

IDENTIFICATION

Product Code: MAINDEC-9A-D0CA-D

Product Name: Memory Address Test

Date: June 15, 1967

Maintainer: Diagnostics Group

Author: Edward P. Steinberger

1 ABSTRACT

The Memory Address Test checks the memory system of the PDP-9 to ensure that all memory locations not occupied by the program in a given 8K memory stack can be uniquely addressed. It does this by writing the address of a memory location into itself and checking to see that it is there. The complement of the address is also written to ensure that all bits of a word can be accessed. Checks are also made to ensure that only one memory location is written into whenever memory is addressed, and that cores of different memory locations are not shorted together inside the memory stack. Errors are indicated to the operator via the teleprinter.

2 REQUIREMENTS

Equipment

Standard PDP-9 Computer

Storage

The program uses all of 8K memory for the program or as a test area. The program occupies memory from location 17200 to 17777 and tests all locations below 17200.

3 LOADING PROCEDURE

Method

Put HRI tape of program in reader.

Set ADDRESS SWITCHES to 17200.

Depress I/O RESET.

Depress and release READIN key.

4 STARTING PROCEDURE

4.1 Control Switch Settings

The following is a table of accumulator switch settings and their action on the program.

| AC Switch | Set As | Action |
|-----------|--------|--------------------------|
| 0 | 1 | Halt on error |
| | 0 | Don't halt on error |
| 1 | 1 | Don't print errors |
| | 0 | Print errors |
| 2 | 1 | Ring bell on error |
| | 0 | Ring bell after N passes |

| AC Switch | Set As | Action |
|-----------|--------|--|
| 3 | 1 0 | Loop on current number (address or complement) |
| 4 | 1 0 | Loop on current location |
| 5 | 1 0 | Loop on current test |
| 6 | 1 0 | Skip 1's in 0's test (Test 4) |
| 7 | 1 0 | Halt after completing all tests |

Switch 3 operates only with the first test, switch 4 with first and fourth, 3 has precedence over 4 (in first test), and 4 over 5 (in first and fourth tests). N is an arbitrary number (initially 20000_8) for the first and fourth tests, and 4_8 for the second and third. It may be changed at the operator's discretion by modifying the contents of locations 17302 and 17300 respectively to the appropriate LAW-N instruction.

4.2 Starting Address

The starting address of the program is 17200. The restart addresses are 17200, 17262, 17320, and 17367 (see listing).

4.3 Program and/or Operator Action

Set ADDRESS SWITCHES to 17200.

Set ACCUMULATOR SWITCHES to desired positions (see section 4.1). Normal setting is 500000.

Depress I/O RESET.

Depress START.

5 OPERATING PROCEDURE

5.1 Operational Switch Settings

See section 4.1

5.2 Program and/or Operator Action

- a. To put the program in the 'SCOPE mode, the ACCUMULATOR SWITCHES should be set to 260000 (don't halt, don't print, bell after N passes, loop on current number, loop on current location).

- b. To test an individual location (first test), store the address to be tested, in location 17765 (POINT) and restart the computer at location 17211 (FIRST+7) to store the address in itself, or location 17224 (SECOND) to store the complement (1's) in the address. ACCUMULATOR SWITCHES should be set to 260000 (see a).
- c. To run the Individual Location test (whole first test), restart the computer at location 17200 (FIRST-2) with AC Switches 3 and 4 a 0 and 5 a 1.
- d. To narrow the first test to less than all of memory occupied by the program, place the new upper limit in location 17773 (UPLIM), then start the computer at location 17200 (FIRST-2).
- e. To test all of memory in the forward direction only, restart the computer at location 17262 (THIRD) with AC switch 5 = 1.
- f. To test all of memory in the reverse direction only, restart the computer at location 17320 (FIFTH) with AC switch 5 = 1.
- g. To narrow the second and third tests to less than all of memory not occupied by the program, place the new upper limit in location 17774 (UPLIM1), then restart at the appropriate address for the particular test. Checks will still be made starting from location 00000 up to the limit for the forward test, or from the limit down to location 00000 for the reverse test.
- h. To write 1's into a particular memory location (fourth test) store the address to contain all 1's in location 17764 (PNTR1) and restart the computer at location 17374 (SEVENH+5) with AC switch 4 = 1.
- i. To narrow the fourth test to less than all of memory occupied by the program, place the new upper limit in location 17773 (UPLIM), then start the computer at the appropriate starting address. Checks will still be made starting from location 00000 up to the limit.
- j. To run the Write 1's in a Field of 0's test (fourth test), restart the computer at location 17367 (SEVENH) with AC switch 5 = 1.

6 ERRORS

Unless AC switch 1 is a 1, all errors will be printed on the teleprinter.

6.1 Error Halts and Description

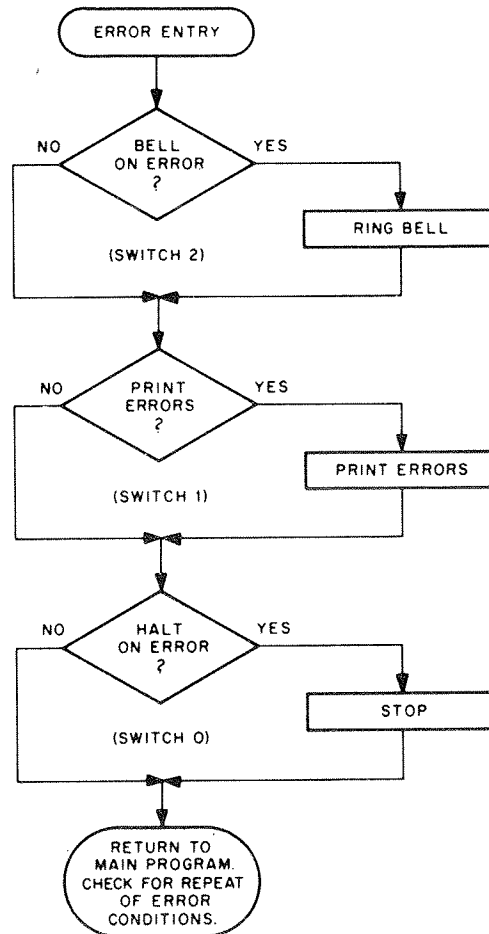

There is only one error halt in the program at location 17526. This halt will occur any time there is an error; there is no useful information in the AC. The computer will halt at location 17472 if all tests are not repeated.

6.2 Error Recovery

If AC switch 0 = 1, the computer will halt on an error. To recover and repeat the failure, reset AC switches 0 to 5 as necessary (see section 4.1) and then depress CONTINUE.

To test a particular location, see section 5.2.

6.3 Error Switch Hierarchy

6.4 Error Timeout Examples

6.4.1 Individual Location Test

| ADDRESS | GOOD | BAD |
|---------|--------|--------|
| 001234 | 001234 | 001230 |

The above example shows that location 1234 dropped bit 15 when its ADDRESS was written in it.

6.4.2 Forward Write-Read and Reverse Complement Write-Read Tests (both typeouts are the same).

Forward Write-Read Test

| ADDRESS | GOOD | BAD |
|---------|--------|--------|
| 001234 | 001234 | 003234 |

The above example shows that location 1234 contained 3234 when it should have contained 001234. This may have been due to "picking up" bit 7 in the memory buffer register when addressing location 001234, or it may have been due to "double addressing" (addressing location 001234 when the memory address register contains 001234 and 003234).

6.4.3 Write 1's in a Field of 0's Test

WRITE ONES IN A FIELD OF ZEROS

| ADDRESS | GOOD | BAD |
|---------|--------|--------|
| 001234 | 000000 | 000004 |
| 001235 | 000000 | 000004 |

The above example shows that location 01234 contained 000004 when it should have contained 000000. This may have been due to bit 15 of location 01234 being shorted to bit 15 of location 01235. This same error may have caused location 01235 to be in error. If location 17764 (PNTR1) contained 01235 at the first error and 01234 at the second error, this is probably true.

7 EXECUTION TIME

Tests 1, 2 and 3 - Insignificant

Test 4 - 20 minutes

8 PROGRAM DESCRIPTION

There are four basic parts to the program. The first tests each memory location, not occupied by the program, to assure that all bits of each may be accessed. It does this by first writing the address of a location in itself, and then checking to see if it was properly written. The 1's complement of the address is then written into the same location and checked, to assure that all bits of a memory location may be written and read. The second portion writes sequential addresses into their respective memory locations in the forward direction for all of memory not occupied by the program, and then each location is checked in the forward direction to assure that it contains its own address. The third portion writes the complement of each address not occupied by the program into sequential memory locations respectively in the reverse direction (from the highest location down to the lowest) and then checks each of the locations in the reverse direction to ensure that it contains its respective address complemented.

- e. The internal pointer is then set back to 0.
- f. The number which has been stored in the location specified by the pointer is obtained and checked to see that it is correct.
- g. The pointer is then incremented and (f) is repeated until all memory locations have been checked. Any error causes typeout on the teleprinter.
- h. A check is then made to see if this test should be repeated (switch 5). If so, the program goes to (b). If not, the program goes on to the next portion.

8.3 Reverse - Complement Write-Read Test

- a. The first function performed is that of initialization. Several message header locations are initialized.
- b. An internal pointer for the program is initialized to the first location under the program (17177).
- c. The number which is in the internal pointer is obtained, complemented (1's) and then stored in the memory location specified by the pointer.
- d. The pointer is then decremented (1 is subtracted from it) and (c) is repeated until all memory locations have had the complement addresses stored in them.
- e. The internal pointer is then set back to 17177.
- f. The number which has been stored in the location specified by the pointer is obtained and checked to see that it is correct.
- g. The pointer is then decremented and (f) is repeated until all memory locations have been checked. Any error causes typeout on the teleprinter.
- h. A check is then made to see if this test should be repeated (switch 5). If so, the program goes to (b). If not, the program goes to (i).
- i. A check is then made to see if the next test should be skipped (switch 6). If so, the program goes to 8.1 (a). If not, the computer goes to 8.4 (a).

8.4 Write 1's in a Field of 0's Test

- a. The first function performed is that of initialization. Several message header locations are initialized.
- b. The all 1's pointer is set to 0.
- c. All of memory tested is then cleared.
- d. All 1's is then stored in the location pointed to by the all 1's points.
- e. A memory pointer is then set to 00000.
