionListener {
    int randomNumber = new Random().nextInt(10) + 1;
    int numGuesses = 0;

    JTextField textField = new JTextField(5);
    JButton button = new JButton("Guess");
    JLabel label = new JLabel(numGuesses + " guesses");

    GamePanel() {
        add(textField);
        add(button);
        add(label);
        button.addActionListener(this);
    }

    public void actionPerformed(ActionEvent e) {
        String textFieldText = textField.getText();
        if (Integer.parseInt(textFieldText) == randomNumber) {
            button.setEnabled(false);
            textField.setText(textField.getText() + " Yes!");
            textField.setEnabled(false);
        } else {
            textField.setText("");
        }
        numGuesses++;
        String guessWord =
            (numGuesses == 1) ? " guess" : " guesses";
        label.setText(numGuesses + guessWord);
    }
}
```
To run the code in Listings 17-6 and 17-7, you need an HTML file:

```html
<applet code="GameApplet" width=225 height=50></applet>
```

Figures 17-3 and 17-4 show you what happens when you run this section’s listings. It’s pretty much the same as what happens when you run the code in Listing 16-1. The big difference is that the applet appears as part of a Web page in a browser window.

Instead of noticing what code Listing 17-7 has, notice what code the listing doesn’t have. To go from Listing 16-1 to Listing 17-7, I remove several lines.

- I don’t bother calling `setLayout`. The default layout for an applet is `FlowLayout`, which is just what I want. If you want info on how `FlowLayout` works, see Chapter 9.
- I don’t call the `pack` method. The width and height fields in the HTML applet tag determine the applet’s size.
- I don’t call the `setVisible` method. An applet is visible by default.
The only other change is between Listings 16-2 and 17-6. Like many other applets, Listing 17-6 has no `main` method. Instead, Listing 17-6 has an `init` method. You don’t need a `main` method, because you never need to say `new GameApplet()` anywhere in your code. The Web browser says it for you. Then, after the Web browser creates an instance of the `GameApplet` class, the browser goes on and calls the instance’s `init` method. That’s the standard scenario for the running of a Java applet.
Chapter 18
Using Java Database Connectivity

In This Chapter
- Connecting to a database
- Inserting values into a database
- Making queries to a database

Whenever I teach Java to professional programmers, I always hear the same old thing. “We don’t need to make any cute little characters fly across the screen. No blinking buttons for us. We need to access databases. Yup, just show us how to write Java programs that talk to databases.”

So here it is, folks — Java Database Connectivity.

Telling the System about Your Database

When I first started working with databases, my toughest problem was connecting to a database. I had written all the Java code. (Well, I had copied all the Java code from some book.) The Java part was easy. The hard part was getting my code to find the database on the system.

Part of the problem was that the way you get your code to talk to the database depends on the kind of system you have and the kind of database that you’re running on your system. The books that I was using couldn’t be too specific on all the details because the details (having nothing to do with Java) varied from one reader’s computer to another.

Well, in this chapter, I make some bold assumptions and try to give you some concrete advice. I assume that you’re running Windows and that you have Microsoft Access installed on your computer. If my assumptions are incorrect, then as far as connecting to the database goes, you’re on your own. (All the Java code in this chapter still works, but you have to tackle the connection problem by yourself.)
Anyway, just follow these steps to create an Access database on a Windows computer:

1. **Choose Start ➪ Settings ➪ Control Panel.**
   
   This opens the Windows Control Panel. What you do next depends on which version of Windows you use.

2. **In Windows 2000, select Administrative Tools. In Windows XP, first select Performance and Maintenance, and then select Administrative Tools.**
   
   Either way, you get a list of tools.

3. **In the Administrative Tools list, double-click Data Sources (ODBC).**
   
   This starts the ODBC Data Source Administrator, which is shown in Figure 18-1.

4. **In the ODBC Data Source Administrator dialog box, select the User DSN tab. Then click the Add button.**
   
   This opens up the Create New Data Source window, which is shown in Figure 18-2.

   If you run into trouble with the User DSN tab, try the System DSN tab instead.

5. **In the Create New Data Source window, select Microsoft Access Driver (*.mdb). Then click Finish.**
   
   Clicking Finish takes you to the ODBC Microsoft Access Setup window, which is shown in Figure 18-3.
6. Type a name in the Data Source Name text box and type a phrase in the Description text box.

   If you want to be consistent with this chapter’s examples, type **AccountDatabase** in the Data Source Name text box. For the Description text box, you can type anything you want. (This chapter’s code doesn’t care what description you type. But for your own sake, type something reasonably descriptive.)

7. **Click the Create button.**

   This opens up the New Database window, which is shown in Figure 18-4.

8. **Browse to the directory where you want your database file to live and type a filename in the Database Name text box.**

   Once again, the Java code doesn’t care what you do here. To keep things tidy, I put the file in a directory named `c:\databases`, but this isn’t crucial at all. The only thing that matters is that you keep the file’s `.mdb` extension. (Otherwise, your system has trouble remembering that this is a Microsoft Access database.)
9. Click OK. When you see a message box saying that the database .mdb file was successfully created, click OK. Back in the ODBC Microsoft Access Setup window, click OK.

Finally, back in the ODBC Data Source Administrator dialog box, notice that your new AccountDatabase has been created (and click OK). See Figure 18-5.

That’s great. Now you’re ready to run some Java database code.
Creating Data

For the code that you’re about to explore, the formal name is *Java Database Connectivity* (JDBC). Using JDBC, you issue database commands through Java code. The crux of JDBC is in two packages: `java.sql` and `javax.sql`, which are both in the Java API. This chapter’s examples use the classes in `java.sql`. The first example is in Listing 18-1.

**Listing 18-1: Creating a Table; Inserting Data**

```java
import java.sql.DriverManager;
import java.sql.Statement;
import java.sql.Connection;
import java.sql.SQLException;

class CreateTable {
    public static void main(String args[]) throws SQLException, ClassNotFoundException {
        Class.forName("sun.jdbc.odbc.JdbcOdbcDriver");
        Connection connection = DriverManager.getConnection("jdbc:odbc:AccountDatabase");
        Statement statement = connection.createStatement();
        statement.executeUpdate("create table ACCOUNTS"
                               + "(NAME VARCHAR(32) NOT NULL PRIMARY KEY,
                                  ADDRESS VARCHAR(32),
                                  BALANCE FLOAT)");
        statement.executeUpdate("insert into ACCOUNTS values
                                 ('Barry Burd', '222 Cyberspace Lane', 24.02)");
        statement.executeUpdate("insert into ACCOUNTS values
                                 ('Jane Public', '111 Consumer Street', 55.63)");
        statement.close();
        connection.close();
    }
}
```
When you run the code in Listing 18-1, nothing seems to happen. The program starts running and then stops running. That’s about it. The code has no visible output, because all the output goes to a database. So, to see the result of running the code in Listing 18-1, you have to look for changes in the database itself.

If you followed the instructions in this chapter’s first section and created a Microsoft Access database, you can use Access to examine your database. What you see is in Figure 18-6.

**Using SQL commands**

In Listing 18-1, the heart of the code is in three calls to `executeUpdate`. Each `executeUpdate` call contains a string — a normal, Java, double-quoted string of characters. To keep the code readable, I’ve chopped each string into parts. I separate the parts with plus signs (Java’s string concatenation operator).

Java’s plus sign does double duty. For numbers, the plus sign performs addition. For strings, the plus sign squishes two strings together, creating one big, combined string.

You can make a double-quoted string as long as you like. When you get to the right edge of your screen, just keep typing. If you want to see the whole string without scrolling, however, you can break the string into pieces, as I did in Listing 18-1. Just separate the pieces with plus signs.

You cannot break a Java string into pieces by just pressing Enter and moving to the next line. When you start a string with the double-quote (“”), the ending double-quote must be on the same line of code.

If you’re familiar with SQL (the *Structured Query Language*), then the command strings in the calls to `executeUpdate` make sense to you. If not, then pick up a copy of *SQL For Dummies*, 5th Edition, by Allen G. Taylor (from Wiley Publishing, Inc.). One way or another, don’t go fishing around this chapter for explanations of `create table` and `insert into`. You won’t find the explanations, because these command strings aren’t part of Java. These
commands are just strings of characters that you feed to the `executeUpdate` method. These strings, which are written in SQL, create a new database table and add rows of data to the table. When you write a Java database program, that’s what you do. You write ordinary SQL commands and surround those commands with calls to Java methods.

The code in this chapter adheres strictly to the techniques defined in JDBC version 1.0. Later versions of the JDBC classes support something called *scrollable result sets*. With a scrollable result set, you have methods like `insertRow` — methods that save you the effort of writing complete SQL command strings.

### Connecting and disconnecting

Aside from the calls to method `executeUpdate`, the code in Listing 18-1 is cut-and-paste stuff. Here’s a rundown on what each part of the code means:

- **Class.forName**: Find a database driver.

  To talk to a database, you need an intermediary piece of software. That intermediary is called a *database driver*. Drivers come in all shapes and sizes, and most of them are quite expensive. Java, however, comes with a small, freebie driver — the JDBC-ODBC Bridge. The JDBC-ODBC Bridge turns Java database commands into ODBC (*Open Database Connectivity*) commands. Because ODBC is quite common, your computer probably understands these translated ODBC commands.

  Anyway, the code for the JDBC-ODBC Bridge is kept in the `JdbcOdbcDriver` class (which is a Java class). This class lives inside the `sun.jdbc.odbc` package.

  To use this `JdbcOdbcDriver` class, you call the `Class.forName` method. Believe it or not, the Java API has a class named `Class`. The `Class` class contains information about classes that are available to the Java Virtual Machine (JVM). In Listing 18-1, the call to `Class.forName` looks for the `sun.jdbc.odbc.JdbcOdbcDriver` class. After a `JdbcOdbcDriver` instance is loaded, you can proceed to connect with a database.

- **DriverManager.getConnection**: Establish a session with a particular database.

  If you use Windows and Microsoft Access, you may have followed the instructions in this chapter’s first section. In following those instructions, you told your computer about a thing called *AccountDatabase*. Well, at this point in the Java code, you’re opening up a connection to *AccountDatabase*. You’re doing this with the aid of the `DriverManager` class.
In the parameter for `getConnection` (refer to Listing 18-1), notice the colons. The code doesn’t simply name the `AccountDatabase`, it tells the `DriverManager` class what protocols to use to connect with the database. The code `jdbc:odbc:` — which is the same as the `http:` in a Web address — tells the computer to use the `jdbc` protocol to talk to the `odbc` protocol, which in turn talks directly to your `AccountDatabase`.

- `connection.createStatement`: Make a statement.

It seems strange, but in Java Database Connectivity, you create a single `statement` object. After you’ve created a statement object, you can use that object many times, with many different SQL strings, to issue many different commands to the database. So, before you start calling the `statement.executeUpdate` method, you have to create an actual `statement` object. The call to `connection.createStatement` creates that `statement` object for you.

- `SQLException` and `ClassNotFoundException`: Acknowledge exceptions that can be thrown in the code.

If you read Chapter 12, you know that some method calls throw checked exceptions. A `checked exception` is one that has to be acknowledged somewhere in the calling code. Well, a call to `Class.forName` can throw a `ClassNotFoundException`, and just about everything else in Listing 18-1 can throw an `SQLException`. To acknowledge these exceptions, I top off my `main` method with a nice `throws` clause.

- `close`: Release resources.

As Ritter always says, you’re not being considerate of others if you don’t clean up your own messes. Every connection and every database statement lock up some system resources. When you’re finished using these resources, you need to release them. If you don’t do this by making explicit calls to `close` methods, the system has to figure out on its own that you’re finished with these resources. Because this “figuring stuff out on its own” business is hit or miss, the best thing to do is to put `close` calls in your code.

---

**Retrieving Data**

What good is a database if you can’t get data from it? In this section, you query the database that you created in Listing 18-1. The code to issue the query is in Listing 18-2.
Listing 18-2: Making a Query

```java
class GetData {
    public static void main(String args[])
        throws SQLException, ClassNotFoundException {
            NumberFormat currency =
            NumberFormat.getCurrencyInstance();
            Class.forName("sun.jdbc.odbc.JdbcOdbcDriver");
            Connection connection = DriverManager.getConnection
                        ("jdbc:odbc:AccountDatabase");
            Statement statement = connection.createStatement();
            ResultSet resultset =
            statement.executeQuery("select * from ACCOUNTS");
            while(resultset.next()) {
                out.print(resultset.getString("NAME"));
                out.print(\t);  
                out.print(resultset.getString("ADDRESS"));
                out.print(\t);  
                out.println
                (currency.format(resultset.getFloat("BALANCE")));
            }
            resultset.close();
            statement.close();
            connection.close();
    }
}
```

A run of the code from Listing 18-2 is shown in Figure 18-7. The code queries the database and then steps through the rows of the database, printing the data from each of the rows.
Listing 18-2 starts with the usual calls to `forName`, `getConnection`, and `createStatement`. Then the code calls `executeQuery` and supplies the call with an SQL command. For those who know SQL commands, this particular command gets all data from the ACCOUNTS table (the table that you create in Listing 18-1).

The thing returned from calling `executeQuery` is of type `java.sql.ResultSet`. (That's the difference between `executeUpdate` and `executeQuery` — `executeQuery` returns a result set, and `executeUpdate` doesn't.) This result set is very much like a database table. Like the original table, the result set is divided into rows and columns. Each row contains the data for one account. Each row has a name, an address, and a balance amount.

After you've called `executeQuery` and gotten your result set, you can step through the result set one row at a time. To do this, you go into a little loop and test the condition `resultset.next()` at the top of each loop iteration. Each time around, the call to `resultset.next()` does two things:

- It moves you to the next row of the result set (the next account) if another row exists.
- It tells you whether or not another row exists by returning a boolean value — `true` or `false`.

If the condition `resultset.next()` is true, the result set had another row. The computer moved to that other row, so you can march into the body of the loop and scoop data from that row. On the other hand, if `resultset.next()` is false, the result set doesn't have any more rows. You jump out of the loop and start closing everything.

Now, imagine that the computer is pointing to a row of the result set, and you're inside the loop in Listing 18-2. Then you're retrieving data from the result set's row by calling the result set's `getString` and `getFloat` methods. Back in Listing 18-1, you set up the ACCOUNTS table with the columns NAME, ADDRESS, and BALANCE. So, here in Listing 18-2, you're getting data from these columns by calling your `getSomeTypeOrOther` methods and feeding the original column names to these methods. After you have the data, you display the data on the computer screen, with a tab separating each piece of information.
For a review of the \t tab sequence, see Chapter 11.

Each Java ResultSet instance has several nice getSomeTypeOrOther methods. Depending on the type of data you put into a column, you can call methods getArray, getBigDecimal, getBlob, getInt, getObject, getTimestamp, and several others.
