5 DEVELOPMENT SUPPORT TOOLS FOR SERIES MELPS 7700

RASM77	MELPS 7700 Relocatable Macro Assembler	5-3
C77	MELPS 7700 C Compiler	5-5
RTT77	MELPS 7700 Real-Time Tracer	5-7
SDB77	MELPS 7700 Symbolic Debugger	5-8
MR7700KIT	MELPS 7700 Real-Time OS Development KIT	5-10
MR7700SRC	MELPS 7700 Real-Time OS Source KIT	5-12
PC4000E	Debugging Machine	5-13
PC4000P	Power Supply for PC4000E	5-15
PC4816	MELPS 7700 Debugging Machine	5-16
PCA4800M	1M Byte Memory Expansion Board for PC4816	5-20
M37700T-RTT	MELPS 7700 Common Option Board (Real-Time Tracer, Correspond to PC4000E)	5-21
M37700T-POD	MELPS 7700 Emulation Pod (Single-Chip Mode, Correspond to PC4000E)	5-22
M37700TX-POD	MELPS 7700 Emulation Pod (Microprocessor Mode, Correspond to PC4000E)	5-23
M37700T-HPD	MELPS 7700 High Level Emulation POD (Correspond to PC4816)	5-24
M37702T-HPD	MELPS 7700 High Level Emulation POD (Correspond to PC4816)	5-25
M37704T-HPD	MELPS 7700 High Level Emulation POD (Correspond to PC4816)	5-26
M37720T-HPD	MELPS 7700 High Level Emulation POD (Correspond to PC4816)	5-27
M37795T-HPD	MELPS 7700 High Level Emulation POD (Correspond to PC4816)	5-28
M37796T-HPD	MELPS 7700 High Level Emulation POD (Correspond to PC4816)	5-29
PCA4707	Program Writing Adapter for One time PROM Version Microcomputers	5-30
PCA4708	Program Writing Adapter for EPROM Version Microcomputers	5-31
PCA4709	Program Writing Adapter for PROM Version Microcomputers	5-32
PCA4774	Program Writing Adapter for One time PROM Version Microcomputers	5-33
PCA4780	Pitch Converter for 80-pin Flat Package	5-34
PCA4990	Program Writing Adapter for Versatile Memory	5-35
PCA7780G02	Pitch Converter for 80-pin Flat Package	5-36

ORDERING INFORMATION

FUNCTION CODE

Mitsubishi integrated circuit may be ordered using the following simplified alphanumeric type-codes which define the function of the IC/LSIs and the package style.

For Mitsubishi Original Products

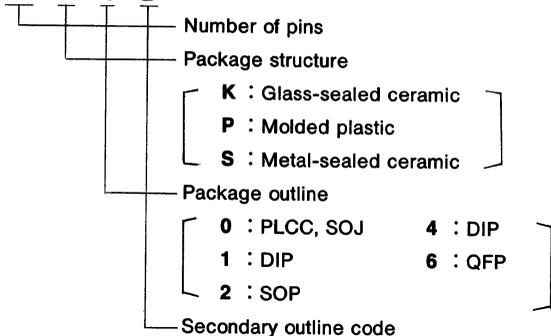

Example : **M 3 77 00 E 4 - 001 FP**

PACKAGE CODE

Package style may be specified by using the following simplified alphanumeric code.

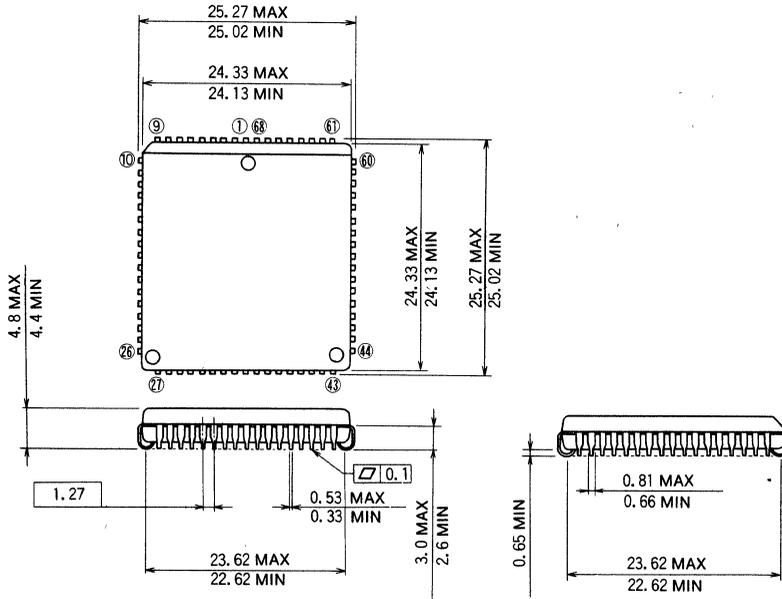

Example : **42 P 4 B**

Special-purpose secondary codes describing outline are included as necessary. For details, contact your sales representative.

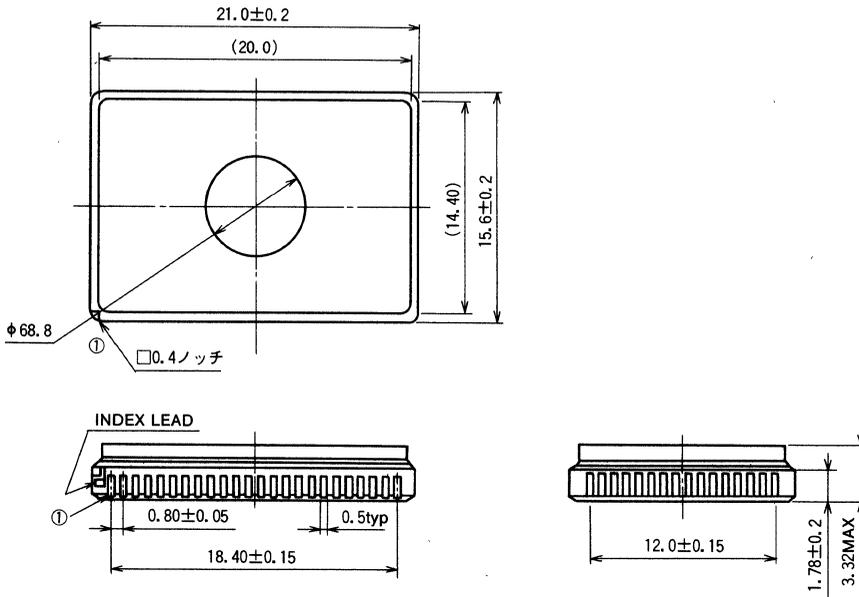

TYPE 68P0 68-PIN MOLDED PLASTIC LEADED CHIP CARRIER

Dimension in mm

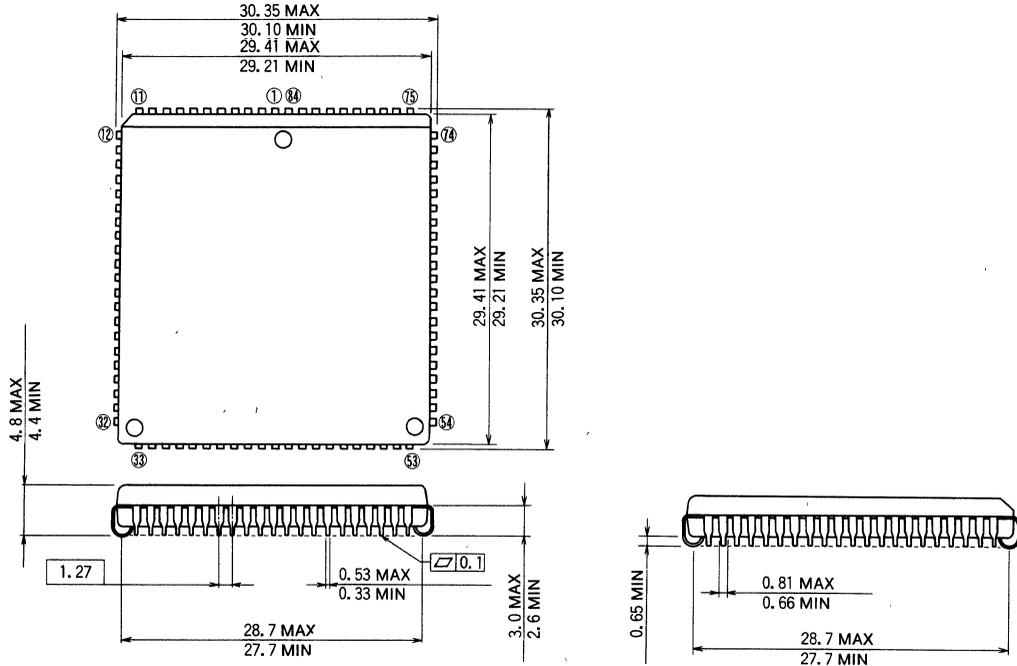

TYPE 80D0 80PIN CERAMIC LCC

Dimension in mm

TYPE 84PO 84-PIN MOLDED PLASTIC LEADED CHIP CARRIER

Dimension in mm

LETTER SYMBOLS FOR THE DYNAMIC PARAMETERS

b) those that are characteristics of the memory.
 The letter symbols so far proposed for memory circuits are listed in sub-clauses 3.1 and 3.2 below.
 All subscripts A should be in lower-case.

3.1. Timing Requirements

The letter symbols for the timing requirements of semiconductor memories are as follows:

Term	Subscript
Cycle time	c
Time interval between two signal events	d
Fall time	f
Hold time	h
Precharging time	pc
Rise time	r
Recovery time	rec
Refresh time interval	rf
Setup time	su
Transition time	t
Pulse duration (width)	w

3.2. Characteristics

The letter symbols for the dynamic characteristics of semiconductor memories are as follows:

Characteristic	Subscript
Access time	a
Disable time	dis
Enable time	en
Propagation time	P
Recovery time	rec
Transition time	T
Valid time	v

Note Recovery time for use as a characteristic is limited to sense recovery time

4. SUBSCRIPTS B AND D (For Signal Name or Terminal Name)

The letter symbols for the signal name or the name of the terminal are as given below.

All subscripts B and D should be in upper-case.

Signal or terminal	Subscript
Address	A
Clock	C
Column address	CA
Column address strobe	CAS
Data input	D
Data input/output	DQ
Chip enable	E

Erasure	ER
Output enable	G
Program	PR
Data output	Q
Read	R
Row address	RA
Row address strobe	RAS
Refresh	RF
Read/Write	RW
Chip select	S
Write (write enable)	W

Note 1 In the letter symbols for time intervals, bars over the subscripts, for example CAS, should not be used

2 It should be noted, when further letter symbols are chosen, that the subscript should not end with H, K, V, X, or Z (See clause 5)

3 If the same terminal, or signal, can be used for two functions (for example Data input/output, Read/Write) the waveform should be labelled with the dual function, if appropriate, but the symbols for the dynamic parameters should include only that part of the subscript relevant to the parameter

5. SUBSCRIPTS C AND E (For Transition of Signal)

The following symbols are used to represent the level or state of a signal:

Transition of signal	Subscript
High logic level	H
Low logic level	L
Valid steady-state level (either low or high)	V
Unknown, changing, or 'don't care' level	X
High-impedance state of three-state output	Z

The direction of transition is expressed by two letters, the direction being from the state represented by the first letter to that represented by the second letter, with the letters being as given above.

When no misunderstanding can occur, the first letter may be omitted to give an abbreviated symbol for subscripts C and E as indicated below.

All subscripts C and E should be in upper-case.

Examples	Subscript	
	Full	Abbreviated
Transition from high level to low level	HL	L
Transition from low level to high level	LH	H
Transition from unknown or changing state to valid state	XV	V
Transition from valid state to unknown or changing state	VX	X
Transition from high-impedance state to valid state	ZV	V

Note Since subscripts C and E may be abbreviated, and since subscripts B and D may contain an indeterminate number of letters, it is necessary to put the restriction on the subscripts B and D that they should not end with H, L, V, X, or Z, so as to avoid possible confusion

FOR DIGITAL INTEGRATED CIRCUITS

New symbol	Former symbol	Parameter—definition
C_i		Input capacitance
C_o		Output capacitance
$C_{i\ o}$		Input/output terminal capacitance
$C_i(\phi)$		Input capacitance of clock input
f		Frequency
$f(\phi)$		Clock frequency
I		Current—the current into an integrated circuit terminal is defined as a positive value and the current out of a terminal is defined as a negative value
I_{BB}		Supply current from V_{BB}
$I_{BB(AV)}$		Average supply current from V_{BB}
I_{CC}		Supply current from V_{CC}
$I_{CC(AV)}$		Average supply current from V_{CC}
$I_{CC(PD)}$		Power down supply current from V_{CC}
I_{DD}		Supply current from V_{DD}
$I_{DD(AV)}$		Average supply current from V_{DD}
I_{GG}		Supply current from V_{GG}
$I_{GG(AV)}$		Average supply current from V_{GG}
I_i		Input current
I_{IH}		High level input current—the value of the input current when V_{OH} is applied to the input considered
I_{IL}		Low level input current—the value of the input current when V_{OL} is applied to the input considered
I_{OH}		High level output current—the value of the output current when V_{OH} is applied to the output considered
I_{OL}		Low level output current—the value of the output current when V_{OL} is applied to the output considered
I_{OZ}		Off state (high impedance state) output current—the current into an output having a three-state capability with input condition so applied that it will establish according to the product specification, the off (high-impedance) state at the output
I_{OZH}		Off state (high impedance state) output current, with high level voltage applied to the output
I_{OZL}		Off-state (high impedance state) output current, with low-level voltage applied to the output
I_{OS}		Short-circuit output current
I_{SS}		Supply current from V_{SS}
P_d		Power dissipation
N_{EW}		Number of erase/write cycles
N_{RA}		Number of read access unrefreshed
R_i		Input resistance
R_L		External load resistance
R_{OFF}		Off state output resistance
R_{ON}		On-state output resistance
t_a		Access time—the time interval between the application of a specified input pulse during a read cycle and the availability of valid data signal at an output
$t_a(A)$	$t_a(AD)$	Address access time—the time interval between the application of an address input pulse and the availability of valid data signals at an output
$t_a(CAS)$		Column address strobe access time
$t_a(E)$	$t_a(CE)$	Chip enable access time
$t_a(G)$	$t_a(OE)$	Output enable access time
$t_a(PR)$		Data access time after program
$t_a(RAS)$		Row address strobe access time
$t_a(S)$	$t_a(OS)$	Chip select access time
t_c		Cycle time
t_{CR}	$t_c(RD)$	Read cycle time—the time interval between the start of a read cycle and the start of the next cycle
t_{CRF}	$t_c(REF)$	Refresh cycle time—the time interval between successive signals that are intended to restore the level in a dynamic memory cell to its original level
t_{CPG}	$t_c(PG)$	Page-mode cycle time
t_{CRMW}	$t_c(RMR)$	Read-modify-write cycle time—the time interval between the start of a cycle in which the memory is read and new data is entered, and the start of the next cycle
t_{CW}	$t_c(WR)$	Write cycle time—the time interval between the start of a write cycle and the start of the next cycle

New symbol	Former symbol	Parameter—definition
$t_{su}(D)$	$t_{su}(DA)$	Data-in setup time
$t_{su}(D-E)$	$t_{su}(DA-CE)$	Chip enable setup time before data-in
$t_{su}(D-W)$	$t_{su}(DA-WR)$	Write setup time before data-in
$t_{su}(E)$	$t_{su}(CE)$	Chip enable setup time
$t_{su}(E-P)$	$t_{su}(CE-P)$	Precharge setup time before chip enable
$t_{su}(G-E)$	$t_{su}(OE-CE)$	Chip enable setup time before output enable
$t_{su}(P-E)$	$t_{su}(P-CE)$	Chip enable setup time before precharge
$t_{su}(PD)$		Power-down setup time
$t_{su}(R)$	$t_{su}(RD)$	Read setup time
$t_{su}(R-CAS)$	$t_{su}(RA-CAS)$	Column address strobe setup time before read
$t_{su}(RA-CAS)$		Column address strobe setup time before row address
$t_{su}(S)$	$t_{su}(CS)$	Chip select setup time
$t_{su}(S-W)$	$t_{su}(CS-WR)$	Write setup time before chip select
$t_{su}(W)$	$t_{su}(WR)$	Write setup time
t_{THL}		High-level to low-level transition time } the time interval between specified reference points on the edge of the output pulse when the output is going to the low (high) level and when a specified input signal is applied through a specified network and the output is loaded by another specified network
t_{TLH}		
$t_v(A)$	$t_{dv}(AD)$	Data valid time after address
$t_v(E)$	$t_{dv}(CE)$	Data valid time after chip enable
$t_v(E)PR$	$t_v(CE)PR$	Data valid time after chip enable in program mode
$t_v(G)$	$t_v(OE)$	Data valid time after output enable
$t_v(PR)$		Data valid time after program
$t_v(S)$	$t_v(CS)$	Data valid time after chip select
t_w		Pulse width (pulse duration) the time interval between specified reference points on the leading and trailing edges of the waveforms
$t_w(E)$	$t_w(CE)$	Chip enable pulse width
$t_w(EH)$	$t_w(CEH)$	Chip enable high pulse width
$t_w(EL)$	$t_w(EL)$	Chip enable low pulse width
$t_w(PR)$		Program pulse width
$t_w(R)$	$t_w(RD)$	Read pulse width
$t_w(S)$	$t_w(CS)$	Chip select pulse width
$t_w(W)$	$t_w(WR)$	Write pulse width
$t_w(\phi)$		Clock pulse width
T_a		Ambient temperature
T_{opr}		Operating temperature
T_{stg}		Storage temperature
V_{BB}		V_{BB} supply voltage
V_{CC}		V_{CC} supply voltage
V_{DD}		V_{DD} supply voltage
V_{GG}		V_{GG} supply voltage
V_i		Input voltage
V_{IH}		High-level input voltage—the value of the permitted high-state voltage at the input
V_{IL}		Low-level input voltage—the value of the permitted low-state voltage at the input
V_o		Output voltage
V_{OH}		High-level output voltage—the value of the guaranteed high-state voltage range at the output
V_{OL}		Low-level output voltage—the value of the guaranteed low-state voltage range at the output
V_{SS}		V_{SS} supply voltage

MITSUBISHI MICROCOMPUTERS QUALITY ASSURANCE AND RELIABILITY TESTING

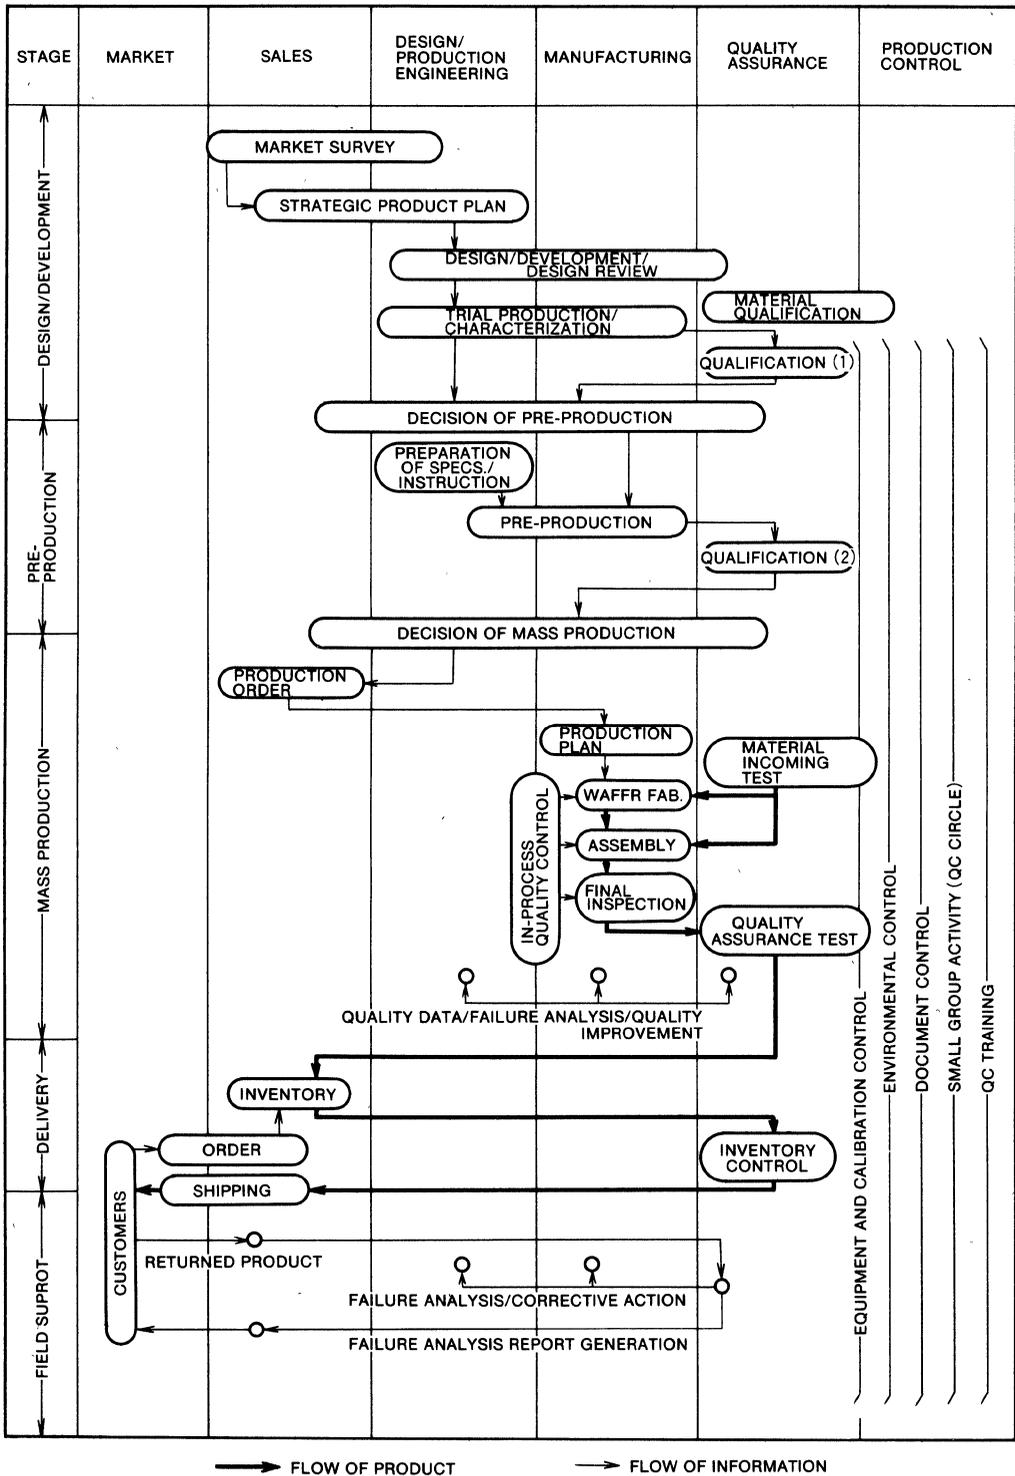

Fig.1 FLOW CHART OF QUALITY ASSURANCE SYSTEM

MITSUBISHI MICROCOMPUTERS QUALITY ASSURANCE AND RELIABILITY TESTING

3 RELIABILITY TEST RESULTS

The reliability test results for Mitsubishi Single-chip 16-bit Microcomputers are shown in Table 2.

Table 2 shows the result of endurance tests of high temper-

ature operation life and high temperature storage life test and the results of the environment tests of thermal stress, high temperature/high humidity and pressure cooker test for the single-chip 16-bit Microcomputer.

Table 2 ENDURANCE and ENVIRONMENTAL TEST RESULTS

Test	Series	Type Number	Test Condition	Number of Samples	Device Hours (Hours)	Number of Failures
High Temperature Operation Life	MELPS 7700	M37700E4-XXXFP M37700M2-XXXFP M37700M4-XXXFP	125°C 7 V	266	266000	0

Temperature Cycling	MELPS 7700	M37700M2-XXXFP M37700M4-XXXFP	-65°C 30min	76	0	0	0
			150°C 30min				

(3) Destructive Failure by Electrical Overstress

Surge voltage marginal tests have been performed to reproduce the electrical overstress failure in field uses. Figure 9 and Figure 10 are examples of failure observed by surge voltage test. The trace of destruction is verified as the aluminum bridge by X-ray micro analysis.

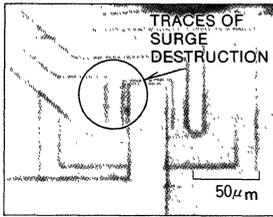

Fig.9 Micrograph of surge voltage destruction

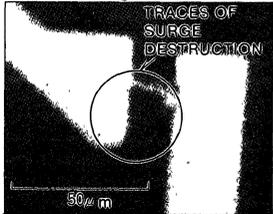

Fig.10 Aluminum trace of destructive spot

(4) Aluminum Electromigration

Figure 11 shows an open circuit of aluminum metallization in high current density region caused by accelerated operation life test. This failure is due to aluminum electromigration. Voids and hillock have been formed in aluminum metallization by high current density operation.

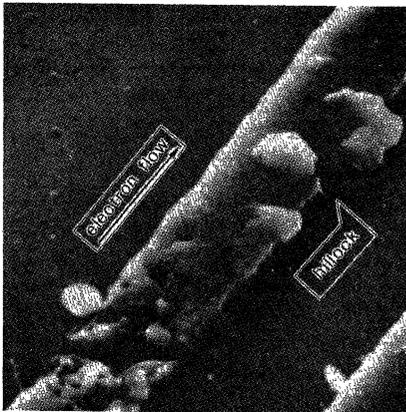

Fig.11 Voids and hillocks formation by Aluminum electromigration

5 SUMMARY

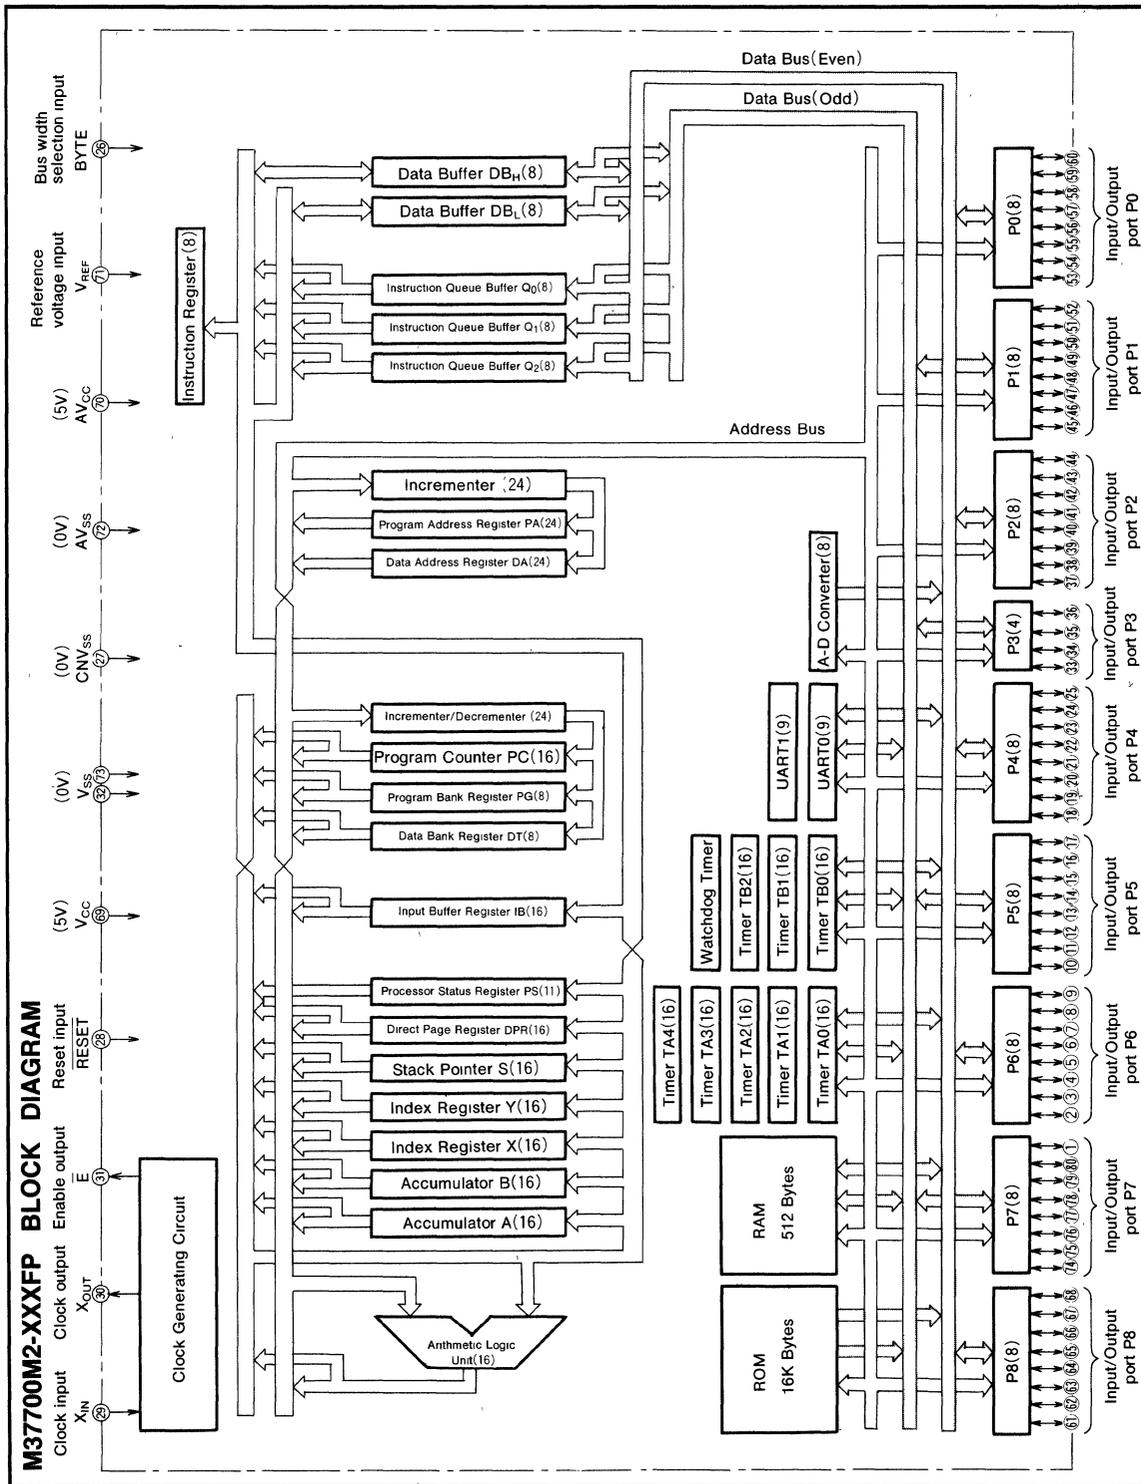

The Mitsubishi quality assurance system and examples of reliability control have been discussed. The customer's interests and requirements for high reliability IC & LSI are increasing significantly. To satisfy customer's expectancy, Mitsubishi as an IC vendor, would like to make perpetual efforts in the following areas.

- (1) Emphasis on built-in reliability at design stage and reliability evaluation to investigate latent failure modes and acceleration factors.
- (2) Execution of periodical endurance, environment and mechanical test to verify reliability target and realize higher reliability.
- (3) Focus on development of advanced failure analysis techniques. Detail failure analysis, intensive corrective action and quick response to customer's analysis request.
- (4) Collection of customer's quality data in qualification, incoming inspection, production and field use to improve PPM, fraction defective and FIT, failure rate.

Mitsubishi would highly appreciate if the customer would provide quality and reliability data of incoming inspection or field failure rate essential to verify and improve the quality/reliability of IC & LSI.

PIN DESCRIPTION

Pin	Name	Input/Output	Functions
V _{CC} , V _{SS}	Power supply		Supply 5 V±10% to V _{CC} and 0 V to V _{SS} .
CNV _{SS}	CNV _{SS} input	Input	This pin controls the processor mode. Connect to V _{SS} for single-chip mode, and to V _{CC} for external ROM types.
RESET	Reset input	Input	To enter the reset state, this pin must be kept at a "L" condition should be maintained for the required time.
X _{IN}	Clock input	Input	These are I/O pins of internal clock generating circuit. Connect a ceramic or quartz crystal resonator between X _{IN} and X _{OUT} . When an external clock is used, the clock source should be connected to the X _{IN} pin and the X _{OUT} pin should be left open.
X _{OUT}	Clock output	Output	
\bar{E}	Enable output	Output	Data or instruction read and data write are performed when output from this pin is "L"
BYTE	Bus width selection input	Input	In memory expansion mode or microprocessor mode, this pin determines whether the external data bus is 8-bit width or 16-bit width. The width is 16 bits when "L" signal inputs and 8 bits when "H" signal inputs.
AV _{CC} , AV _{SS}	Analog supply input		Power supply for the A-D converter. Connect AV _{CC} to V _{CC} and AV _{SS} to V _{SS} externally.
V _{REF}	Reference voltage input	Input	This is reference voltage input pin for the A-D converter.
P0 ₀ ~P0 ₇	I/O port P0	I/O	In single-chip mode, port P0 becomes an 8-bit I/O port. An I/O directional register is available so that each pin can be programmed for input or output. These ports are in input mode when reset. Address (A ₇ ~A ₀) is output in memory expansion mode or microprocessor mode.
P1 ₀ ~P1 ₇	I/O port P1	I/O	In single-chip mode, these pins have the same functions as port P0. When the BYTE pin is set to "L" in memory expansion mode or microprocessor mode and external data bus is 16-bit width, high-order data (D ₁₅ ~D ₈) is input or output when \bar{E} output is "L" and an address (A ₁₅ ~A ₈) is output when \bar{E} output is "H". If the BYTE pin is "H" that is an external data bus is 8-bit width, only address (A ₁₅ ~A ₈) is output.
P2 ₀ ~P2 ₇	I/O port P2	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode low-order data (D ₇ ~D ₀) is input or output when \bar{E} output is "L" and an address (A ₂₃ ~A ₁₆) is output when \bar{E} output is "H".
P3 ₀ ~P3 ₃	I/O port P3	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode, R/W, BHE, ALE, and HLDA signals are output.
P4 ₀ ~P4 ₇	I/O port P4	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode, P4 ₀ and P4 ₄ become HOLD and RDY input pin respectively. Functions of other pins are the same as in single-chip mode. Port P4 ₂ can be programmed for ϕ_1 output pin divided the clock to X _{IN} pin by 2.
P5 ₀ ~P5 ₇	I/O port P5	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as I/O pins for timer A0, timer A1, timer A2, and timer A3.
P6 ₀ ~P6 ₇	I/O port P6	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as I/O pins for timer A4, external interrupt input INT ₀ , INT ₁ , and INT ₂ pins, and input pins for timer B0, timer B1, and timer B2.
P7 ₀ ~P7 ₇	I/O port P7	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as analog input AN ₀ ~AN ₇ input pins. P7 ₇ also has an A-D conversion trigger input function.
P8 ₀ ~P8 ₇	I/O port P8	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as RxD, TxD, CLK, CTS/RTS pins for UART 0 and UART 1.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

STACK POINTER (S)

Stack pointer (S) is an 16-bit register. It is used during a subroutine call or interrupts. It is also used during stack, stack pointer relative, or stack pointer relative indirect indexed Y addressing mode.

PROGRAM COUNTER (PC)

Program counter (PC) is a 16-bit counter that indicates the low-order 16 bits of the next program memory address to be executed. This is a bus interface unit between the program memory and the CPU, so that the program memory is accessed through bus interface unit. This is described later.

PROGRAM BANK REGISTER (PG)

Program bank register is an 8-bit register that indicates the high-order 8 bits of the next program memory address to be executed. When a carry occurs by incrementing the contents of the program counter, the contents of the program bank register (PG) is incremented by 1. Also, when a carry or borrow occurs after adding or subtracting the offset value to or from the contents of the program counter (PC) using branch instruction, the contents of the program bank register (PG) is incremented or decremented by 1 so that programs can be written without worrying about bank boundaries.

DATA BANK REGISTER (DT)

Data bank register (DT) is an 8-bit register. With some addressing modes, a part of the data bank register (DT) is used to specify a memory address. The contents of data bank register (DT) is used as the high-order 8 bits of a 24-bit address. Addressing modes that use the data bank register (DT) are direct indirect, direct indexed X indirect, direct indirect indexed Y, absolute, absolute bit, absolute indexed X, absolute indexed Y, absolute bit relative, and stack pointer relative indirect indexed Y.

DIRECT PAGE REGISTER (DPR)

Direct page register (DPR) is a 16-bit register. Its contents is used as the base address of a 256-byte direct page area. The direct page area is allocated in bank 0, but when the contents of DPR is FF01₁₆ or greater, the direct page area spans across bank 0 and bank 1. All direct addressing modes use the contents of the direct page register (DPR) to generate the data address. If the low-order 8 bits of the direct page register (DPR) is "00₁₆", the number of cycles required to generate an address is minimized. Normally the low-order 8 bits of the direct page register (DPR) is set to "00₁₆".

PROCESSOR STATUS REGISTER (PS)

Processor status register (PS) is an 11-bit register. It consists of a flag to indicate the result of operation and CPU interrupt levels.

Branch operations can be performed by testing the flags C, Z, V, and N.

The details of each processor status register bit are described below.

1. Carry flag (C)

The carry flag contains the carry or borrow generated by the ALU after an arithmetic operation. This flag is also affected by shift and rotate instructions. This flag can be set and reset directly with the SEC and CLC instructions or with the SEP and CLP instructions.

2. Zero flag (Z)

This zero flag is set if the result of an arithmetic operation or data transfer is zero and reset if it is not. This flag can be set and reset directly with the SEP and CLP instructions.

3. Interrupt disable flag (I)

When the interrupt disable flag is set to "1", all interrupts except watchdog timer, DBC, and software interrupt are disabled. This flag is set to "1" automatically when these is an interrupt. It can be set and reset directly with the SEI and CLI instructions or SEP and CLP instructions.

4. Decimal mode flag (D)

The decimal mode flag determines whether addition and subtraction are performed as binary or decimal. Binary arithmetic is performed when this flag is "0". If it is "1", decimal arithmetic is performed with each word treated as two or four digit decimal. Arithmetic operation is performed using four digits when the data length flag m is "0" and with two digits when it is "1". (Decimal operation is possible only with the ADC and SBC instructions.) This flag can be set and reset with the SEP and CLP instructions.

MITSUBISHI MICROCOMPUTERS

M37700SFP, M37700SAFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

The bus interface unit operates using one of the waveforms (1) to (6) shown in Figure 5. The standard waveforms are (1) and (2).

The ALE signal is used to latch only the address signal from the multiplexed signal containing data and address.

The \bar{E} signal becomes "L" when the bus interface unit reads an instruction code or data from memory or when it writes data to memory. Whether to perform read or write is controlled by the R/W signal. Read is performed when the R/W signal is "H" state and write is performed when it is "L" state.

Waveform (1) in Figure 5 is used to access a single byte or two bytes simultaneously. To read or write two bytes simultaneously, the first address accessed must be even. Furthermore, when accessing an external memory area in memory expansion mode or microprocessor mode, set the bus width selection input pin BYTE to "L". (external data bus width to 16 bits) The internal memory area is always treated as 16-bit bus width regardless of BYTE.

When performing 16-bit data read or write, if the conditions for simultaneously accessing two bytes are not satisfied, waveform (2) is used to access each byte one by one. However, when prefetching the instruction code, if the address of the instruction code is odd, waveform (1) is used, and only one byte is read in the instruction queue buffer.

The signals A_0 and \bar{BHE} in Figure 5 are used to control these cases: 1-byte read from even address, 1-byte read from odd address, 2-byte simultaneous read from even and odd addresses, 1-byte write to even address, 1-byte write to odd address, or 2-byte simultaneous write to even and odd addresses. The A_0 signal that is the address bit 0 is "L" when an even number address is accessed. The \bar{BHE} signal becomes "L" when an odd number address is accessed.

The bit 2 of processor mode register (address $5E_{16}$) is the wait bit. When this bit is set to "0", the ALE signal and \bar{E} signal are extended and the access time is doubled when accessing an external memory area in memory expansion mode or microprocessor mode. However, these signals are not extended when an internal memory area is accessed. When the wait bit is "1", the access time is not extended for any access. Waveform (3) is an expansion of waveform (1). Waveform (4), (5), and (6) are expansion of the entire waveform (2), first half of waveform (2), and the last half of waveform (2) respectively.

Instruction code read, data read, and data write are described below.

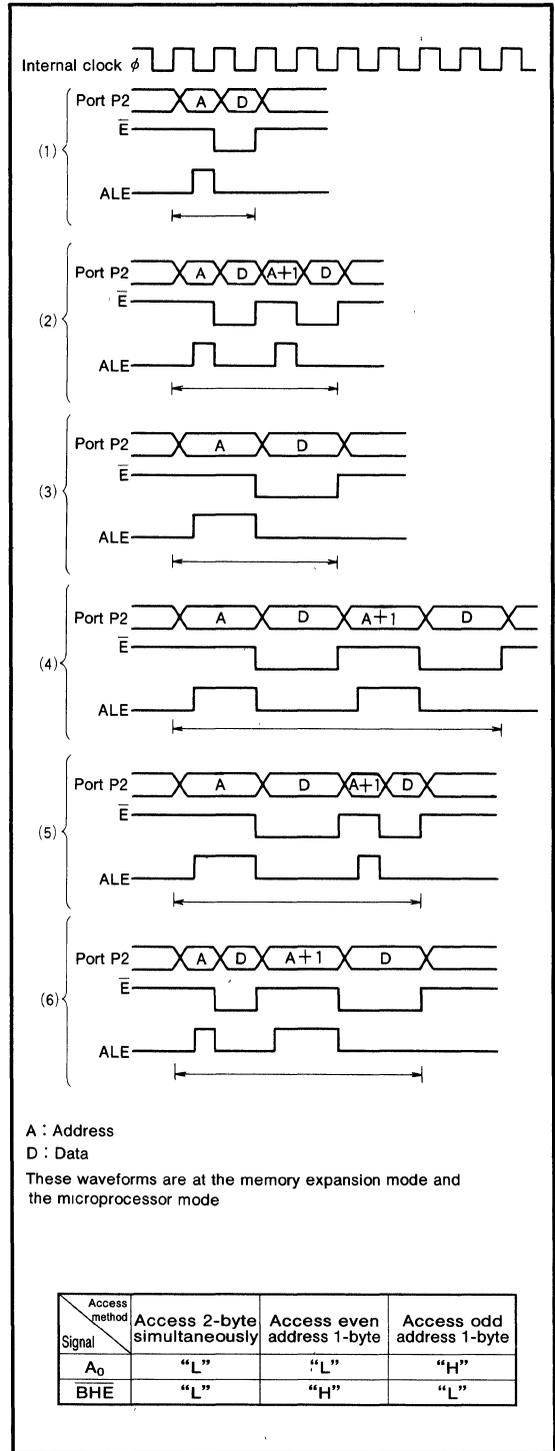

Fig. 5 Relationship between access method and signals A_0 and \bar{BHE}

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

INTERRUPTS

Table 1 shows the interrupt types and the corresponding interrupt vector addresses. Reset is also treated as a type of interrupt and is discussed in this section, too.

\overline{DBC} is an interrupt used during debugging.

Interrupts other than reset, \overline{DBC} , watchdog timer, zero divide, and BRK instruction all have interrupt control registers. Table 2 shows the addresses of the interrupt control registers and Figure 6 shows the bit configuration of the interrupt control register.

The interrupt request bit is automatically cleared by the hardware during reset or when processing an interrupt. Also, interrupt request bits other than \overline{DBC} and watchdog timer can be cleared by software.

INT_2 to INT_0 are external interrupts and whether to cause an interrupt at the input level (level sense) or at the edge (edge sense) can be selected with the level sense/edge sense selection bit. Furthermore, the polarity of the interrupt input can be selected with polarity selection bit.

Timer and UART interrupts are described in the respective section.

The priority of interrupts when multiple interrupts are caused simultaneously is partially fixed by hardware, but, it can also be adjusted by software as shown in Figure 7. The hardware priority is fixed the following:

reset > \overline{DBC} > watchdog timer > other interrupts

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

As shown in Figure 9, there are three different interrupt priority resolution time from which one is selected by software. After the selected time has elapsed, the highest priority is determined and is processed after the currently executing instruction has been completed.

The time is selected with bits 4 and 5 of the processor mode register (address 5E₁₆) shown in Figure 10. Table 4 shows the relationship between these bits and the number of cycles. After a reset, the processor mode register is initialized to "00₁₆" and therefore, the longest time is selected.

However, the shortest time may be selected by software.

Table 3. Value set in processor interrupt level(IPL) during an interrupt

Interrupt types	Setting value
Reset	0
DBC	7
Watchdog timer	7
Zero divide	Not change value of IPL.
BRK instruction	Not change value of IPL.

Table 4. Relationship between priority level evaluation time selection bit and number of cycles

Priority level resolution time selection bit		Number of cycles
Bit 5	Bit 4	
0	0	7 cycles of ϕ
0	1	4 cycles of ϕ
1	0	2 cycles of ϕ

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

When bit 2 of the timer Ai mode register is "1", the output is generated from TAI_{OUT} pin. The output is toggled each time the contents of the counter reaches to 0000₁₆. When the contents of the count start flag is "0", "L" is output from TAI_{OUT} pin.

When bit 2 is "0", TAI_{OUT} can be used as a normal port pin. When bit 4 is "0", TAI_{IN} can be used as a normal port pin. When bit 4 is "1", counting is performed only while the input signal from the TAI_{IN} pin is "H" or "L" as shown in Figure 14. Therefore, this can be used to measure the pulse width of the TAI_{IN} input signal. Whether to count while the input signal is "H" or while it is "L" is determined by bit 3. If bit 3 is "1", counting is performed while the TAI_{IN} pin input

signal is "H" and if bit 3 is "0", counting is performed while it is "L".

Note that the duration of "H" or "L" on the TAI_{IN} pin must be two or more cycles of the timer count source.

When data is written to timer Ai register, the same data is also written to the reload register and the counter. The count start flag corresponding to the written timer is cleared to "0" and count is stopped. The contents of the counter can be read at any time.

When the value set in the timer Ai register is n, the timer frequency dividing ratio is 1/(n+1).

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

(2) Event counter mode [01]

Figure 15 shows the bit configuration of the timer Ai mode register during event counter mode. In event counter mode, the bit 0 of the timer Ai mode register must be "1" and bit 1 and 5 must be "0".

The input signal from the TAI_{IN} pin is counted when the count start flag shown in Figure 13 is "1" and counting is stopped when it is "0".

Count is performed at the falling edge of the input signal when bit 3 is "0" and at the rising edge of the signal when it is "1".

In event counter mode, whether to increment or decrement the count can be selected with the up-down flag or the input signal from the TAI_{OUT} pin.

When bit 4 of the timer Ai mode register is "0", the up-down flag is used to determine whether to increment or decrement the count (decrement when the flag is "0" and increment when it is "1"). Figure 16 shows the bit configuration of the up-down flag.

When bit 4 of the timer Ai mode register is "1", the input signal from the TAI_{OUT} pin is used to determine whether to increment or decrement the count. However, note that bit 2 must be "0" if bit 4 is "1" because if bit 2 is "1", TAI_{OUT} pin becomes an output pin with pulse output.

Also, the increment or decrement count interval must be at least two cycles of the timer count source.

The count is decremented when the input signal from the TAI_{OUT} pin is "L" and incremented when it is "H".

An interrupt request signal is generated and the interrupt request bit in the timer Ai interrupt control register is set when the counter reaches 0000₁₆ (decrement count) or FFFF₁₆ (increment count). At the same time, the contents of the reload register is transferred to the counter and the count is continued.

At decrement count, if bit 2 is "1", the output is generated from the TAI_{OUT} pin. The output is toggled each time the counter reaches 0000₁₆. At increment count, if bit 2 is "1", the output is generated from the TAI_{OUT} pin. The output is toggled each time the counter reaches FFFF₁₆.

If bit 2 is "0", TAI_{OUT} pin can be used as a normal port pin. However, if bit 4 is "1" and the TAI_{OUT} pin is used as an output pin, the output from the pin changes the count direction. Therefore, bit 4 should be "0" unless the output from the TAI_{OUT} pin is to be used to select the count direction.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

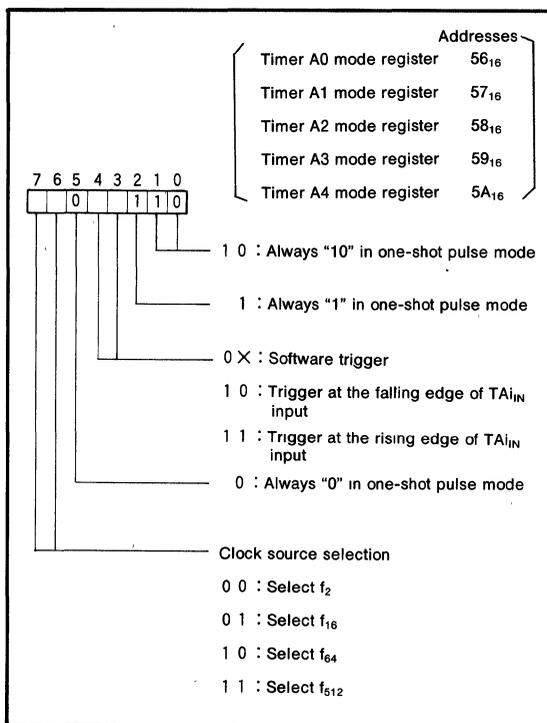

Fig. 18 Timer Ai mode register bit configuration during one-shot pulse mode

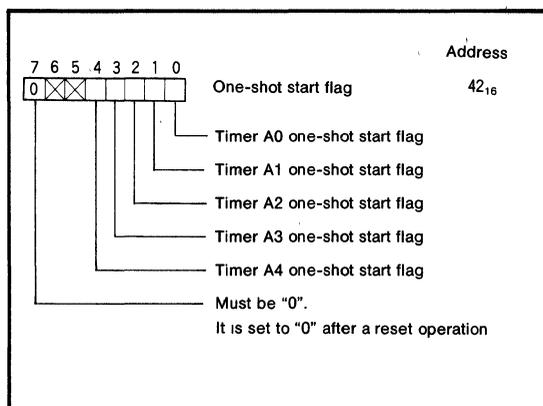

Fig. 19 One-shot start flag bit configuration

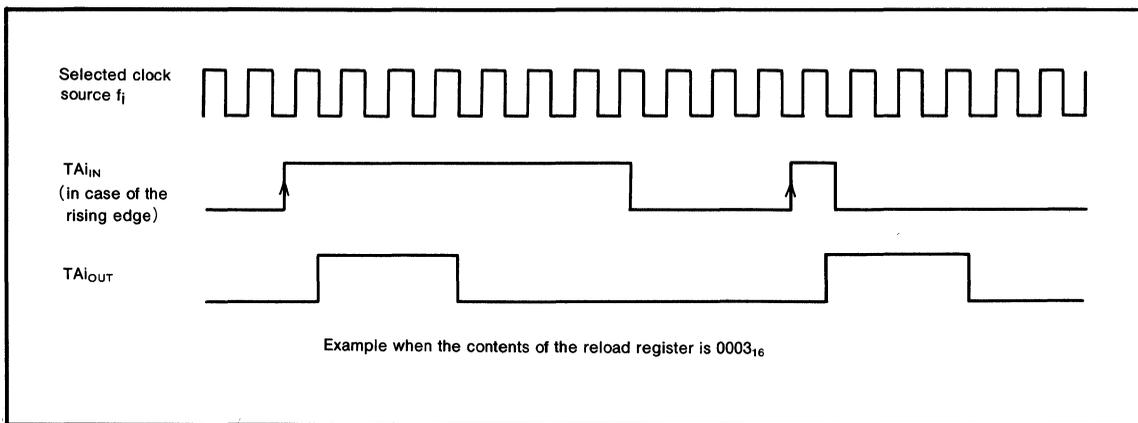

Fig. 20 Pulse output example when external rising edge is selected

(4) Pulse width modulation mode [11]

Figure 22 shows the bit configuration of the timer Ai mode register during pulse width modulation mode. In pulse width modulation mode, bits 0, 1, and 2 must be set to "1". Bit 5 is used to determine whether to perform 16-bit length pulse width modulator or 8-bit length pulse width modulator. 16-bit length pulse width modulator is performed when bit 5 is "0" and 8-bit length pulse width modulator is performed when it is "1". The 16-bit length pulse width modulator is described first.

The pulse width modulator can be started with a software trigger or with an input signal from a TAI_{IN} pin (external trigger).

The software trigger mode is selected when bit 4 is "0". Pulse width modulator is started and pulse is output from TAI_{OUT} when the timer Ai start flag is set to "1".

The external trigger mode is selected when bit 4 is "1". Pulse width modulator starts when a trigger signal is input from the TAI_{IN} pin when the timer Ai start flag is "1". Whether to trigger at the fall or rise of the trigger signal is determined by bit 3. The trigger is at the fall of the trigger signal when bit 3 is "0" and at the rise when it is "1".

If data is written in timer Ai when the timer Ai start flag is "0" (that is when pulse width modulator is halted), the data is written in the reload register and the counter. Then when the time Ai start flag is set to "1" and a software trigger or an external trigger is issued to start modulation, the waveform shown in Figure 23 is output continuously. Once modulation is started, triggers are not accepted. If the value in the reload register is m, the duration "H" of pulse is

$$\frac{1}{\text{selected clock frequency}} \times m$$

and the output pulse period is

$$\frac{1}{\text{selected clock frequency}} \times (2^{16} - 1).$$

An interrupt request signal is generated and the interrupt request bit in the timer Ai interrupt control register is set at each fall of the output pulse.

To change the pulse width, write the data during the time after the pulse falls but before the rise of the next pulse. In contrast to the timer mode, data is written in the reload register only and not in the counter. Furthermore, the timer Ai start flag is unaffected and the counter is not stopped.

The contents of the reload register are transferred to the counter just before the rise of the next pulse so that the pulse width is changed from the next output pulse.

To read the timer Ai is performed from the reload register instead of the counter.

The 8-bit length pulse width modulator is described next.

The 8-bit length pulse width modulator is selected when the timer Ai mode register bit 5 is "1".

The reload register and the counter are both divided into 8-bit halves.

The low order 8 bits function as a prescaler and the high

order 8 bits function as the 8-bit length pulse width modulator. The prescaler counts the clock selected by bits 6 and 7. A pulse is generated when the counter reaches 0000₁₆ as shown in Figure 24. At the same time, the contents of the reload register is transferred to the counter and count is continued.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

TIMER B

Figure 25 shows a block diagram of timer B.

Timer B has three modes; timer mode, event counter mode, and pulse period measurement/pulse width measurement mode. The mode is selected with bits 0 and 1 of the timer Bi mode register ($i = 0$ to 2). Each of these modes is described below.

(1) Timer mode [00]

Figure 26 shows the bit configuration of the timer Bi mode register during timer mode. Bits 0, and 1 of the timer Bi mode register must always be "0" in timer mode.

Bits 6 and 7 are used to select the clock source. The counting of the selected clock starts when the count start flag "1" and stops when "0".

As shown in Figure 13, the timer Bi count start flag is at the same address as the timer Ai count start flag. The count is decremented, an interrupt occurs, and the interrupt request bit in the timer Bi interrupt control register is set when the contents becomes 0000_{16} . At the same time, the contents of the reload register is stored in the counter and count is continued.

Timer Bi does not have a pulse output function or a gate function like timer A.

When data is written to timer Bi register, the same data is written to the reload register and the counter. The count start flag of the corresponding to the written timer is cleared to "0" and count is stopped. The contents of the counter can be read at any time.

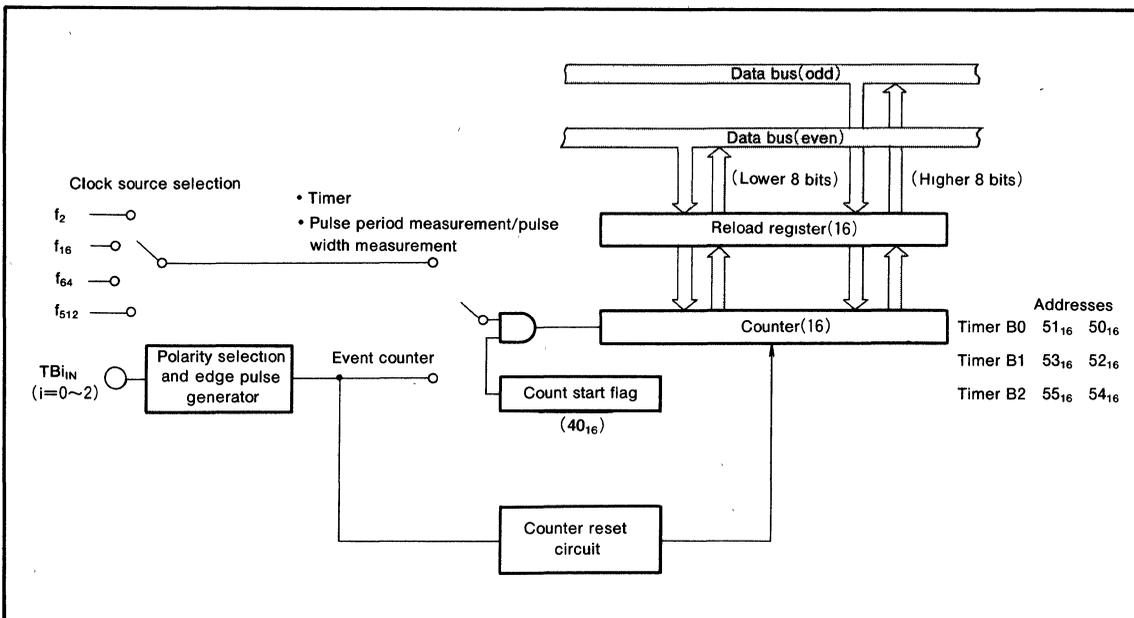

Fig. 25 Timer B block diagram

MITSUBISHI MICROCOMPUTERS
M37700M2-XXXFP, M37700M2AXXFP
M37700SFP, M37700SAFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

After the contents of the counter is transferred to the reload register, an interrupt request signal is generated and the interrupt request bit in the timer Bi interrupt control register is set. However, no interrupt request signal is generated when the contents of the counter is transferred first time to the reload register after the count start flag is set to "1". When bit 3 is "1", the pulse width measurement mode is selected. Pulse width measurement mode is similar to pulse period measurement mode except that the clock is

counted from the fall of the TBi_{IN} pin input signal to the next rise or from the rise of the input signal to the next fall as shown in Figure 30.

When timer Bi is read, the contents of the reload register is read.

Note that in this mode, the interval between the fall of the TBi_{IN} pin input signal to the next rise or from the rise to the next fall must be at least two cycles of the timer count source.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

Bit 6 is the parity bit selection bit which indicates whether to add parity bit or not.

Bits 4 to 6 should be set or reset according to the data format of the communicating devices.

Bit 7 is the sleep selection bit. The sleep mode is described later.

The UART_i transmit/receive control register 0 bit 2 is used to determine whether to use $\overline{\text{CTS}}_i$ input or RTS_i output. $\overline{\text{CTS}}_i$ input used if bit 2 is "0" and RTS_i output is used if bit 2 is "1".

If $\overline{\text{CTS}}_i$ input is selected, the user can control whether to stop or start transmission by external $\overline{\text{CTS}}_i$ input. RTS_i will be described later.

Transmission

Transmission is started when the bit 0 (TE_i flag) of UART_i transmit/receive control register 1 is "1", the bit 1 (TI_i flag) is "0", and $\overline{\text{CTS}}_i$ input is "L" if $\overline{\text{CTS}}_i$ input is selected. As shown in Figure 38 and 39, data is output from the TxD_i pin with the stop bit and parity bit specified by the bits 4 to 6 of UART_i transmit/receive mode register bits. The data is output from the least significant bit.

The TI_i flag indicates whether the transmission buffer is empty or not. It is cleared to "0" when data is written in the transmission buffer and set to "1" when the contents of the transmission buffer register is transferred to the transmission register.

When the transmission register becomes empty after the contents has been transmitted, data is transferred automatically from the transmission buffer register to the transmission register if the next transmission start condition is satisfied.

Once transmission has started, the TE_i flag, TI_i flag, and $\overline{\text{CTS}}_i$ signal (if $\overline{\text{CTS}}_i$ input is selected) are ignored until data transmission is completed.

Therefore, transmission does not stop until it completes even if the TE_i flag is cleared during transmission.

The transmission start condition indicated by TE_i flag, TI_i flag, and $\overline{\text{CTS}}_i$ is checked while the T_{ENDi} signal shown in Figure 38 is "H". Therefore, data can be transmitted continuously if the next transmission data is written in the transmission buffer register and TI_i flag is cleared to 0 before the T_{ENDi} signal goes "H".

The bit 3 (TxEMPTY_i flag) of UART_i transmit/receive control register 0 changes to "1" at the next cycle after the T_{ENDi} signal goes "H" and changes to "0" when transmission starts. Therefore, this flag can be used to determine whether data transmission is completed.

When the TI_i flag changes from "0" to "1", the interrupt request bit in the UART_i transmission interrupt control register is set to "1".

Receive

Receive is enabled when the bit 2 (RE_i flag) of UART_i transmit/receive control register 1 is set. As shown in Figure 40, the frequency divider circuit at the receiving end begin to work when a start bit is arrived and the data is received.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

A-D CONVERTER

The A-D converter is an 8-bit successive approximation converter.

Figure 41 shows a block diagram of the A-D converter and Figure 42 shows the bit configuration of the A-D control register. The frequency of the A-D converter operating clock ϕ_{AD} is selected by the bit 7 of the A-D control register. When bit 7 is "0", ϕ_{AD} is the clock frequency divided by 8. That is, $\phi_{AD} = f(X_{IN})/8$. When bit 7 is "1", ϕ_{AD} is the clock frequency divided by 4 and $\phi_{AD} = f(X_{IN})/4$. The ϕ_{AD} during A-D conversion must be 250KHz minimum because the comparator consists of a capacity coupling amplifier.

The operating mode is selected by the bits 3 and 4 of A-D control register. The available operating modes are one-shot, repeat, single sweep, and repeat sweep.

The bit of data direction register bit corresponding to the A-D converter pin must be "0" (input mode) because the analog input port is shared with port P7.

The operation of each mode is described below.

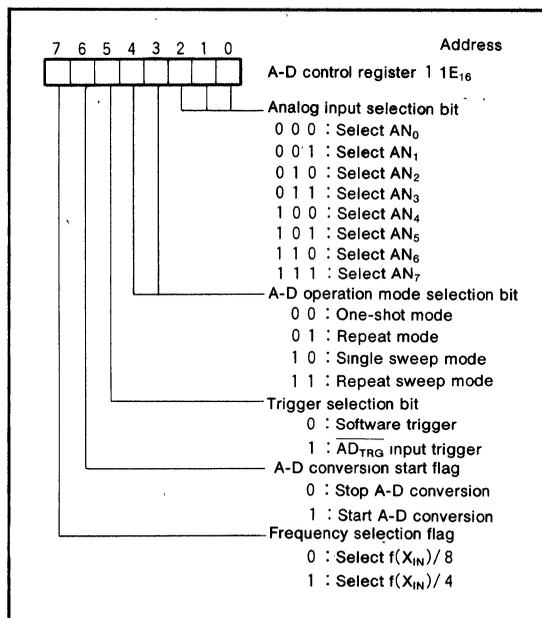

Fig. 42 A-D control register bit configuration

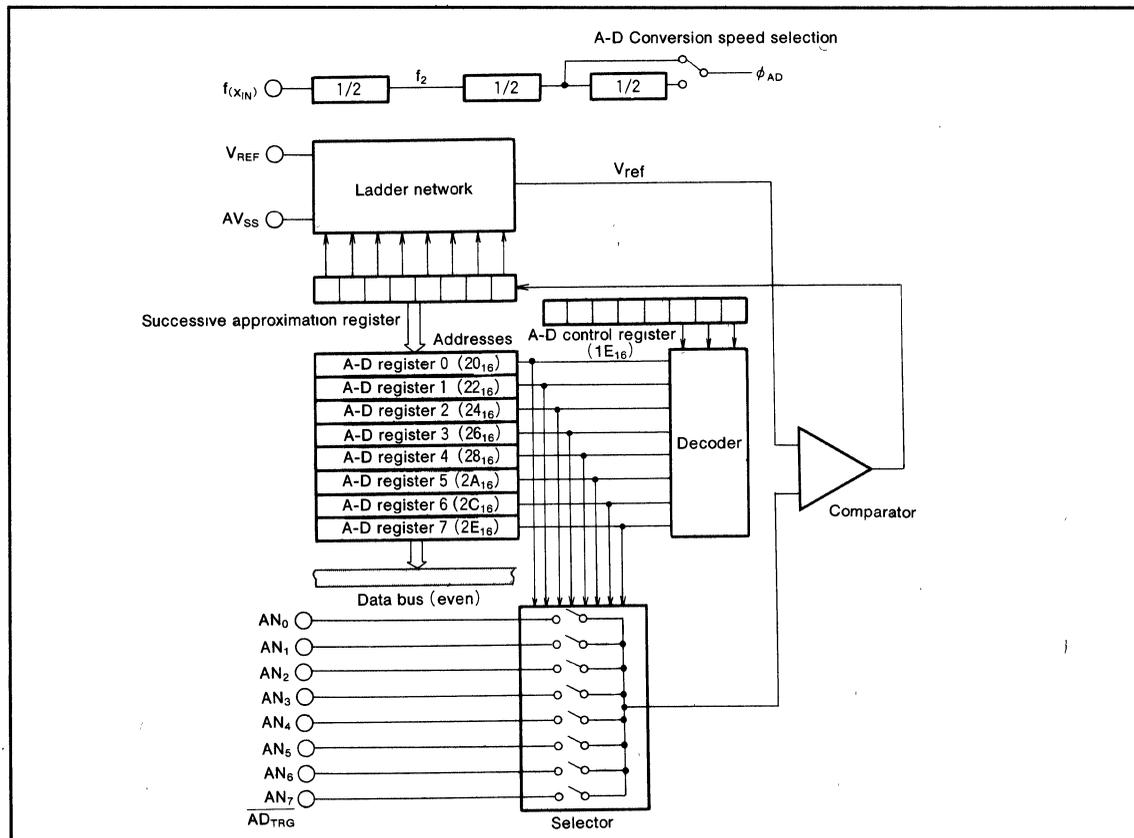

Fig. 41 A-D converter block diagram

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

WATCHDOG TIMER

The watchdog timer is used to detect unexpected execution sequence caused by software run-away.

Figure 43 shows a block diagram of the watchdog timer.

The watchdog timer consists of a 12-bit binary counter.

The watchdog timer counts the clock frequency divided by 32 (f_{32}) or by 512 (f_{512}). Whether to count f_{32} or f_{512} is determined by the watchdog timer frequency selection flag shown in Figure 44. f_{512} is selected when the flag is "0" and f_{32} is selected when it is "1". The flag is cleared after reset. FFF_{16} is set in the watchdog timer when "L" or $2V_{CC}$ is applied to the RESET pin, STP instruction is executed, data is written to the watchdog timer, or the most significant bit of the watchdog timer become "0".

After FFF_{16} is set in the watchdog timer, the contents of watchdog timer is decremented by one at every cycle of selected frequency f_{32} or f_{512} , and after 2048 counts, the most significant bit of watchdog timer become "0", and a watchdog timer interrupt request bit is set, and FFF_{16} is preset in the watchdog timer.

Normally, a program is written so that data is written in the watchdog timer before the most significant bit of the watchdog timer become "0". If this routine is not executed due to unexpected program execution, the most significant bit of the watchdog timer become eventually "0" and an interrupt is generated.

The processor can be reset by setting the bit 3 (software reset bit) of processor mode register described in Figure 10 in the interrupt section and generating a reset pulse.

The watchdog timer stops its function when the RESET pin voltage is raised to double the V_{CC} voltage.

The watchdog timer can also be used to recover from when the clock is stopped by the STP instruction. Refer to the section on clock generation circuit for more details.

The watchdog timer hold the contents during a hold state and the frequency is stopped to input.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

INPUT/OUTPUT PINS

Ports P8 to P0 all have a data direction register and each bit can be programmed for input or output. A pin becomes an output pin when the corresponding data direction register is set and an input pin when it is cleared.

When pin programmed for output, the data is written to the port latch and it is output to the output pin. When a pin is programmed for output, the contents of the port latch is read instead of the value of the pin. Therefore, a previously output value can be read correctly even when the output "L" voltage is raised due to reasons such as directly driving an LED.

A pin programmed for input is floating and the value input to the pin can be read. When a pin is programmed for input, the data is written only in the port latch and the pin stays floating.

If an input/output pin is not used as an output port, clear the bit of the corresponding data direction register so that the pin become input mode.

Figure 47 shows a block diagram of ports P8 to P0 in single-chip mode and the \bar{E} pin output.

In memory expansion mode, microprocessor mode, and evaluation chip mode, ports P4 to P0 are also used as address, data, and control signal pins.

Refer to the section on processor modes for more details.

M37700SFP, M37700SAFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

PROCESSOR MODE

The bits 0 and 1 of processor mode register as shown in Figure 48 are used to select any mode of single-chip mode, memory expansion mode, microprocessor mode, and evaluation chip mode.

Ports P3 to P0 and a part of port P4 are used as address, data, and control signal I/O pins except in single-chip mode.

Figure 49 shows the functions of ports P4 to P0 in each mode.

The external memory area changes when the mode changes.

Figure 50 shows the memory map for each mode.

Refer to Figure 1 for the memory map of the single-chip mode. The external memory area can be accessed except in single-chip mode. The accessing of the external memory is affected by the BYTE pin and the bit 2 (wait bit) of processor mode register. These will be described next.

· BYTE pin

When accessing the external memory, the level of the BYTE pin is used to determine whether to use the data bus as 8-bit width or 16-bit width.

The data bus width is 8 bits when the level of the BYTE pin is "H" and port P2 becomes the data I/O pin.

The data bus width is 16 bits when the level of the BYTE pin is "L" and ports P1 and P2 become the data I/O pins.

When accessing the internal memory, the data bus width is always 16 bits regardless of the BYTE pin level.

An exclusive mode in the evaluation chip mode allows the BYTE pin level to be set to $2 \cdot V_{CC}$. In this case, the operation is slightly different from the above. This is described in the evaluation chip mode section.

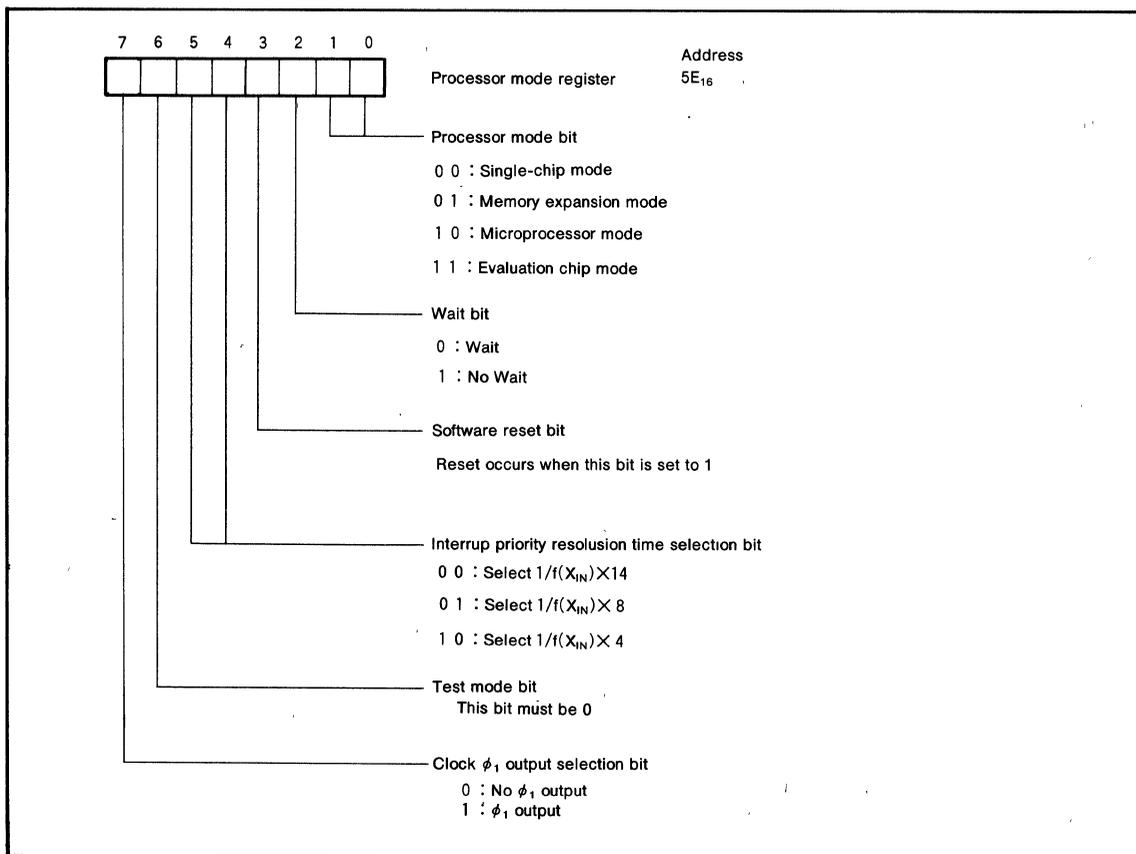

Fig.48 Processor mode register bit configuration

MITSUBISHI MICROCOMPUTERS
M37700M2-XXFP, M37700M2AXXFP
M37700SFP, M37700SAFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

· Wait bit

As shown in Figure 51, when the external memory area is accessed with the processor mode register bit 2 (wait bit) cleared to "0", the access time becomes twice the access time than the wait bit is "1" (no wait). The wait bit is cleared during reset.

The accessing of internal memory area is performed in no wait mode regardless of the wait bit.

The processor modes are described below.

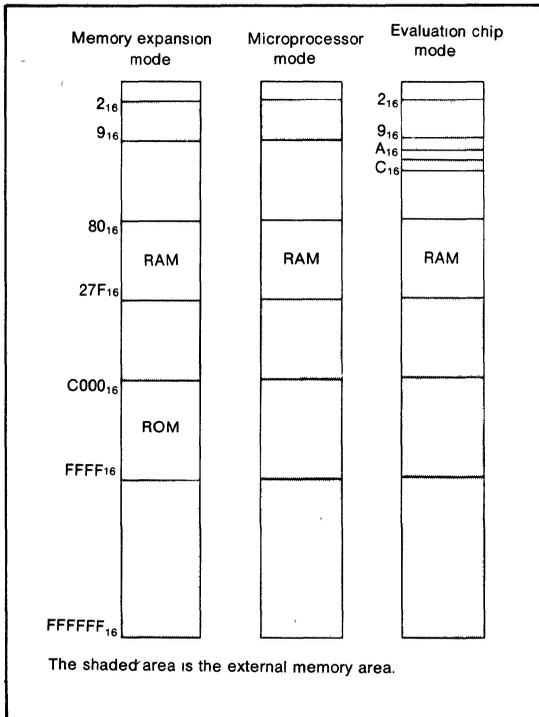

Fig.50 External memory area for each processor mode

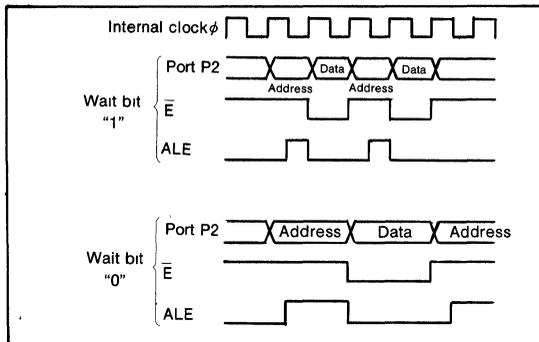

Fig.51 Relationship between wait bit and access time

(1) Single-chip mode [00]

single-chip mode is entered by connecting the CNV_{SS} pin to V_{SS} and starting from reset. Ports P4 to P0 all function as normal I/O ports.

(2) Memory expansion mode [01]

Memory expansion mode is entered by setting the processor mode bits to "01" after connecting the CNV_{SS} pin to V_{SS} and starting from reset.

Port P0 becomes an address output pin and loses its I/O port function.

Port P1 has two functions depending on the level of the BYTE pin.

When the BYTE pin level is "L", port P1 functions as an address output pin while \bar{E} is "H" and as an odd address data I/O pin while \bar{E} is "L". However, if an internal memory is read, external data is ignored while \bar{E} is "L". In this case the I/O port function is lost.

When the BYTE pin level "H", port P1 functions as an address output pin and loses its I/O port function.

Port P2 has two functions depending on the level of the BYTE pin.

When the BYTE pin level is "L", port P2 functions as an address output pin while \bar{E} is "H" and as an even address data I/O pin while \bar{E} is "L". However, if an internal memory is read, external data is ignored while \bar{E} is "L".

When the BYTE pin level is "H", port P2 functions as an address output pin while \bar{E} is "H" and as an even and odd address data I/O pin while \bar{E} is "L". However, if an internal memory is read, external data is ignored while \bar{E} is "L". In this case the I/O port function is lost.

Ports P3₀, P3₁, P3₂, and P3₃ become R/W, \overline{BHE} , ALE, and HLDA output pin respectively and lose their I/O port functions.

R/W is a read/write signal which indicates a read when it is "H" and a write when it is "L".

\overline{BHE} is a byte high enable signal which indicates that an odd address is accessed when it is "L".

Therefore, two bytes at even and odd addresses are accessed simultaneously if address A₀ is "L" and \overline{BHE} is "L".

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

CLOCK GENERATING CIRCUIT

Figure 52 shows a block diagram of the clock generator.

When an STP instruction is executed, the internal clock ϕ stops oscillating at "L" level. At the same time, FFF_{16} is written to watchdog timer and the watchdog timer input connection is forced to f_{32} . This connection is broken and connected to the input determined by the watchdog timer frequency selection flag when the most significant bit of the watchdog timer is cleared or reset.

Oscillation resumes when an interrupt is received, but the internal clock ϕ remains at "L" level until the most significant bit of the watchdog timer is cleared. This is to avoid the unstable interval at the start of oscillation when using a ceramic resonator.

When a WIT instruction is executed, the internal clock ϕ stops at "L" level, but the oscillator does not stop. The clock is restarted when an interrupt is received. Instructions can be executed immediately because the oscillator is not stopped.

The stop or wait state is released when an interrupt is received or when reset is issued. Therefore, interrupts must be enabled before executing a STP or WIT instruction.

Figure 53 shows a circuit example using a ceramic (or quartz crystal) resonator. Use the manufacturer's recommended values for constants such as capacitance which differ for each resonator. Figure 54 shows an example of using an external clock signal.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

DESCRIPTION

The M37701M2-XXXSP, M37701M2AXXSP, M37701SSP and M37701SASP are single-chip microcomputers designed with high-performance CMOS silicon gate technology. These are housed in a 64-pin shrink plastic molded DIP. These single-chip microcomputers have a large 16M bytes address space, three instruction queue buffers, and two data buffers for high-speed instruction execution. The CPU is a 16-bit parallel processor that can also be switched to perform 8-bit parallel processing. These microcomputers are suitable for office, business and industrial equipment controller that require high-speed processing of large data.

The differences between M37701M2-XXXSP, M37701M2AXXSP, M37701SSP and M37701SASP are the ROM size and the external clock input frequency as shown below. Therefore, the following descriptions will be for the M37701M2-XXXSP unless otherwise noted.

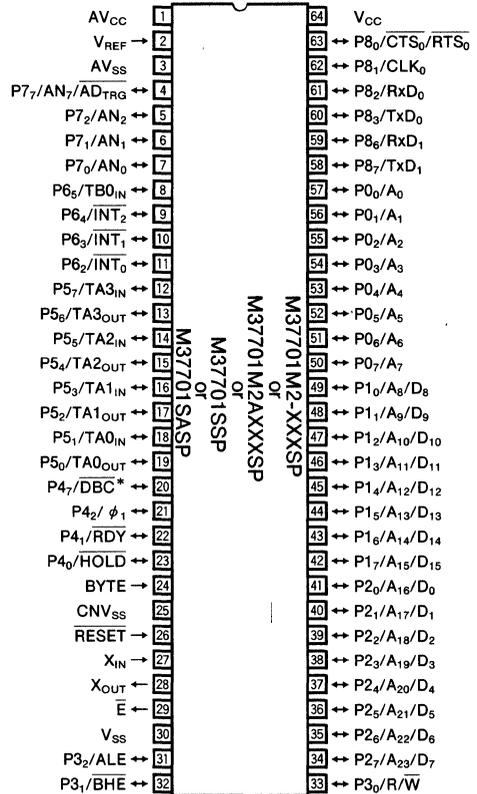

Type name	ROM size	External clock input frequency
M37701M2-XXXSP	16K bytes	8 MHz
M37701M2AXXSP	16K bytes	16MHz
M37701SSP	External	8 MHz
M37701SASP	External	16MHz

The M37701M2-XXXSP cuts down the pins of M37700M2-XXXFP. Refer to the section on M37700M2-XXXFP for the functional differences.

DISTINCTIVE FEATURES

- Number of basic instructions..... 103
- Memory size ROM.....16K bytes
 RAM.....512 bytes
- Instruction execution time
M37701M2-XXXSP, M37701SSP
(The fastest instruction at 8 MHz frequency)..... 500ns
M37701M2AXXSP, M37701SASP
(The fastest instruction at 16 MHz frequency)..... 250ns
- Single power supply.....5V±10%
- Low power dissipation (at 8 MHz frequency)
..... 30mW (Typ.)
- Interrupts..... 19 types 7 levels
- Multiple function 16-bit timer..... 5+3
- UART (may also be synchronous)..... 2
- 8-bit A-D converter..... 4-channel inputs
- 12-bit watchdog timer
- Programmable input/output
(ports P0, P1, P2, P3, P4, P5, P6, P7, P8)..... 53

PIN CONFIGURATION (TOP VIEW)

Outline 64P4B

* Used in the evaluation chip mode only

APPLICATION

Control devices for office equipment such as copiers, printers, typewriters, facsimiles, word processors, and personal computers

Control devices for industrial equipment such as ME, NC, communication, and measuring instruments

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

FUNCTIONS OF M37701M2-XXXSP

Parameter		Functions
Number of basic instructions		103
Instruction execution time	M37701M2-XXXSP, M37701SSP	500ns (the fastest instructions, at 8MHz frequency)
	M37701M2AXXSP, M37701SASP	250ns (the fastest instructions, at 16MHz frequency)
Memory size	ROM	16K bytes
	RAM	512 bytes
Input/Output ports	P0, P1, P2, P5	8-bitX 4
	P8	6-bitX 1
	P4, P6, P7	4-bitX 3
	P3	3-bitX 1
Multi-function timers	TA0, TA1, TA2, TA3, TA4	16-bitX 5 (4 Input/Output functions)
	TB0, TB1, TB2	16-bitX 3 (1 Input function)
Serial I/O		UARTX2(One can be set clock synchronous serial I/O)
A-D converter		8-bitX 1 (4 channels)
Watchdog timer		12-bitX 1
Interrupts		3 external types, 16 internal types (Each interrupt can be set the priority levels to 0~7)
Clock generating circuit		Built-in(externally connected to a ceramic resonator or quartz crystal resonator)
Supply voltage		5 V±10%
Power dissipation		30mW(at external 8 MHz frequency)
Input/Output characteristic	Input/Output voltage	5 V
	Output current	5 mA
Memory expansion		Maximum 16M bytes
Operating temperature range		-10~70°C
Device structure		CMOS high-performance silicon gate process
Package		64-pin shrink plastic molded DIP

M37701SSP, M37701SASP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

BASIC FUNCTION BLOCKS

The functional differences between the M7701M2-XXXSP and M37700M2-XXXFP are described below. The M37701M2-XXXSP has the same functions as the M37700M2-XXXFP, except these points. Refer to the section on the M37700M2-XXXFP.

A-D CONVERTER

Analog signals are input through four channels, AN₀, AN₁, AN₂ and AN₇. In one-shot mode and repeat mode, select one on AN₀, AN₁, AN₂, and AN₇ as analog input by the analog input selection bits (bits 2, 1 and 0) of A-D control register. Set the bits of the directional registers for ports corresponding to analog input channels AN₃, AN₄, AN₅ and AN₆ not having pins to "1" (output mode) and output "0" to the ports.

In the single sweep mode and repeat sweep mode, the M37701M2-XXXSP operates the same as the M37700M2-XXXFP. Set the directional register bits of ports corresponding to AN₀, AN₁, AN₂, and AN₇ to "0" (input mode), and the bits of the directional registers for ports corresponding to AN₃, AN₄, AN₅ and AN₆ not having pins to "1" (output mode), and output "0" to the ports. In the single sweep mode and repeat sweep mode, the contents of A-D register bits corresponding to analog input channels AN₃, AN₄, AN₅, and AN₆ not having pins are undefined.

TIMER

Since timer A4 has no input/output function and timer B1, B2 have no input function, timers A4, B1 and B2 operate only in timer mode. Therefore, only clock source can be selected by the bits 7 and 6 of timer mode register for each of timers A4, B1 and B2. The bits of timer mode register must be "0" except for the clock source selection bits. Other timers A0, A1, A2, A3 and B0 have the same functions as the M37700M2-XXXFP.

SERIAL I/O

UART1 has only the asynchronous serial communication function and no clock synchronous serial communication function. Therefore, do not select the clock synchronous serial communication function ("001") by the serial communication method selection bits (bits 2, 1 and 0) of UART1 transmit/receive mode register. Since UART1 does not have the functions of CTS and RTS, the CTS and RTS selection bit (bit 2) of UART1 transmit/receive control register 0 must always be "1". UART0 has the same function as the M37700M2-XXXFP.

INPUT/OUTPUT PINS

The port registers and directional registers for ports P4, P6, P7 and P8 have eighth bits, the directional register bits having no pins must always be set to the output mode. Since port P3₃ is not available as a pin although it has port register and directional register, port P3₃ must be set to the output mode.

ADDRESSING MODES

The M37701M2-XXXSP has 28 powerful addressing modes. Refer to the Series MELPS 7700 addressing mode description for the details of each addressing mode.

MACHINE INSTRUCTION LIST

The M37701M2-XXXSP has 103 machine instructions. Refer to the Series MELPS 7700 machine instruction list for details.

DATA REQUIRED FOR MASK ORDERING

Please send the following data for mask orders.

- (1) M37701M2-XXXSP mask ROM order confirmation form
- (2) Mark specification form for 64P4B
- (3) ROM data (EPROM 3 sets)

Table 1. The functional differences between the M37701M2-XXXSP and M37700M2-XXXFP

Parameter	M37701M2-XXXSP	M37700M2-XXXFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

DESCRIPTION

The M37701M4-XXXSP, M37701M4AXXSP, M37701S4SP and M37701S4ASP are single-chip microcomputers designed with high-performance CMOS silicon gate technology. These are housed in a 64-pin shrink plastic molded DIP. These single-chip microcomputers have a large 16M bytes address space, three instruction queue buffers, and two data buffers for high-speed instruction execution. The CPU is a 16-bit parallel processor that can also be switched to perform 8-bit parallel processing. These microcomputers are suitable for office, business and industrial equipment controller that require high-speed processing of large data.

The differences between M37701M4-XXXSP, M37701M4AXXSP, M37701S4SP and M37701S4ASP are the ROM size and the external clock input frequency as shown below. Therefore, the following descriptions will be for the M37701M4-XXXSP unless otherwise noted.

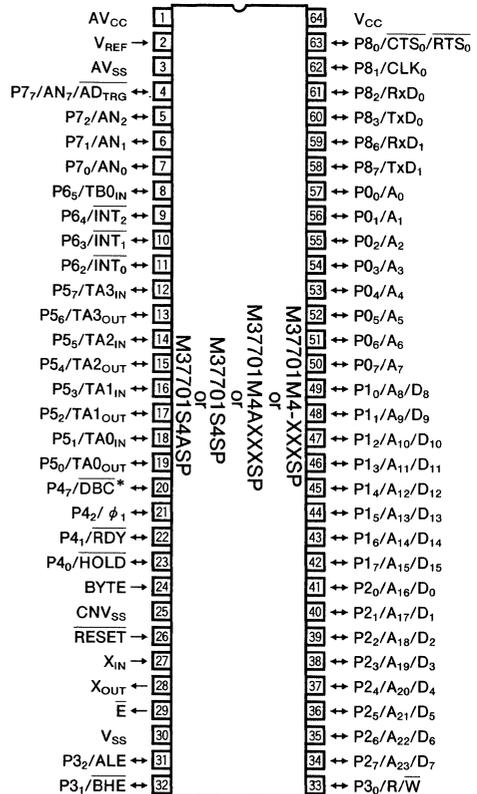

Type name	ROM size	External clock input frequency
M37701M4-XXXSP	32K bytes	8 MHz
M37701M4AXXSP	32K bytes	16MHz
M37701S4SP	External	8 MHz
M37701S4ASP	External	16MHz

The M37701M4-XXXSP has the same functions as the M37701M2-XXXSP except for the memory size.

DISTINCTIVE FEATURES

- Number of basic instructions.....103
- Memory size ROM32K bytes
RAM..... 2048 bytes
- Instruction execution time
M37701M4-XXXSP, M37701S4SP
(The fastest instruction at 8 MHz frequency) 500ns
M37701M4AXXSP, M37701S4ASP
(The fastest instruction at 16 MHz frequency)..... 250ns
- Single power supply5V±10%
- Low power dissipation (at 8 MHz frequency)
..... 30mW (Typ.)
- Interrupts 19 types 7 levels
- Multiple function 16-bit timer 5+3
- UART (may also be synchronous) 2
- 8-bit A-D converter 4-channel inputs
- 12-bit watchdog timer
- Programmable input/output
(ports P0, P1, P2, P3, P4, P5, P6, P7, P8) 53

PIN CONFIGURATION (TOP VIEW)

Outline 64P4B

* Used in the evaluation chip mode only

APPLICATION

Control devices for office equipment such as copiers, printers, typewriters, facsimiles, word processors, and personal computers

Control devices for industrial equipment such as ME, NC, communication, and measuring instruments

THE FUNCTIONS AND CHARACTERISTICS

The M37701M4-XXXSP has the same functions and characteristics as the M37701M2-XXXSP except for the ROM and RAM size. Refer to the section on the M37701M2-XXXSP.

DATA REQUIRED FOR MASK ORDERING

Please send the following data for mask orders.

- (1) M37701M4-XXXSP mask ROM order confirmation form
- (2) Mark specification form for 64P4B
- (3) ROM data (EPROM 3 sets)

M37704M2-XXXFP, M37704M2AXXFP M37704S1FP, M37704S1AFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

DESCRIPTION

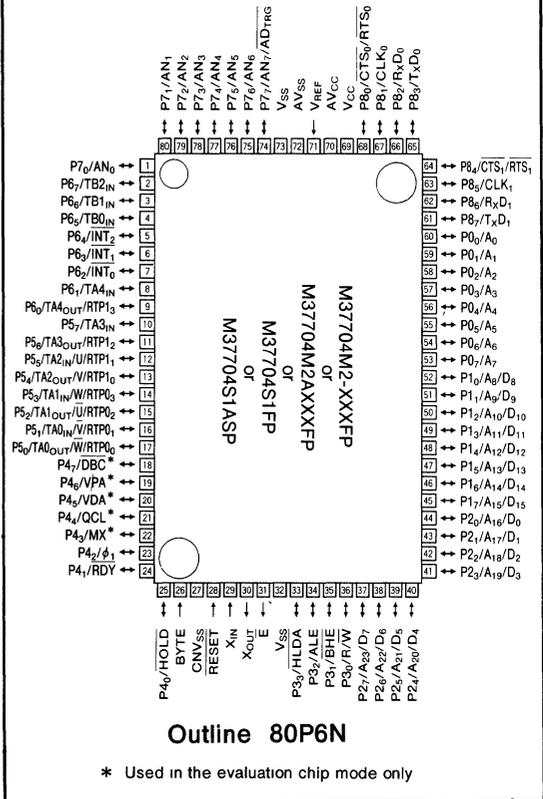

The M37704M2-XXXFP, M37704M2AXXFP, M37704S1FP and M37704S1AFP are single-chip microcomputers designed with high-performance CMOS silicon gate technology. These are housed in a 80-pin plastic molded QFP. These single-chip microcomputers have a large 16M bytes address space, three instruction queue buffers, and two data buffers for high-speed instruction execution. The CPU is a 16-bit parallel processor that can also be switched to perform 8-bit parallel processing. These microcomputers are suitable for office, business, and industrial equipment controller that require high-speed processing of large data. Also, the incorporated motor control circuit makes these microcomputers suitable for control of equipment that requires motor control. The differences between M37704M2-XXXFP, M37704M2AXXFP, M37704S1FP and M37704S1AFP are the ROM size and the external clock input frequency as shown below. Therefore, the following descriptions will be for the M37704M2-XXXFP unless otherwise noted.

Type name	ROM size	External clock input frequency
M37704M2-XXXFP	16K bytes	8 MHz
M37704M2AXXFP	16K bytes	16MHz
M37704S1FP	External	8 MHz
M37704S1AFP	External	16MHz

DISTINCTIVE FEATURES

- Number of basic instructions.....103
- Memory size ROM.....16K bytes
RAM.....512 bytes
- Instruction execution time
M37704M2-XXXFP, M37704S1FP
(The fastest instruction at 8 MHz frequency).....500ns
M37704M2AXXFP, M37704S1AFP
(The fastest instruction at 16 MHz frequency).....250ns
- Single power supply.....5V±10%
- Low power dissipation (at 8 MHz frequency)
.....30mW (Typ.)
- Interrupts.....19 types 7 levels
- Multiple function 16-bit timer.....5+3
(Three-phase motor drive waveform or pulse motor drive waveform can be output.)
- UART (may also be synchronous).....2
- 8-bit A-D converter.....8-channel inputs
- 12-bit watchdog timer
- Programmable input/output
(ports P0, P1, P2, P3, P4, P5, P6, P7, P8).....68

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

BASIC FUNCTION BLOCKS

The M37704M2-XXXFP contains the following devices on a single chip: ROM and RAM for storing instructions and data, CPU for processing, bus interface unit (which controls instruction prefetch and data read/write between CPU and memory), timers, UART, A-D converter, and other peripheral devices such as I/O ports. Each of these devices are described below.

MEMORY

The memory map is shown in Figure 1. The address space is 16M bytes from addresses 0_{16} to $FFFFFF_{16}$. The address space is divided into 64K bytes units called banks. The banks are numbered from 0_{16} to FF_{16} .

Built-in ROM, RAM and control registers for built-in peripheral devices are assigned to bank 0.

The 16K bytes area from addresses $C000_{16}$ to $FFFF_{16}$ is the built-in ROM. Addresses $FFD6_{16}$ to $FFFF_{16}$ are the RESET and interrupt vector addresses and contain the interrupt vectors. Refer to the section on interrupts for details.

The 512 bytes area from addresses 80_{16} to $27F_{16}$ contains the built-in RAM. In addition to storing data, the RAM is used as stack during a subroutine call, or interrupts.

Assigned to addresses 0_{16} to $7F_{16}$ are peripheral devices such as I/O ports, A-D converter, UART, timer, and interrupt control registers.

A 256 bytes direct page area can be allocated anywhere in bank 0 using the direct page register DPR. In direct page addressing mode, the memory in the direct page area can be accessed with two words thus reducing program steps.

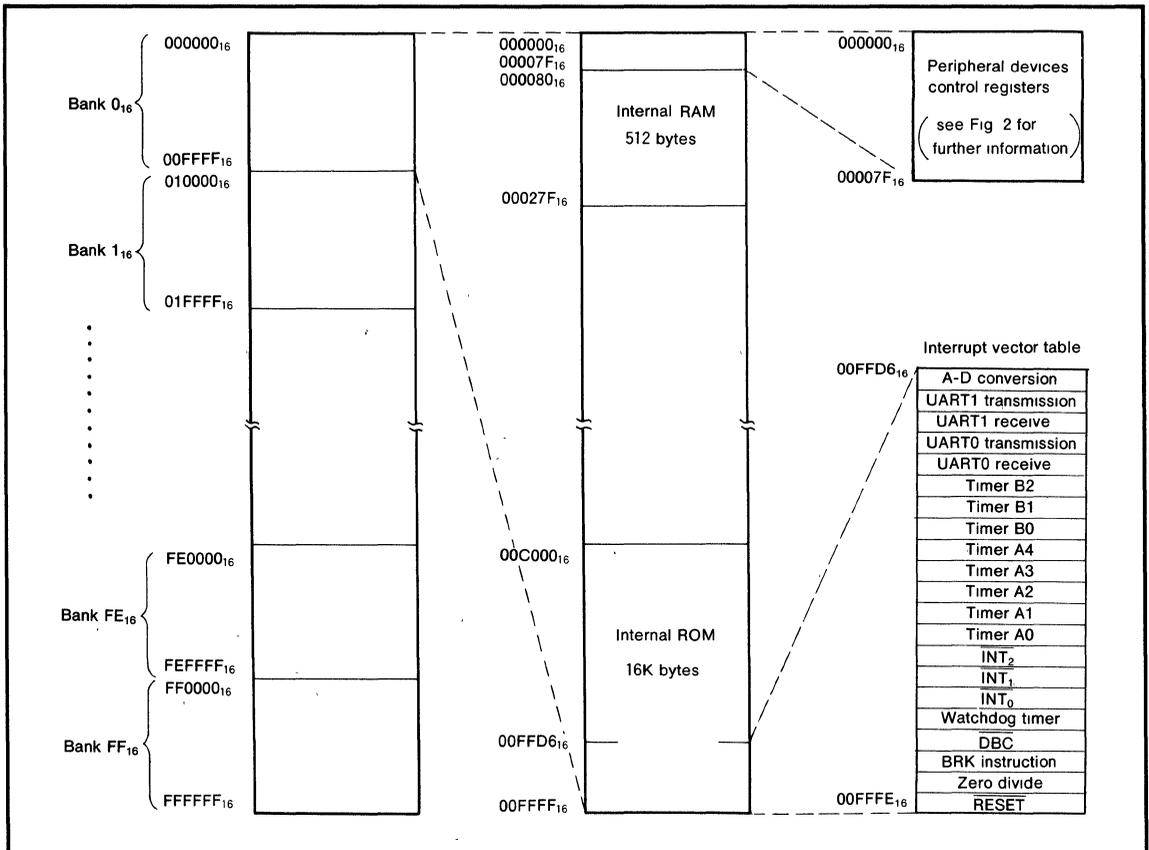

Fig. 1 Memory map

M37704S1FP, M37704S1AFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

CENTRAL PROCESSING UNIT (CPU)

The CPU has ten registers and is shown in Figure 3. Each of these registers is described below.

ACCUMULATOR A (A)

Accumulator A is the main register of the microcomputer. It consists of 16 bits and the lower 8 bits can be used separately. The data length flag *m* determines whether the register is used as 16-bit register or as 8-bit register. It is used as a 16-bit register when flag *m* is "0" and as an 8-bit register when flag *m* is "1". Flag *m* is a part of the processor status register (PS) which is described later.

Data operations such as calculations, data transfer, input/output, etc., is executed mainly through the accumulator.

ACCUMULATOR B (B)

Accumulator B has the same functions as accumulator A, but the use of accumulator B requires more instruction bytes and execution cycles than accumulator A.

INDEX REGISTER X (X)

Index register X consists of 16 bits and the lower 8 bits can be used separately. The index register length flag *x* determines whether the register is used as 16-bit register or as 8-bit register. It is used as a 16-bit register when flag *x* is "0" and as an 8-bit register when flag *x* is "1". Flag *x* is a part of the processor status register (PS) which is described later.

In index addressing mode, register X is used as the index register and the contents of this address is added to obtain the real address.

Also, when executing a block transfer instruction MVP or MVN, the contents of index register X indicates the low-order 16 bits of the source data address. The third byte of the MVP and MVN is the high-order 8 bits of the source data address.

INDEX REGISTER Y (Y)

Index register Y consists of 16 bits and the lower 8 bits can be used separately. The index register length flag *x* determines whether the register is used as 16-bit register or as 8-bit register. It is used as a 16-bit register when flag *x* is "0" and as an 8-bit register when flag *x* is "1". Flag *x* is a part of the processor status register (PS) which is described later.

In index addressing mode, register Y is used as the index register and the contents of this address is added to obtain the real address.

Also, when executing a block transfer instruction MVP or MVN, the content of index register Y indicates the low-order 16 bits of the destination address. The second byte of the MVP and MVN is the high-order 8 bits of the destination data address.

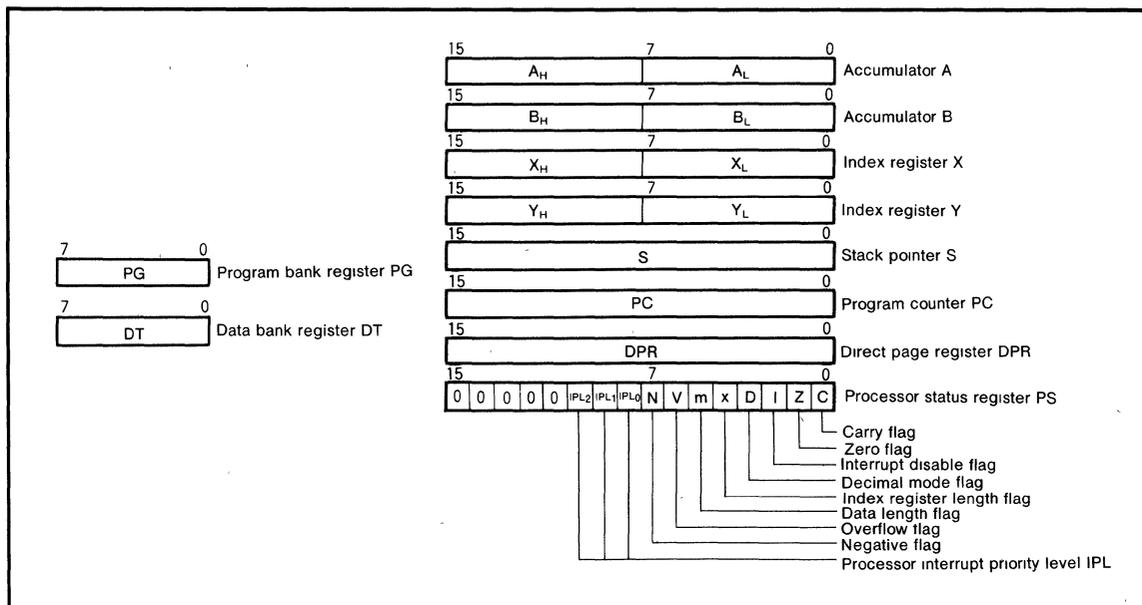

Fig. 3 Register structure

MITSUBISHI MICROCOMPUTERS
M37704M2-XXFP, M37704M2AXXFP
M37704S1FP, M37704S1AFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

5. Index register length flag (x)

The index register length flag determines whether index register X and index register Y are used as 16-bit registers or as 8-bit registers. The registers are used as 16-bit registers when flag x is "0" and as 8-bit registers when it is "1". This flag can be set and reset with the SEP and CLP instructions.

6. Data length flag (m)

The data length flag determines whether the data length is 16-bit or 8-bit. The data length is 16-bit when flag m is "0" and 8-bit when it is "1". This flag can be set and reset with the SEM and CLM instructions or with the SEP and CLP instructions.

7. Overflow flag (V)

The overflow flag has meaning when addition or subtraction is performed a word as signed binary number. When the data length flag m is "0", the overflow flag is set when the result of addition or subtraction is outside the range between -32768 and +32767. When the data length flag m is "1", the overflow flag is set when the result of addition or subtraction is outside the range between -128 and +127. It is reset in all other cases. The overflow flag can also be set and reset directly with the SEP, and CLV or CLP instructions.

8. Negative flag (N)

The negative flag is set when the result of arithmetic operation or data transfer is negative (If data length flag m is "0", when data bit 15 is "1". If data length flag m is "1", when data bit 7 is "1".) It is reset in all other cases. It can also be set and reset with the SEP and CLP instructions.

9. Processor interrupt priority level (IPL)

The processor interrupt priority level (IPL) consists of 3 bits and determines the priority of processor interrupts from level 0 to level 7. Interrupt is enabled when the interrupt priority of the device requesting interrupt (set using the interrupt control register) is higher than the processor interrupt priority. When interrupt is enabled, the current processor interrupt priority level is saved in a stack and the processor interrupt priority level is replaced by the interrupt priority level of the device requesting the interrupt. Refer to the section on interrupts for more details.

BUS INTERFACE UNIT

The CPU operates on an internal clock frequency which is obtained by dividing the external clock frequency $f_{(XIN)}$ by two. This frequency is twice the bus cycle frequency. In order to speed-up processing, a bus interface unit is used to pre-fetch instructions when the data bus is idle. The bus interface unit synchronizes the CPU and the bus and pre-fetches instructions. Figure 4 shows the relationship between the CPU and the bus interface unit. The bus interface unit has a program address register, a 3-byte instruction queue buffer, a data address register, and a 2-byte data buffer.

The bus interface unit obtains an instruction code from memory and stores it in the instruction queue buffer, obtains data from memory and stores it in the data buffer, or writes the data from the data buffer to the memory.

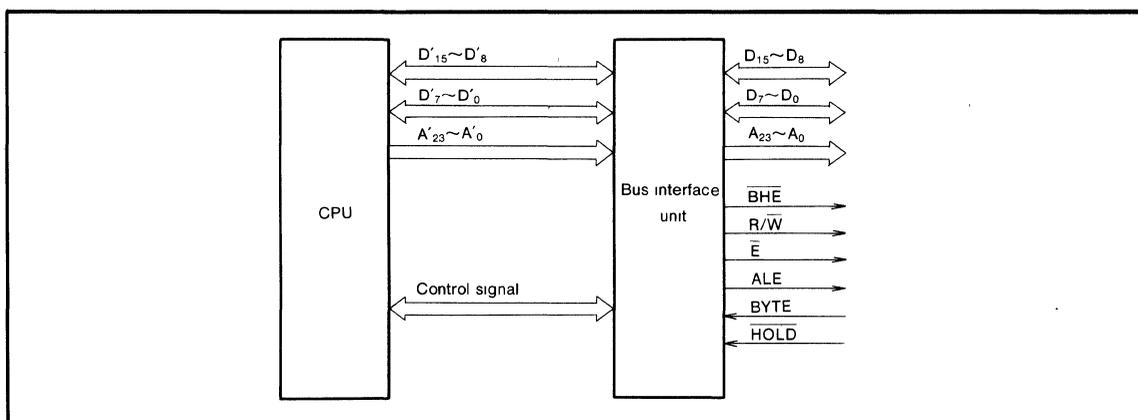

Fig. 4 Relationship between the CPU and the bus interface unit

MITSUBISHI MICROCOMPUTERS
M37704M2-XXXXFP, M37704M2AXXXFP
M37704S1FP, M37704S1AFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

Instruction code read will be described first.

The CPU obtains instruction codes from the instruction queue buffer and executes them. The CPU notifies the bus interface unit that it is requesting an instruction code during an instruction code request cycle. If the requested instruction code is not yet stored in the instruction queue buffer, the bus interface unit halts the CPU until it can store more instructions than requested in the instruction queue buffer.

Even if there is no instruction code request from the CPU, the bus interface unit reads instruction codes from memory and stores them in the instruction queue buffer when the instruction queue buffer is empty or when only one instruction code is stored and the bus is idle on the next cycle.

This is referred to as instruction pre-fetching.

Normally, when reading an instruction code from memory, if the accessed address is even the next odd address is read together with the instruction code and stored in the instruction queue buffer.

However, in memory expansion mode or microprocessor mode, if the bus width switching pin BYTE is "H", external data bus width is 8 bits and the address to be read is in external memory area is odd, only one byte is read and stored in the instruction queue buffer. Therefore, waveform (1) or (3) in Figure 5 is used for instruction code read.

Data read and write are described below.

The CPU notifies the bus interface unit when performing data read or write. At this time, the bus interface unit halts the CPU if the bus interface unit is already using the bus or if there is a request with higher priority. When data read or write is enabled, the bus interface unit uses one of the waveforms from (1) to (6) in Figure 5 to perform the operation.

During data read, the CPU waits until the entire data is stored in the data buffer. The bus interface unit sends the address received from the CPU to the address bus. Then it reads the memory when the \bar{E} signal is "L" and stores the result in the data buffer.

During data write, the CPU writes the data in the data buffer and the bus interface unit writes it to memory. Therefore, the CPU can proceed to the next step without waiting for write to complete. The bus interface unit sends the address received from the CPU to the address bus. Then when the \bar{E} signal is "L", the bus interface unit sends the data in the data buffer to the data bus and writes it to memory.

INT ₀ interrupt control register	00007D ₁₆
INT ₁ interrupt control register	00007E ₁₆
INT ₂ interrupt control register	00007F ₁₆

Interrupts caused by a BRK instruction and when dividing by zero are software interrupts and are not included in this list.

Other interrupts previously mentioned are A-D converter, UART, Timer, INT interrupts. The priority of these interrupts can be changed by changing the priority level in the corresponding interrupt control register by software.

Figure 8 shows a diagram of the interrupt priority resolution circuit. When an interrupt is caused, the each interrupt device compares its own priority with the priority from above and if its own priority is higher, then it sends the priority below and requests the interrupt. If the priorities are the same, the one above has priority.

This comparison is repeated to select the interrupt with the highest priority among the interrupts that are being requested. Finally the selected interrupt is compared with the processor interrupt priority level (IPL) contained in the processor status register (PS) and the request is accepted if it is higher than IPL and the interrupt disable flag I is "0". The request is not accepted if flag I is "1". The reset, DBC, and watchdog timer interrupts are not affected by the interrupt disable flag I.

When an interrupt is accepted, the contents of the processor status register (PS) is saved to the stack and the interrupt disable flag I is set to "1".

Furthermore, the interrupt request bit of the accepted interrupt is cleared to "0" and the processor interrupt priority level (IPL) in the processor status register (PS) is replaced by the priority level of the accepted interrupt.

Therefore, multi-level priority interrupts are possible by resetting the interrupt disable flag I to "0" and enable further interrupts.

For reset, DBC, watchdog timer, zero divide, and BRK instruction interrupts, which do not have an interrupt control register, the processor interrupt level (IPL) is set as shown in Table 3.

Priority resolution is performed by latching the interrupt request bit and interrupt priority level so that they do not change. They are sampled at the first half and latched at the last half of the operation code fetch cycle.

Because priority resolution takes some time, no sampling pulse is generated for a certain interval even if it is the next operation code fetch cycle.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

TIMER

There are eight 16-bit timers. They are divided by type into timer A(5) and timer B(3).

The timer I/O pins are shared with I/O pins for port P5 and P6. To use these pins as timer input pins, the data direction register bit corresponding to the pin must be cleared to "0" to specify input mode.

Using this timer, confirm the function as this timer is different a little from M37700M2-XXXFP's.

TIMER A

Figure 11 shows a block diagram of timer A.

Timer A has four modes; timer mode, event counter mode, one-shot pulse mode, and pulse width modulation mode. The mode is selected with bits 0 and 1 of the timer Ai mode register ($i = 0$ to 4). Each of these modes is described below.

(1) Timer mode (00)

Figure 12 shows the bit configuration of the timer Ai mode register during timer mode. Bits 0, 1, and 5 of the timer Ai mode register must always be "0" in timer mode.

Bit 3 is ignored if bit 4 is "0".

Bits 6 and 7 are used to select the timer counter source. The counting of the selected clock starts when the count start flag is "1" and stops when it is "0".

Figure 13 shows the bit configuration of the count start flag. The counter is decremented, an interrupt is caused and the interrupt request bit in the timer Ai interrupt control register is set when the contents becomes 0000_{16} . At the same time, the contents of the reload register is transferred to the counter and count is continued.

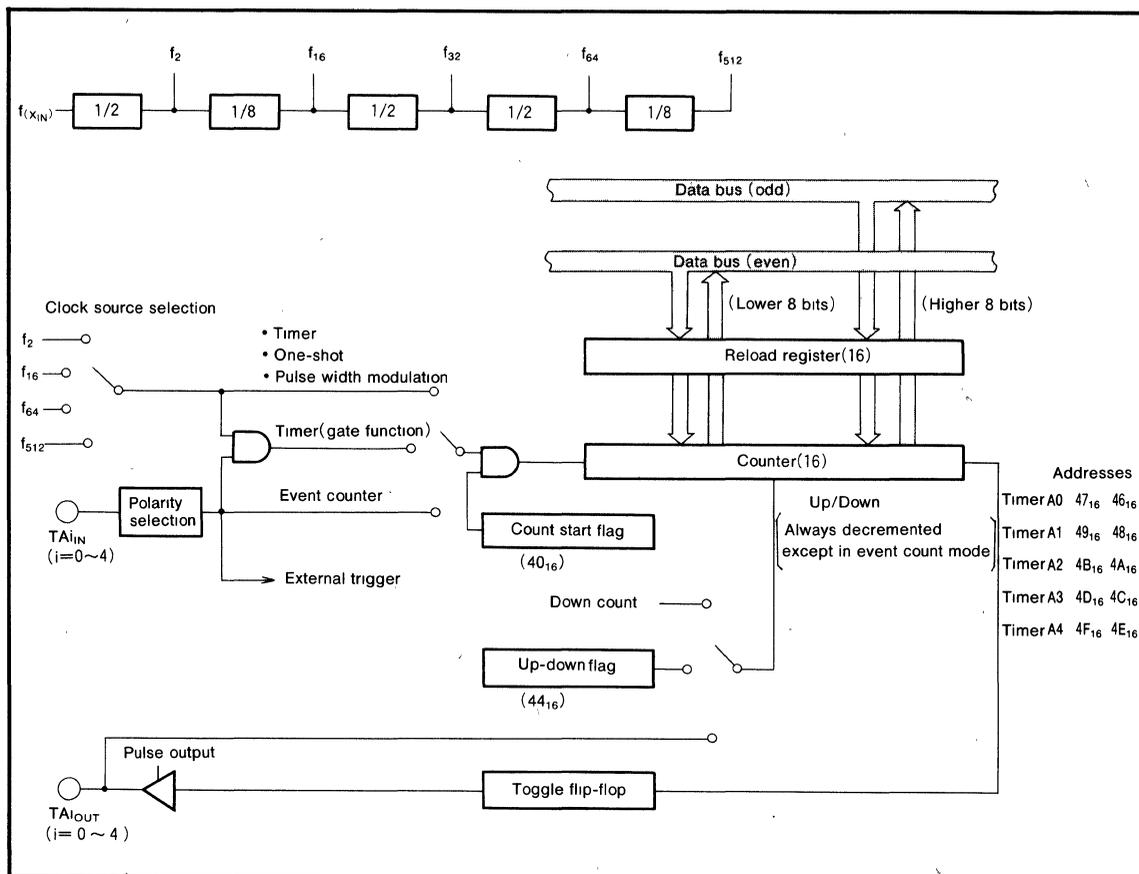

Fig. 11 Block diagram of timer A

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

Data write and data read are performed in the same way as for timer mode. That is, when data is written to timer A_i halted, it is also written to the reload register and the counter. When data is written to timer A_i which is busy, the data is written to the reload register, but not to the counter. The counter is reloaded with new data from the reload register at the next reload time. The counter can be read at any time.

In event counter mode, whether to increment or decrement the counter can also be determined by supplying two-phase pulse input with phase shifted by 90° to timer A2, A3, or A4. There are two types of two-phase pulse processing operations. One uses timers A2 and A3, and the other uses timer A4. In either processing operation, two-phase pulse is input in the same way, that is, pulses out of phase by 90° are input at the TA_{jOUT} ($j=2$ to 4) pin and TA_{jIN} pin.

When timers A2 and A3 are used, as shown in Figure 17, the count is incremented when a rising edge is input to the TA_{kIN} pin after the level of TA_{kOUT} ($k=2, 3$) pin changes from "L" to "H", and when the falling edge is inserted, the count is decremented.

For timer A4, as shown in Figure 18, when a phase related pulse with a rising edge input to the TA_{4IN} pin is input after the level of TA_{4OUT} pin changes from "L" to "H", the count is incremented at the respective rising edge and falling edge of the TA_{4OUT} pin and TA_{4IN} pin.

When a phase related pulse with a falling edge input to the TA_{4OUT} pin is input after the level of TA_{4IN} pin changes from "H" to "L", the count is decremented at the respective rising edge and falling edge of the TA_{4IN} pin and TA_{4OUT} pin. When performing this two-phase pulse signal proces-

sing, timer A_j mode register bit 0 and bit 4 must be set to "1" and bits 1, 2, 3, and 5 must be "0". Bits 6 and 7 are ignored. Note that bits 5, 6, and 7 of the up-down flag register (44_{16}) are the two-phase pulse signal processing selection bit for timer A2, A3, and A4 respectively. Each timer operates in normal event counter mode when the corresponding bit is "0" and performs two-phase pulse signal processing when it is "1".

Count is started by setting the count start flag to "1". Data write and read are performed in the same way as for normal event counter mode. Note that the direction register of the input port must be set to input mode because two-phase pulse signal is input. Also, there can be no pulse output in this mode.

Therefore, if the low order 8-bit of the reload register is n , the period of the generated pulse is

$$\frac{1}{\text{selected clock frequency}} \times (n+1).$$

The high order 8-bit function as an 8-bit length pulse width modulator using this pulse as input. The operation is the same as for 16-bit length pulse width modulator except that

the length is 8 bits. If the high order 8-bit of the reload register is m , the duration "H" of pulse is

$$\frac{1}{\text{selected clock frequency}} \times (n+1) \times m.$$

And the output pulse period is

$$\frac{1}{\text{selected clock frequency}} \times (n+1) \times (2^8-1).$$

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

(2) Event counter mode (01)

Figure 29 shows the bit configuration of the timer Bi mode register during event counter mode. In event counter mode, the bit 0 in the timer Bi mode register must be "1" and bit 1 must be "0".

The input signal from the TBi_{IN} pin is counted when the count start flag is "1" and counting is stopped when it is "0". Count is performed at the fall of the input signal when bits 2, and 3 are "0" and at the rise of the input signal when bit 3 is "0" and bit 2 is "1".

When bit 3 is "1" and bit 2 is "0", count is performed at the rise and fall of the input signal.

Data write, data read and timer interrupt are performed in the same way as for timer mode.

(3) Pulse period measurement/pulse width measurement mode (10)

Figure 30 shows the bit configuration of the timer Bi mode register during pulse period measurement/pulse width measurement mode.

In pulse period measurement/pulse width measurement mode, bit 0 must be "0" and bit 1 must be "1". Bits 6 and 7 are used to select the clock source. The selected clock is counted when the count start flag is "1" and counting stops when it is "0".

The pulse period measurement mode is selected when bit 3 is "0". In pulse period measurement mode, the selected clock is counted during the interval starting at the fall of the input signal from the TBi_{IN} pin to the next fall or at the rise of the input signal to the next rise and the result is stored in the reload register. In this case, the reload register acts as a buffer register.

When bit 2 is "0", the clock is counted from the fall of the input signal to the next fall. When bit 2 is "1", the clock is counted from the rise of the input signal to the next rise.

In the case of counting from the fall of the input signal to the next fall, counting is performed as follows. As shown in Figure 31, when the fall of the input signal from TBi_{IN} pin is detected, the contents of the counter is transferred to the reload register. Next the counter is cleared and count is started from the next clock. When the fall of the next input signal is detected, the contents of the counter is transferred to the reload register once more, the counter is cleared, and the count is started. The period from the fall of the input signal to the next fall is measured in this way.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

Timer B can detect phase difference by using timer B1 and timer B0. The phase detection mode is explained below. Figure 33 shows a block diagram of the phase detection mode. In the phase detection mode, timer B1 and timer B0 are used. Set timer B1 to the timer mode and timer B0 to the pulse period measurement/pulse width measurement mode. For selection of the phase detection mode, set bit 4 of the timer B0 mode register (5B₁₆ address) to "1". Bit 5 of timer B0 mode register functions as phase detection flag by setting bit 4 to "1". Figure 34 shows the bit configuration of the timer B0 mode register and the timer B1 mode register in the phase detection mode.

Figure 35 shows an example of operation in the phase detection mode. First, each time the counter of timer B1 is set to 0000₁₆ in the timer mode of timer B1, a signal reversing polarity is generated as a reference signal. Next an external signal is input from the TB0_{IN} pin. By setting bit 4 of the timer B0 mode register to "1", timer B0 measures the pulse width of the logical sum (AND) signal of the reference signal generated from timer B1 and the external input signal from the TB0_{IN} pin. The bit 5 (phase detection flag) of the timer B0 mode register indicates whether the phase of the signal from the TB0_{IN} pin is ahead or behind with respect to the reference signal. The phase detection flag gets the input level from the TB0_{IN} pin at the rising from "L" to "H" of the reference signal. "0" of phase detection flag indicates that the phase of the input signal from the TB0_{IN} pin is behind with respect to the reference signal. "1" indicates that the phase of the input signal from the TB0_{IN} pin is ahead with respect to the reference signal.

To detect the phase difference between the reference signal and the input signal of the TB0_{IN} pin, advance the phase of the input signal from the TB0_{IN} pin with respect to the reference signal. In this state, the phase difference between the reference signal and the input signal from the

TB0_{IN} pin can be detected by measuring the pulse width by timer B0.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

The dead-time timer operates as a one-shot pulse timer. When a trigger arrives, the dead-time timer starts pulse output, and when the value of the timer reaches 00_{16} , it terminates pulse output, stops operation, and waits for the next trigger.

The output polarity of three-phase waveform depends on the output polarity setting toggle flip-flops. When the contents of the output polarity toggle flip-flops is "0", the positive phase waveform is output at "H" level, and when "1", it is output at "L" level (three-phase waveform is output using negative logic).

The output polarity setting toggle flip-flops each have output polarity setting buffers shown in Figure 39. When the contents of timer B2 counter reaches 0000_{16} , the contents of output polarity setting buffers is set in the output polarity setting toggle flip-flops. After this, the output polarity setting toggle flip-flops have polarity reversed for each termination of one-shot pulse of timer (timer A2, A1 or A0) corresponding to each phase.

An example of U phase waveform is shown in Figure 40 to explain waveform output operation. Writing "0" to the U phase waveform start level setting bit (bit 1 of 64_{16} address) and actuating timer B2 makes the three-phase waveform mode effective. When the contents of timer B2 counter reaches 0000_{16} , timer A2 starts one-shot pulse output. At this time, the contents ("0" in this case) of U phase output polarity setting buffer is set in the output polarity setting toggle flip-flop 2. At termination of one-shot pulse output of timer A2, the contents of the output polarity setting toggle flip-flop 2 changes from "0" to "1" and a one-shot pulse of the eight-bit dead-time timer is output to set a time so that the "L" level of U phase waveform and U phase waveform with the negative phase of U phase waveform does not overlap.

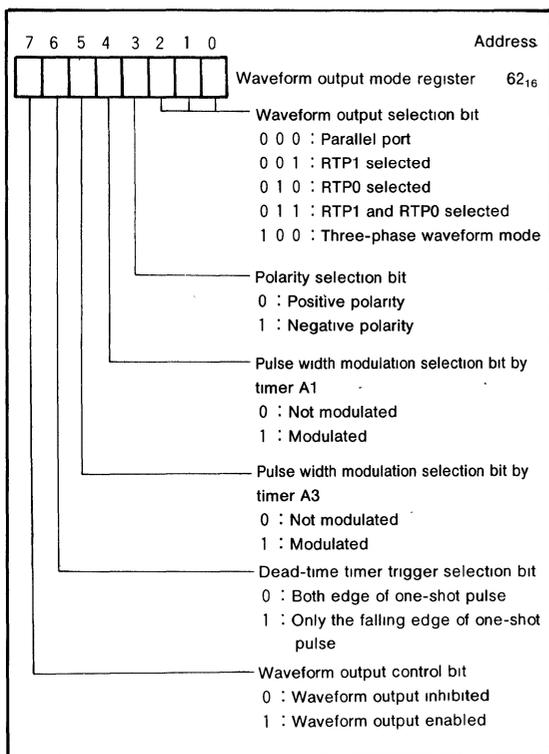

Fig. 36 Waveform output mode register bit configuration

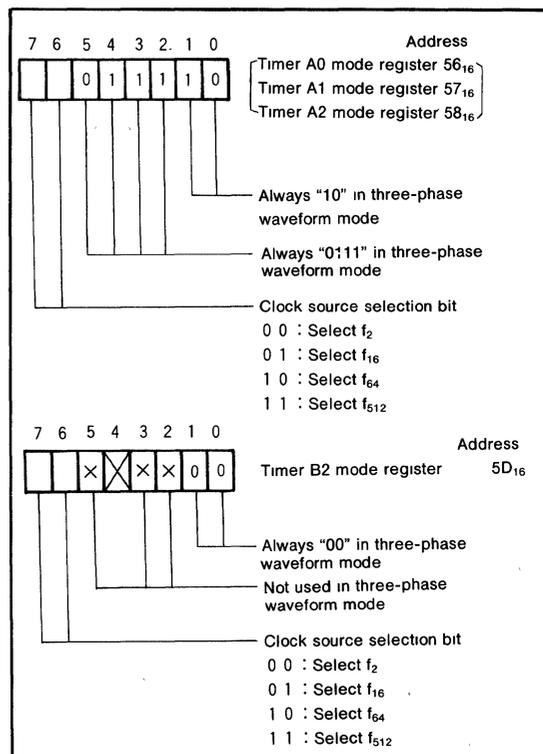

Fig. 37 Timer A0, A1, A2 mode register and timer B2 mode register bit configuration

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

The U-phase waveform output that began at "H" level remains at "H" level until termination of the one-shot pulse output of the dead-time timer, even when the contents of the output polarity setting toggle flip-flop 2 changes from "0" to "1" due to one-shot pulse output of timer A2. At termination of the one-shot pulse output of the dead-time timer, "1" of the output polarity setting toggle flip-flop 2 already reversed becomes effective and the U-phase waveform changes to "L" level. Next write "1" again to the U-phase output polarity setting buffer (bit 1 of 64₁₆ address) before the counter of timer B2 reaches 0000₁₆. When the counter of timer B2 reaches 0000₁₆, the one-shot pulse output of timer B2 begins to operate. At the same time, "1" written to the U-phase output polarity setting buffer is set in the output polarity setting toggle flip-flop 2 and the U-phase waveform output remains at "L" level. At termination of the one-shot pulse output of timer A2, the contents of the output polarity setting toggle flip-flop 2 changes from "1" to "0" and the one-shot pulse output of the dead-time timer begins to operate. The U-phase waveform output, when the contents of the output polarity setting toggle flip-flop changes from "1" to "0", changes from "L" to "H" without waiting for termination of the one-shot pulse output of the dead-time timer.

U-phase waveform is generated by repeating the above operation. \bar{U} -phase waveform with the negative phase of U-phase waveform is generated in the same way as U-phase waveform, except that the signal contents of the output polarity setting toggle flip-flop 2 is the very reverse of that in U-phase waveform. In this way, U-phase waveform and \bar{U} -phase waveform with the negative phase are generated from the pins so that the "L" level does not overlap.

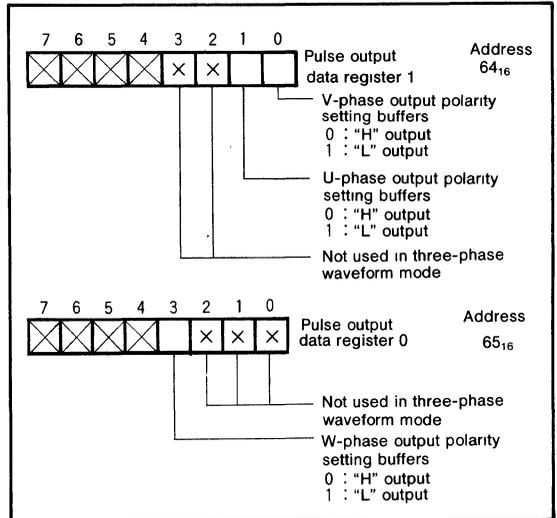

Fig. 39 Pulse output data register 0, 1 in three-phase waveform mode

The width of "L" level can be changed by changing the value of timer B2 and the value of timer A2. This technique for generating waveforms with "L" level not overlapping is also applicable to V phase, W phase, and their negative phases, \bar{V} phase and \bar{W} phase, by using corresponding timers.

The above explanation is for an example of generating three-phase waveform by the triangular wave modulation (called double edge modulation), but three-phase waveform by the saw-tooth-wave modulation (called signal edge modulation) can also be generated by fixing the start level of each phase.

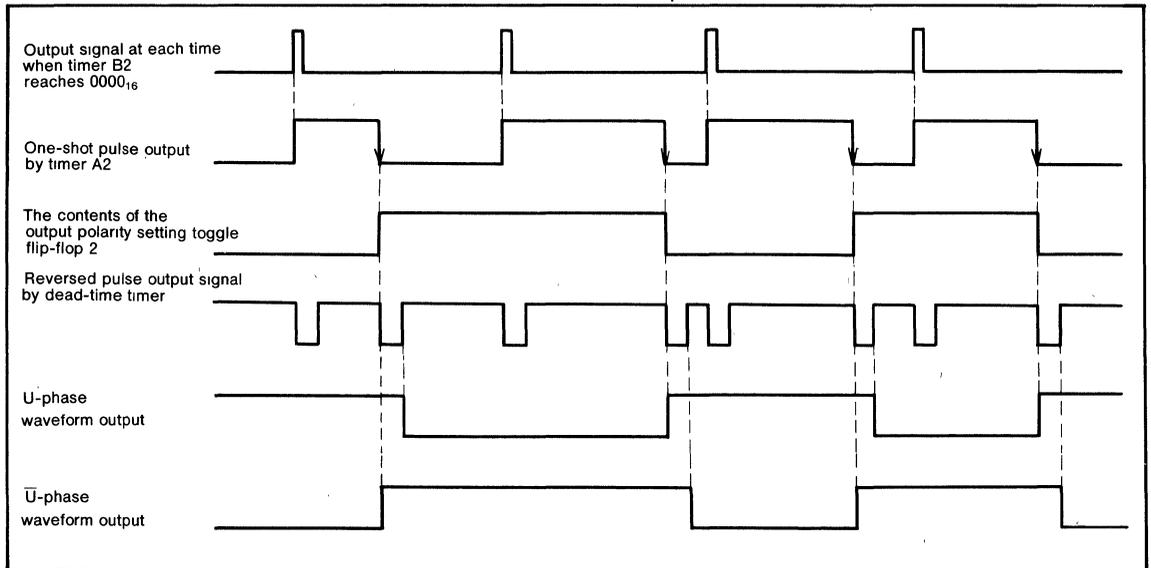

Fig. 40 Example of U-phase waveform output (three-phase waveform by triangular wave modulation)

MITSUBISHI MICROCOMPUTERS

M37704S1FP, M37704S1AFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

When "0" is written to a specified bit of the pulse output data register, "L" level is output to the corresponding pulse output port when the counter of corresponding timer becomes 0000_{16} , and when "1" is written, "H" level is output to the pulse output port.

Pulse width modulation can be applied to each pulse output port. Since pulse width modulation involves the use of timers A3 and A1, activate these timers in pulse width modulation mode. When a certain bit of the pulse output register is "1", pulse width modulation is output from the pulse output port when the counter of the corresponding timer becomes 0000_{16} .

Ports P6₀, P5₆, P5₅ and P5₄ are applied pulse width modulation by timer A3 by setting the pulse width modulation selection bit by timer A3 (bit 5) of the waveform output mode register to "1".

Ports P5₃, P5₂, P5₁ and P5₀ are applied pulse width modulation by timer A1 by setting the pulse width modulation selection bit by timer A1 (bit 4) of the waveform output mode register to "1".

The contents of the pulse output data register 0 can be reversed and output to pulse output ports P5₃, P5₂, P5₁ and P5₀ by the polarity selection bit (bit 3) of the waveform output mode register. When the polarity selection bit is "0", the contents of the pulse output data register 0 is output unchangeably, and when "1", the contents of the pulse output data register 0 is reversed and output. When pulse width modulation is applied, likewise the polarity reverse to pulse width modulation can be selected by the polarity selection bit.

Figure 44 shows example of waveforms in pulse output port mode.

Ports selecting the pulse output port mode can control output as in the three-phase waveform mode by the waveform output control bit (bit 7) of the waveform output mode register (62₁₆ address).

When the waveform output control bit is set to "1", a waveform is output from the port. When this bit is set to "0", waveform output from the port is stopped and the port is placed in floating state.

This bit can be set to "0" by instructions, by inputting a falling edge to the INT₀ pin, or reset.

SERIAL I/O PORTS

Two independent serial I/O ports are provided. Figure 45 shows a block diagram of the serial I/O ports.

Bits 0, 1, and 2 of the UART_i (i = 0, 1) Transmit/Receive mode register shown in Figure 46 are used to determine whether to use port P8 as parallel port, clock synchronous serial I/O port, or asynchronous (UART) serial I/O port us-

ing start and stop bits.

Figures 47 and 48 show the connections of receiver/transmitter according to the mode.

Figure 49 shows the bit configuration of the UART_i transmit/receive control register.

Each communication method is described below.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

CLOCK SYNCHRONOUS SERIAL COMMUNICATION

A case where communication is performed between two clock synchronous serial I/O ports as shown in Figure 50 will be described. (The transmission side will be denoted by subscript j and the receiving side will be denoted by subscript k.)

Bit 0 of the UARTj transmit/receive mode register and UARTk transmit/receive mode register must be set to "1" and bits 1 and 2 must be "0". The length of the transmission data is fixed at 8 bits.

Bit 3 of the UARTj transmit/receive mode register of the clock sending side is cleared to "0" to select the internal clock. Bit 3 of the UARTk transmit/receive mode register of the clock receiving side is set to "1" to select the external clock. Bits 4, 5 and 6 are ignored in clock synchronous mode. Bit 7 must always be "0".

The clock source is selected by bit 0 (CS_0) and bit 1 (CS_1) of the clock sending side UARTj transmit/receive control register 0. As shown in Figure 45, the selected clock is divided by $(n + 1)$, then by 2, passed through a transmission control circuit, and output as transmission clock CLKj. Therefore, when the selected clock is fi,

$$\text{Bit Rate} = f_i / \{ (n + 1) \times 2 \}$$

On the clock receiving side, the CS_0 and CS_1 bits of the UARTk transmit/receive control register are ignored because an external clock is selected.

The bit 2 of the clock sending side UARTj transmit/receive control register is clear to "0" to select $\overline{CTS_j}$ input. The bit 2 of the clock receiving side is set to "1" to select $\overline{RTS_k}$ output. CTS, and RTS signals are described later.

Transmission

Transmission is started when the bit 0 (TEj flag) of UARTj transmit/receive control register 1 is "1", bit 1 is (Tlj flag) of one is "0", and $\overline{CTS_j}$ input is "L". As shown in Figure 51, data is output from TxDj pin when transmission clock CLKj changes from "H" to "L". The data is output from the least significant bit.

The Tlj flag indicates whether the transmission buffer register is empty or not. It is cleared to "0" when data is written in the transmission buffer register and set to "1" when the contents of the transmission buffer register is transferred to the transmission register.

When the transmission register becomes empty after the contents has been transmitted, data is transferred automatically from the transmission buffer register to the transmission register if the next transmission start condition is satisfied. If the bit 2 of UARTj transmit/receive control register 0 is "1", $\overline{CTS_j}$ input is ignored and transmission start is controlled only by the TEj flag and Tlj flag. Once transmission has started, the TEj flag, Tlj flag, and $\overline{CTS_j}$ signals are ignored until data transmission completes. Therefore, trans-

mission is not interrupt when $\overline{CTS_j}$ input is changed to "H" during transmission.

The transmission start condition indicated by TEj flag, Tlj flag, and $\overline{CTS_j}$ is checked while the T_{END_j} signal shown in Figure 51 is "H". Therefore, data can be transmitted continuously if the next transmission data is written in the transmission buffer register and Tlj flag is cleared to "0" before the T_{END_j} signal goes "H".

The bit 3 (TxEPTYj flag) of UARTj transmit/receive control register 0 changes to "1" at the next cycle after the T_{END_j} signal goes "H" and changes to "0" when transmission starts. Therefore, this flag can be used to determine whether data transmission has completed.

When the Tlj flag changes from "0" to "1", the interrupt request bit in the UARTj transmission interrupt control register is set to "1".

Receive

Receive starts when the bit 2 (RE_k flag) of UARTk transmit/receive control register 1 is set to "1".

The $\overline{RTS_k}$ output is "H" when the RE_k flag is "0" and goes "L" when the RE_k flag changed to "1". It goes back to "H" when receive starts. Therefore, the $\overline{RTS_k}$ output can be used to determine whether the receive register is ready to receive. It is ready when $\overline{RTS_k}$ output is "L".

The data from the RxDk pin is retrieved and the contents of the receive register is shifted by 1 bit each time the transmission clock CLKj changes from "L" to "H". When an 8-bit data is received, the contents of the receive register is transferred to the receive buffer register and the bit 3 (RI_k flag) of UARTk transmit/receive control register 1 is set to "1". In other words, the setting of the RI_k flag indicates that the receive buffer register contains the received data. At this point, $\overline{RTS_j}$ output goes "L" to indicate that the next data can be received. When the RI_k flag changes from "0" to "1", the interrupt request bit in the UARTk receive interrupt control register is set to "1". Bit 4 (OER_k flag) of UARTk transmit/receive control register is set to "1" when the next data is transferred from the receive register to the receive buffer register while RI_k flag is "1", and indicates that the next data was transferred to the receive register before the contents of the receive buffer register was read. RI_k and OER_k flags are cleared automatically to "0" when the low-order byte of the receive buffer register is read. The OER_k flag is also cleared when the RE_k flag is cleared. Bit 5 (FER_k flag), bit 6 (PER_k flag), and bit 7 (SUM_k flag) are ignored in clock synchronous mode.

As shown in Figure 50, with clock synchronous serial communication, data cannot be received unless the transmitter is operating because the receive clock is created from the transmission clock. Therefore, the transmitter must be operating even when there is no data to be sent from UARTk to UARTj.

M37704S1FP, M37704S1AFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

ASYNCHRONOUS SERIAL COMMUNICATION

Asynchronous serial communication can be performed using 7-, 8-, or 9-bit length data. The operation is the same for all data lengths. The following is the description for 8-bit asynchronous communication.

With 8-bit asynchronous communication, the bit 0 of UARTi transmit/receive mode register is "1", the bit 1 is "0", and the bit 2 is "1".

Bit 3 is used to select an internal clock or an external clock. If bit 3 is "0", an internal clock is selected and if bit 3 is "1", then external clock is selected. If an internal clock is selected, the bit 0 (CS₀) and bit 1 (CS₁) of UARTi transmit/receive control register 0 are used to select the clock source. When an internal clock is selected for asynchronous serial communication, the CLK pin can be used as a normal I/O pin.

The selected internal or external clock is divided by (n+1), then by 16, and passed through a control circuit to create the UART transmission clock or UART receive clock.

Therefore, the transmission speed can be changed by changing the contents n of the bit rate generator. If the selected clock is an internal clock f_i or an external clock f_{EXT},

$$\text{Bit Rate} = (f_i \text{ or } f_{\text{EXT}}) / \{ (n+1) \times 16 \}$$

Bit 4 is the stop bit length selection bit to select 1 stop bit or 2 stop bits.

The bit 5 is a selection bit of odd parity or even parity.

In the odd parity mode, the parity bit is adjusted so that the sum of the 1's in the data and parity bit is always odd.

In the even parity mode, the parity bit is adjusted so that the sum of the 1's in the data and parity bit is always even.

M37704S1FP, M37704S1AFP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

If $\overline{\text{RTS}}_i$ output is selected by setting the bit 2 of UART_i transmit/receive control register 0 to "1", the $\overline{\text{RTS}}_i$ output is "H" when the RE_i flag is "0". When the RE_i flag changes to "1", the $\overline{\text{RTS}}_i$ output goes "L" to indicate receive ready and returns to "H" once receive has started. In other words, $\overline{\text{RTS}}_i$ output can be used to determine externally whether the receive register is ready to receive.

The entire transmission data bits are received when the start bit passes the final bit of the receive block shown in Figure 33. At this point, the contents of the receive register is transferred to the receive buffer register and the bit 3 of UART_i transmit/receive control register 1 is set. In other words, the RI_i flag indicates that the receive buffer register contains data when it is set. If $\overline{\text{RTS}}_i$ output is selected, $\overline{\text{RTS}}_i$ output goes "L" to indicate that the register is ready to receive the next data.

The interrupt request bit in the UART_i receive interrupt control register is set when the RI_i flag changes from "0" to "1".

The bit 4 (OER_i flag) of UART_i transmission control register 1 is set when the next data is transferred from the receive register to the receive buffer register while the RI_i flag is "1". In other words when an overrun error occurs. If the OER_i flag is "1", it indicates that the next data has been transferred to the receive buffer register before the contents of the receive buffer register has been read.

Bit 5 (FER_i flag) is set when the number of stop bits is less than required (framing error).

Bit 6 (PER_i flag) is set when a parity error occurs.

Bit 7 (SUM_i flag) is set when either the OER_i flag, FER_i flag, or the PER_i flag is set. Therefore, the SUM_i flag can be used to determine whether there is an error.

The setting of the RI_i flag, OER_i flag, FER_i flag, and the PER_i flag is performed while transferring the contents of the receive register to the receive buffer register. The RI_i , OER_i , FER_i , PER_i , and SUM_i flags are cleared when the low order byte of the receive buffer register is read or when the RE_i flag is cleared.

Sleep mode

The sleep mode is used to communicate only between certain microcomputers when multiple microcomputers are connected through serial I/O.

The sleep mode is entered when the bit 7 of UART_i transmit/receive mode register is set.

The operation of the sleep mode for an 8-bit asynchronous communication is described below.

When sleep mode is selected, the contents of the receive register is not transferred to the receive buffer register if bit 7 (bit 6 if 7-bit asynchronous communication and bit 8 if 9-bit asynchronous communication) of the received data is "0". Also the RI_i , OER_i , FER_i , PER_i , and the SUM_i flag are unchanged. Therefore, the interrupt request bit of the UART_i receive interrupt control register is also unchanged.

Normal receive operation takes place when bit 7 of the received data is "1".

The following is an example of how the sleep mode can be used.

The main microcomputer first sends data with bit 7 set to "1" and bits 0 to 6 set to the address of the subordinate microcomputer which wants to communicate with. Then all subordinate microcomputers receive the same data. Each subordinate microcomputer checks the received data, clears the sleep bit if bits 0 to 6 are its own address and sets the sleep bit if not. Next the main microcomputer sends data with bit 7 cleared. Then the microcomputer with the sleep bit cleared will receive the data, but the microcomputer with the sleep bit set will not. In this way, the main microcomputer is able to communicate with only the designated microcomputer.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

(1) One-shot mode [00]

The A-D conversion pins are selected with the bit 0 to 2 of A-D control register. A-D conversion can be started by a software trigger or by an external trigger.

A software trigger is selected when the bit 5 of A-D control register is "0" and an external trigger is selected when it is "1".

When a software trigger is selected, A-D conversion is started when bit 6 (A-D conversion start flag) is set. A-D conversion ends after 57 ϕ_{AD} cycles and an interrupt request bit is set in the A-D conversion interrupt control register. At the same time, A-D control register bit 6 (A-D conversion start flag) is cleared and A-D conversion stops. The result of A-D conversion is stored in the A-D register corresponding to the selected pin.

If an external trigger is selected, A-D conversion starts when the A-D conversion start flag is "1" and the $\overline{AD_{TRG}}$ input changes from "H" to "L". In this case, the pins that can be used for A-D conversion are AN_0 to AN_6 because the $\overline{AD_{TRG}}$ pin is shared with the analog voltage input pin AN_7 . The operation is the same as with software trigger except that the A-D conversion start flag is not cleared after A-D conversion and a retrigger can be available during A-D conversion.

(2) Repeat mode [01]

The operation of this mode is the same as the operation of one-shot mode except that when A-D conversion of the selected pin is complete and the result is stored in the A-D register, conversion does not stop, but is repeated. Also, no interrupt request is issued in this mode. Furthermore, if software trigger is selected, the A-D conversion start flag is not cleared. The contents of the A-D register can be read at any time.

(3) Single sweep mode [10]

In the sweep mode, the number of analog input pins to be swept can be selected. Analog input pins are selected by bits 1 and 0 of the A-D sweep pin selection register (1F₁₆ address) shown in Figure 57. Two pins, four pins, six pins, or eight pins can be selected as analog input pins, depending on the contents of these bits.

A-D conversion is performed only for selected input pins. After A-D conversion is performed for input of AN_0 pin, the conversion result is stored in A-D register 0, and in the same way, A-D conversion is performed for selected pins one after another. After A-D conversion is performed for all selected pins, the sweep is stopped.

A-D conversion can be started with a software trigger or with an external trigger input. A software trigger is selected when bit 5 is "0" and an external trigger is selected when it is "1".

When a software trigger is selected, A-D conversion is started when A-D control register bit 6 (A-D conversion start flag) is set. When A-D conversion of all selected pins end, an interrupt request bit is set in the A-D conversion in-

terrupt control register. At the same time, A-D control register bit 6 (A-D conversion start flag) is cleared and A-D conversion stops.

When an external trigger is selected, A-D conversion starts when the A-D conversion start flag is "1" and the $\overline{AD_{TRG}}$ input changes from "H" to "L". In this case, the A-D conversion result of the trigger input itself is stored in the A-D register 7 because the $\overline{AD_{TRG}}$ pin is shared with AN_7 pin.

The operation is the same as done by software trigger except that the A-D conversion start flag is not cleared after A-D conversion and a retrigger can be available during A-D conversion.

(4) Repeat sweep mode [11]

The difference with the single sweep mode is that A-D conversion does not stop after converting from the AN_0 pin to the selected pins, but repeats again from the AN_0 pin. The repeat is performed among the selected pins. Also, no interrupt request is generated. Furthermore, if software trigger is selected, the A-D conversion start flag is not cleared. The A-D register can be read at any time.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

RESET CIRCUIT

Reset occurs when the $\overline{\text{RESET}}$ pin is returned to "H" level after holding it at "L" level when the power voltage is at $5V \pm 10\%$. Program execution starts at the address formed by setting the address pins $A_{23} \sim A_{16}$ to 00_{16} , $A_{15} \sim A_8$ to the contents of address FFF_{16} , and $A_7 \sim A_0$ to the contents of address FFE_{16} .

Figure 60 shows the status of the internal registers when a reset occurs.

Figure 61 shows an example of a reset circuit. The reset input voltage must be held 0.9V or lower when the power voltage reaches 4.5V.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

ALE is an address latch enable signal used to latch the address signal from a multiplexed signal of address and data. The latch is transparent while ALE is "H" to let the address signal pass through and held while ALE is "L".

HLDA is a hold acknowledge signal and is used to notify externally when the microcomputer receives $\overline{\text{HOLD}}$ input and enters into hold state.

Ports P4₀ and P4₁ become $\overline{\text{HOLD}}$ and $\overline{\text{RDY}}$ input pin respectively and lose their output pin function, but the input pin function remains.

HOLD is a hold request signal. It is an input signal used to put the microcomputer in hold state. Ports P0, P1, P2, P3₀, and P3₁ are floating while the microcomputer stays in hold state.

RDY is a ready signal. If this signal goes "L", the internal clock ϕ stops at "L". When ϕ_1 output from port P4₂ is selected by setting bit 7 of processor mode register to "1", ϕ_1 output keeps on. RDY is used when slow external memory is attached.

(3) Microprocessor mode [10]

Microprocessor mode is entered by connecting the CNV_{SS} pin to V_{CC} and starting from reset. It can also be entered by programming the processor mode bits to "10" after connecting the CNV_{SS} pin to V_{SS} and starting from reset. This mode is similar to memory expansion mode except that internal ROM is disabled and an external memory is required, and ϕ_1 from port P4₂ is always output in spite of bit 7 of processor mode register.

(4) Evaluation chip mode [11]

Evaluation chip mode is entered by applying voltage twice the V_{CC} voltage to the CNV_{SS} pin. This mode is normally used for evaluation tools.

The functions of ports P0 and P3 are the same as in memory expansion mode.

Port P1 functions as an address output pin while $\overline{\text{E}}$ is "H" and as data I/O pin of odd addresses while $\overline{\text{E}}$ is "L" regardless of the BYTE pin level. However, if an internal memory is read, external data is ignored while $\overline{\text{E}}$ is "L".

Port P2 function as an address output pin while $\overline{\text{E}}$ is "H" and as data I/O pin of even addresses while $\overline{\text{E}}$ is "L" when the BYTE pin level is "L". However, if an internal memory is read, external data is ignored while $\overline{\text{E}}$ is "L".

When the BYTE pin level is "H" or 2·V_{CC}, port P2 functions as an address output pin while $\overline{\text{E}}$ is "H" and as data I/O pin of even and odd addresses while $\overline{\text{E}}$ is "L". However, if an internal memory is read, external data is ignored while $\overline{\text{E}}$ is "L".

Port P4 and its data direction register which are located at address 0A₁₆ and 0C₁₆ are treated differently in evaluation chip mode. When these addresses are accessed, the data bus width is treated as 16 bits regardless of the BYTE pin level, and the access cycle is treated as internal memory regardless of the wait bit.

When a voltage twice the V_{CC} voltage is applied to the

BYTE pin, the addresses corresponding to the internal ROM area are also treated as 16-bit data bus.

The functions of ports P4₀ and P4₁ are the same as in memory expansion mode.

Ports P4₂ to P4₆ become ϕ_1 , MX, QCL, VDA, and VPA output pins respectively. Port P4₇ becomes the $\overline{\text{DBC}}$ input pin. ϕ_1 from port P4₂ divided the clock to X_{IN} pin by 2 is always output in spite of bit 7 of processor mode register.

The MX signal normally contains the contents of flag m, but the contents of flag x is output if the CPU is using flag x.

QCL is the queue buffer clear signal. It becomes "H" when the instruction queue buffer is cleared, for example, when a jump instruction is executed.

VDA is the valid data address signal. It becomes "H" while the CPU is reading data from data buffer or writing data to data buffer. It also becomes "H" when the first byte of the instruction (operation code) is read from the instruction queue buffer.

VPA is the valid program address signal. It becomes "H" while the CPU is reading an instruction code from the instruction queue buffer.

$\overline{\text{DBC}}$ is the debug control signal and is used for debugging.

Table 5 shows the relationship between the CNV_{SS} pin input levels and processor modes.

Table 5. Relationship between the CNV_{SS} pin input levels and processor modes

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

DESCRIPTION

The M37705M2-XXXSP, M37705M2AXXXSP, M37705S1SP, and M37705S1ASP are single-chip microcomputers designed with high-performance CMOS silicon gate technology. These are housed in a 64-pin shrink plastic molded DIP. These single-chip microcomputers have a large 16M bytes address space, three instruction queue buffers, and two data buffers for high-speed instruction execution. The CPU is a 16-bit parallel processor that can also be switched to perform 8-bit parallel processing. These microcomputers are suitable for office, business and industrial equipment controller that require high-speed processing of large data.

Also, the incorporated motor control circuit makes these microcomputers suitable for control of equipment that requires motor control.

The differences between M37705M2-XXXSP, M37705M2AXXXSP, M37705S1SP and M37705S1ASP are the ROM size and the external clock input frequency as shown below. Therefore, the following descriptions will be for the M37705M2-XXXFP unless otherwise noted.

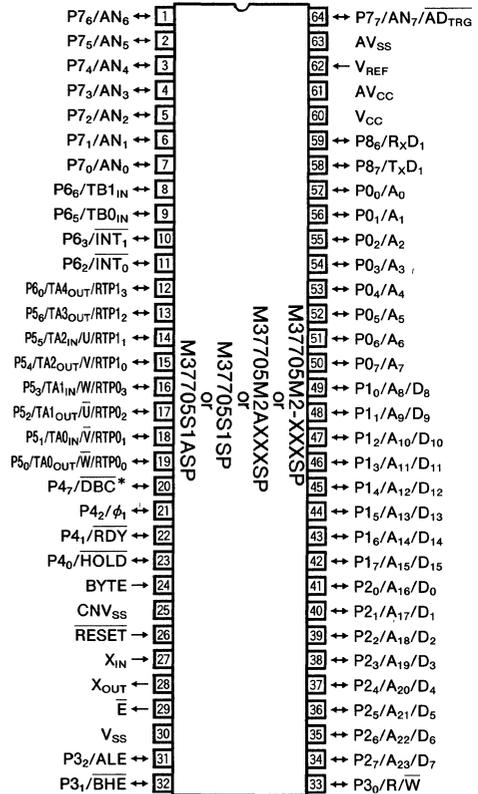

Type name	ROM size	External clock input frequency
M37705M2-XXXSP	16K bytes	8 MHz
M37705M2AXXXSP	16K bytes	16MHz
M37705S1SP	External	8 MHz
M37705S1ASP	External	16MHz

The M37705M2-XXXSP cuts down the pins of M37704M2-XXXFP. Refer to the section on M37704M2-XXXFP for the functional differences.

DISTINCTIVE FEATURES

- Number of basic instructions.....103
- Memory size ROM16K bytes
RAM.....512 bytes
- Instruction execution time
M37705M2-XXXSP, M37705S1SP
(The fastest instruction at 8 MHz frequency) 500ns
M37705M2AXXXSP, M37705S1ASP
(The fastest instruction at 16 MHz frequency)..... 250ns
- Single power supply.....5V±10%
- Low power dissipation (at 8 MHz frequency)
.....30mW (Typ.)
- Interrupts 16 types 7 levels
- Multiple function 16-bit timer5+3
(Three-phase motor drive waveform or pulse motor drive waveform can be output.)
- UART 1
- 8-bit A-D converter 8-channel inputs
- 12-bit watchdog timer
- Programmable input/output
(ports P0, P1, P2, P3, P4, P5, P6, P7, P8) 53

PIN CONFIGURATION (TOP VIEW)

Outline 64P4B

*: Used in the evaluation chip mode only

APPLICATION

Control devices for office equipment such as copiers, printers, typewriters, facsimiles, word processors, and personal computers

Control devices for industrial equipment such as ME, NC, general purpose inverter, and measuring instruments

FUNCTIONS OF M37705M2-XXXSP

Parameter		Functions
Number of basic instructions		103
Instruction execution time	M37705M2-XXXSP, M37705S1SP	500ns (the fastest instructions, at 8MHz frequency)
	M37705M2AXXXSP, M37705S1ASP	250ns (the fastest instructions, at 16MHz frequency)
Memory size	ROM	16K bytes
	RAM	512 bytes
Input/Output ports	P0, P1, P2, P7	8-bitX 4
	P5	7-bitX 1
	P6	5-bitX 1
	P4	4-bitX 1
	P3	3-bitX 1
	P8	2-bitX 1
Multi-function timers	TA0, TA1, TA2, TA3, TA4	16-bitX 5 (3 input/output and 2 output functions)
	TB0, TB1, TB2	16-bitX 3 (2 input functions)
Serial I/O		UART X1
A-D converter		8-bitX 1 (8 channels)
Watchdog timer		12-bitX 1
Dead-time timer		8-bitX 3
Interrupts		2 external types, 14 internal types (Each interrupt can be set the priority levels to 0 ~ 7)
Clock generating circuit		Built-in(externally connected to a ceramic resonator or quartz crystal resonator)
Supply voltage		5 V±10%
Power dissipation		30mW(at external 8 MHz frequency)
Input/Output characteristic	Input/Output voltage	5 V
	Output current	5 mA
Memory expansion		Maximum 16M bytes
Operating temperature range		-10~70°C
Device structure		CMOS high-performance silicon gate process
Package		64-pin shrink plastic molded DIP

16-BIT CMOS MICROCOMPUTER

DESCRIPTION

The M37795SJ, and the M37795STJ are 16-bit microcomputers designed with high-performance CMOS silicon gate technology. These are housed in a 84-pin PLCC. These microcomputers have a large 16M bytes address space, the instruction queue buffers, and the data buffers for high-speed instruction execution. The CPU is a 16-bit parallel processor that can also be switched to perform 8-bit parallel processing. Utilizing its built-in peripheral functions such as timer system, 10-bit A-D converter and pulse width modulator (PWM), the M37795SJ and the M37795STJ are especially suited for industrial machinery applications that require real time control capability.

The M37795STJ is a version of the M37795SJ that has been upgraded for use in automobile vehicles. Its function and performance are same as for the M37795SJ, but it has a different operating temperature range which is shown below.

Therefore, the following descriptions will be for the M37795SJ unless other wise noted.

DISTINCTIVE FEATURES

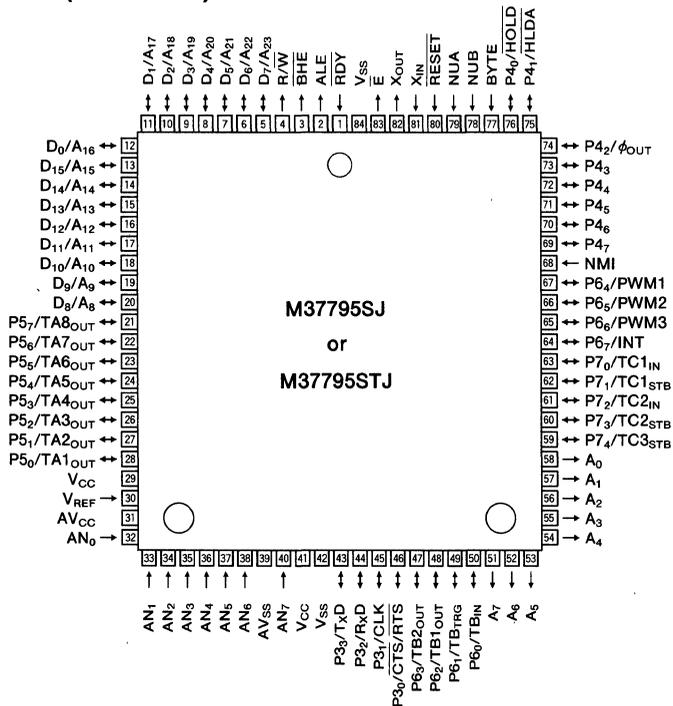

- Number of basic instructions.....103
- Instruction execution time
(The fastest instruction at 8 MHz frequency)500 ns
- Single power supply5V±10%
- Low power dissipation (at 8 MHz frequency)50mW (Typ.)
- MemoryROM/RAM external
- Interrupt20 types, 7 level
- 16-bit timer16
- PWM3
- UART (may also be synchronous)1
- 10-bit A-D converter8 channel input
- Watchdog timer1
- Programmable input/output
(ports P3, P4, P5, P6, P7,)33

APPLICATION

For factory automation system, automobiles and other industrial machinery control.

Type name	Operating temperature range
M37795SJ	-20~75°C
M37795STJ	-40~85°C

PIN CONFIGURATION (TOP VIEW)

FUNCTIONS OF M37795SJ

Parameter		Functions
Number of basic instructions		103
Instruction execution time		500ns (the fastest instructions, at 8MHz frequency)
Memory		ROM/RAM external
Input/Output port	P4~P6	8-bitX3
	P3	4-bitX1
	P7	5-bitX1
Analog input port	AN ₀ ~AN ₇	8-bitX1
Multi-function 16-bit Timer	TA1~TA8	16-bitX8
	TB1~TB4	16-bitX4
	TC1~TC3	16-bitX3
	TD	16-bitX1
PWM		8-bitX3
A-D converter		10-bitX1 (8 channels)
Serial I/O		(UART or Clock Synchronous)X1
Watchdog timer		12-bitX1
Interrupts		4 external types, 16 internal types Maskable interrupt factor is capable of setting the Interrupt Priority Level (IPL) of 0 to 7 for each factor.
Clock generating circuit		Built-in (externally connected ceramic or quartz crystal oscillator)
Supply voltage		5V±10%
Power dissipation		50mW (at external 8MHz frequency)
Operating temperature range	M37795SJ	-20~75°C
	M37795STJ	-40~85°C
Device structure		CMOS high-performance silicon gate process
Package		84-pin PLCC

MITSUBISHI MICROCOMPUTERS
M37795SJ, M37795STJ

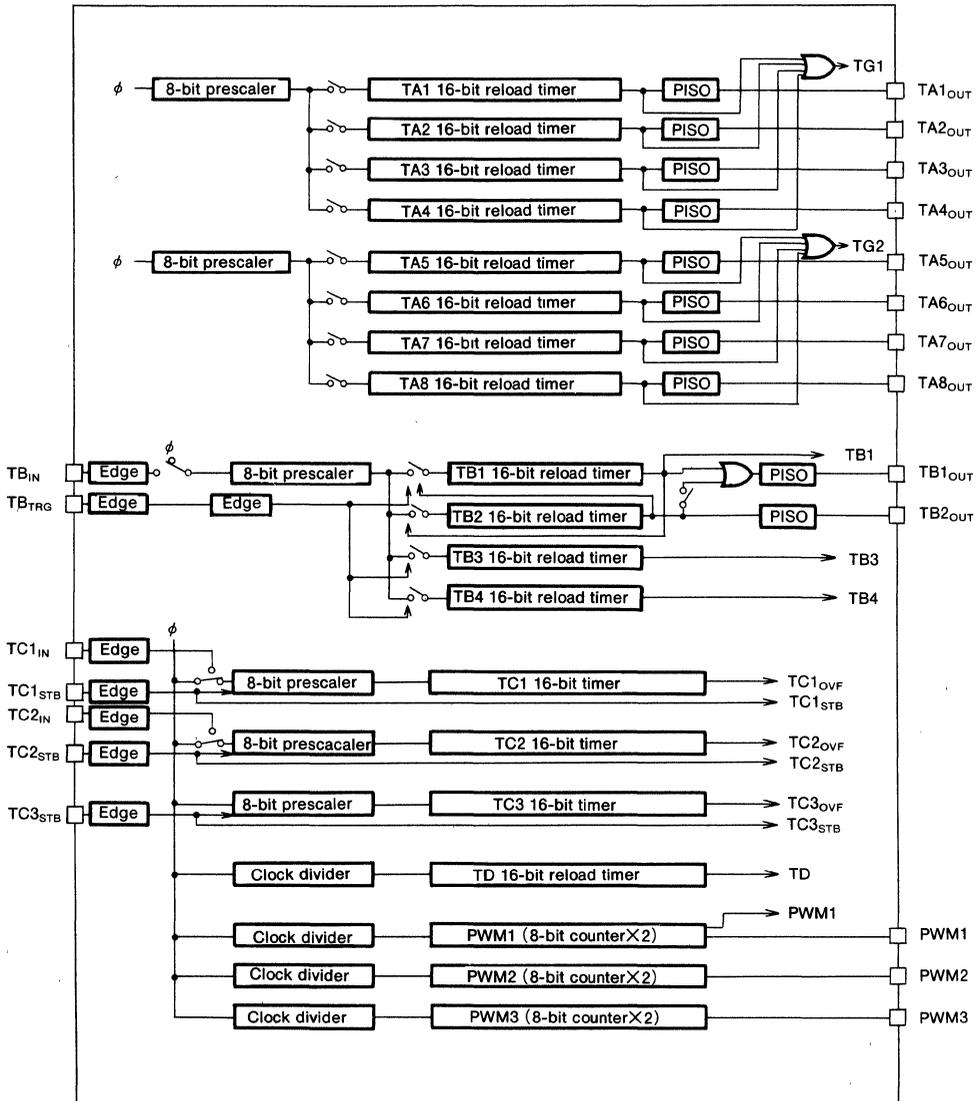

16-BIT CMOS MICROCOMPUTER

Pin	Name	Input/ Output	Functions
P4 ₀ ~P4 ₇	I/O port P4	I/O	This is a CMOS input/output port P4 ₀ , P4 ₁ and P4 ₂ have double functions, which can be selected by software
$\overline{\text{HOLD}}$ (P4 ₀)	Hold request signal	Input	This is the hold request input to the CPU. Input of "L" level sets the CPU in the hold status when the currently executing bus cycle is finished. Input of "H" level releases the hold and the CPU resumes execution
$\overline{\text{HLDA}}$ (P4 ₁)	Hold acknowledge signal	Output	When CPU is in the hold status, "L" level signal is output
ϕ_{OUT} (P4 ₂)	System clock output	Output	This is the external output of CPU system clock (ϕ)
P5 ₀ ~P5 ₇	I/O port P5	I/O	This is a CMOS input/output port. All 8 bits have double functions, which can be selected by software
TA1 _{OUT} ~TA8 _{OUT} (P5 ₀ ~P5 ₇)	PISO data output	Output	PISO data update by synchronizing with the timer underflow, etc. of the timers, TA1~TA8
P6 ₀ ~P6 ₇	I/O port P6	I/O	This is a CMOS input/output port. All 8 bits have double functions, which can be selected by software.
TB _{IN} (P6 ₀)	Timer B clock	Input	This signal is used as the clock input for the timers, TB1~TB4
TB _{TRG} (P6 ₁)	Timer B trigger	Input	This is the trigger signal input for the timers, TB1, TB3 and TB4
TB1 _{OUT} (P6 ₂) TB2 _{OUT} (P6 ₃)	PISO data output	Output	PISO data update by synchronizing with the timer underflow, etc. of the timers, TB1 and TB2
PWM1 ~PWM3 (P6 ₄ ~P6 ₆)	PWM output	Output	Output pulse of this pin is generated by PWM
INT(P6 ₇)	External interrupt input	Input	This is the interrupt input pin. Edge sense or level sense can be specified
P7 ₀ ~P7 ₄	I/O port P7	I/O	This is a CMOS input/output port. All 5 bits have double functions, which can be selected by software.
TC1 _{IN} (P7 ₀)	Timer C1 clock	Input	This is the timer TC1's clock input
TC1 _{STB} (P7 ₁)	Timer C1 strobe	Input	This is the strobe signal input for timer TC1's measurement function
TC2 _{IN} (P7 ₂)	Timer C2 clock	Input	This is the timer TC2's clock input.
TC2 _{STB} (P7 ₃)	Timer C2 strobe	Input	This is the strobe signal input for timer TC2's measurement function.
TC3 _{STB} (P7 ₄)	Timer C3 strobe	Input	This is the strobe signal input for timer TC3's measurement function
AN ₀ ~AN ₇	Analog input port	Input	This is an 8-bit analog input pin to the A-D converter

16-BIT CMOS MICROCOMPUTER

M37795SJ

ELECTRICAL CHARACTERISTICS ($V_{CC}=5V\pm 10\%$, $T_a=-20\sim 75^\circ C$, $f(X_{IN})=8MHz$, unless otherwise noted)

Symbol	Parameter	Test conditions	Limits			Unit
			Min.	Typ.	Max.	
V_{OH}	High-level output voltage	$I_{OH}=-2mA$	$V_{CC}-1$			V
V_{OL}	Low-level output voltage	$I_{OL}=2mA$			0.45	V
I_{IH}	High-level input current	$V_i=V_{CC}$	-5		5	μA
I_{iL}	Low-level input current	$V_i=0V$	-5		5	μA
I_{CC}	Power supply current (Note 1)	$f(X_{IN})=8MHz$ square waveform		8(Note 2)	20	mA
		$T_a=25^\circ C$ when clock is stopped			1	μA
		$T_a=75^\circ C$ when clock is stopped			15	μA
$V_{T+}-V_{T-}$	Hysteresis TB_{IN} , TB_{TRG} , $TC1_{IN}$, $TC2_{IN}$, $TC1_{STB}$, $TC2_{STB}$, $TC3_{STB}$, $RESET$ (Note3)	$V_{CC}=5V$	0.8			V
$V_{T+}-V_{T-}$	Hysteresis $HOLD$, INT , CLK , CTS/RTS , NMI , RDY (Note 4)	$V_{CC}=5V$	0.2			V

- Note 1. When reset with output pins open and connecting input pins to V_{SS} .
 2. $V_{CC}=5V$, $T_a=25^\circ C$
 3. Double function except for $RESET$ pin
 4. Double function except for NMI and RDY pins.

A-D CONVERTER CHARACTERISTICS ($AV_{CC}=V_{REF}=5.12V$, $T_a=25^\circ C$, $f(X_{IN})=8MHz$)

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
—	Resolution			10	Bits
—	Absolute accuracy			± 3	LSB
t_{CONV}	Conversion time	40.5			μs
I_{IAN}	Analog input leak current (Note 1)	-200		200	nA

- Note 1. Input leak current of $AN_0\sim AN_7$ with A-D converter halted
 Input voltage is $0\leq V_i\leq AV_{CC}$.

TIMING REQUIREMENTS ($V_{CC}=5V\pm 10\%$, $T_a=-20\sim 75^\circ C$, $f(X_{IN})=8MHz$)

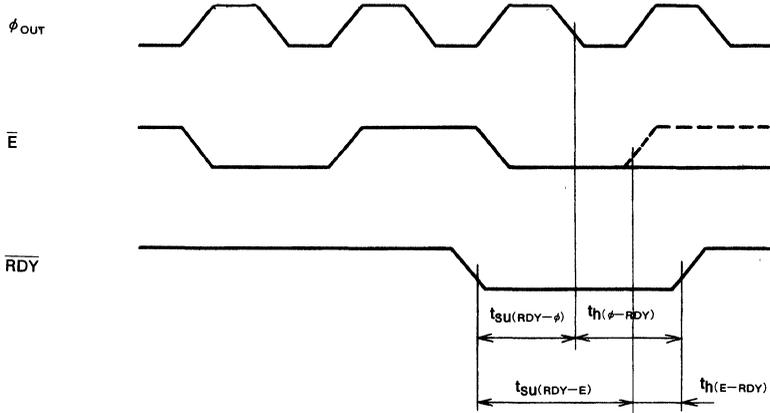

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
t_C	Cycle time	125			ns
$t_{SU(D-E)}$	Data input setup time	80			ns
$t_{H(E-D)}$	Data input hold time	0			ns

16-BIT CMOS MICROCOMPUTER

RDY characteristics ($V_{CC}=5V\pm 10\%$, $T_a=-20\sim 75^\circ C$, $f(X_{IN})=8MHz$)

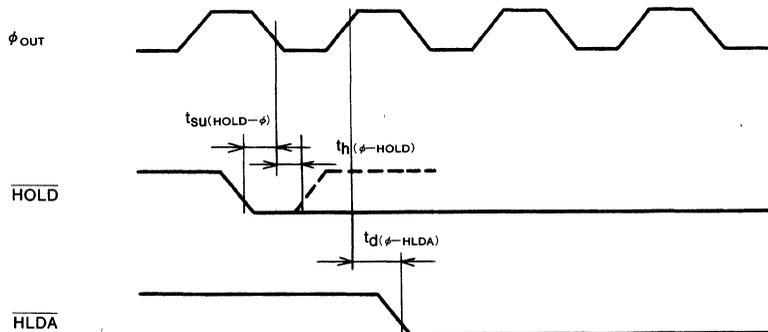

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
$t_{SU(RDY-\phi)}$	RDY input setup time	100		220	ns
$t_{H(\phi-RDY)}$	RDY input hold time	60			ns
$t_{SU(RDY-E)}$	RDY input setup time	220		300	ns
$t_{H(E-RDY)}$	RDY input hold time	-20			ns

Note. Follow the characteristics of ϕ or \bar{E} .

HOLD characteristics ($V_{CC}=5V\pm 10\%$, $T_a=-20\sim 75^\circ C$, $f(X_{IN})=8MHz$)

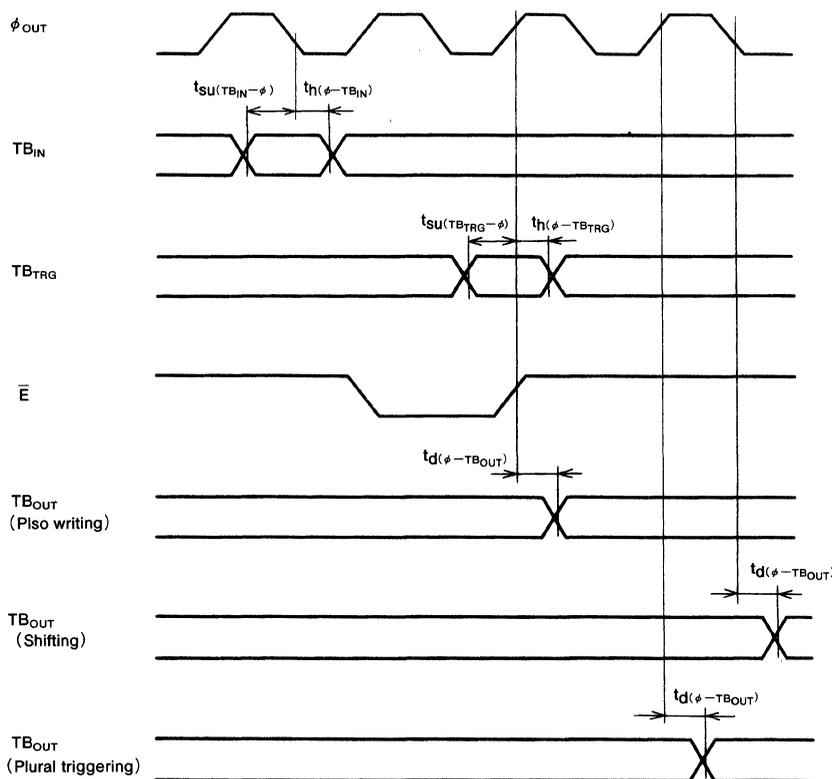

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
$t_{SU(HOLD-\phi)}$	HOLD input setup time	100			ns
$t_{H(\phi-HOLD)}$	HOLD input hold time	30			ns
$t_{d(\phi-HLDA)}$	HLDA output delay time			80	ns

Timer B characteristics ($V_{CC}=5V\pm 10\%$, $T_a=-20\sim 75^\circ C$, $f(X_{IN})=8MHz$)

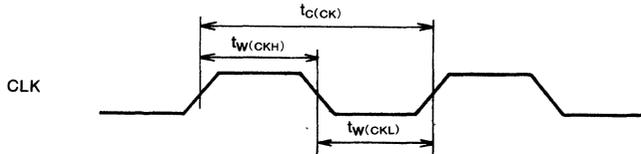

Symbol	Parameter	Limits			Unit
		Min	Typ.	Max.	
$t_{SU}(TB_{IN}-\phi)$	TB _{IN} input setup time	200			ns
$t_{H}(\phi-TB_{IN})$	TB _{IN} input hold time	0			ns
$t_{SU}(TB_{STB}-\phi)$	TB _{STB} input setup time	200			ns
$t_{H}(\phi-TB_{STB})$	TB _{STB} input hold time	0			ns
$t_{d}(\phi-TB_{OUT})$	TB _{OUT} output delay time	PISO writing		200	ns
		Shifting		200	
		Plural triggering (Note 1)		200	

Note 1. Shift by TB2 underflow with plural trigger.

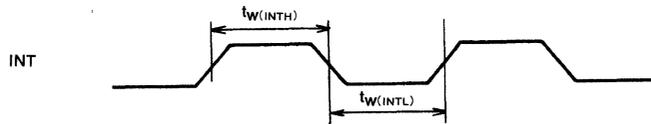

UART characteristics ($V_{CC}=5V\pm 10\%$, $T_a=-20\sim 75^\circ C$, $f(X_{IN})=8MHz$)

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
$t_{C(CK)}$	CLK input cycle time	500			ns
$t_{W(CKH)}$	CLK input high-level pulse width	250			ns
$t_{W(CKL)}$	CLK input low-level pulse width	250			ns

INT characteristics ($V_{CC}=5V\pm 10\%$, $T_a=-20\sim 75^\circ C$, $f(X_{IN})=8MHz$)

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
$t_{W(INTH)}$	INT input high-level pulse width	250			ns
$t_{W(INTL)}$	INT input low-level pulse width	250			ns

SWITCHING CHARACTERISTICS ($V_{CC}=5V\pm 10\%$, $T_a=-40\sim 85^\circ C$, $f(X_{IN})=8MHz$)

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
$t_{W(ALE)}$	ALE pulse width	80			ns
$t_{C(ALE-E)}$	\bar{E} end time after ALE	300			ns
$t_{d(ALE-E)}$	\bar{E} start time after ALE	0			ns
$t_{W(E)}$	\bar{E} pulse width	180			ns
$t_{pZV(E-DZ)}$	Floating release delay time	60			ns
$t_{d(A-E)}$	Address output delay time	100			ns
$t_{pVZ(E-DZ)}$	Floating start delay time			40	ns
$t_{d(E-D)}$	Data output delay time			100	ns
$t_{V(ALE-A)}$	Address delay time after ALE	10			ns
$t_{V(E-D)}$	Data valid time after \bar{E}	10			ns
$t_{V(E-A)}$	Address valid time after \bar{E}	10			ns
$t_{d(CONT-E)}$	Control signal delay time	100			ns
$t_{V(E-CONT)}$	Control signal valid time	10			ns

Note. Limits have guaranties under load capacity of the test pin=100pF including test tool's capacity. If capacities of pins are much different from each other, limits may not be followed. So pay attention to the design of the board.

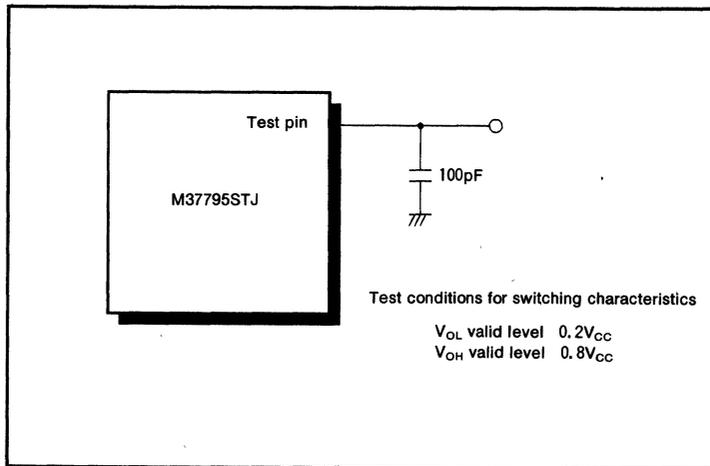

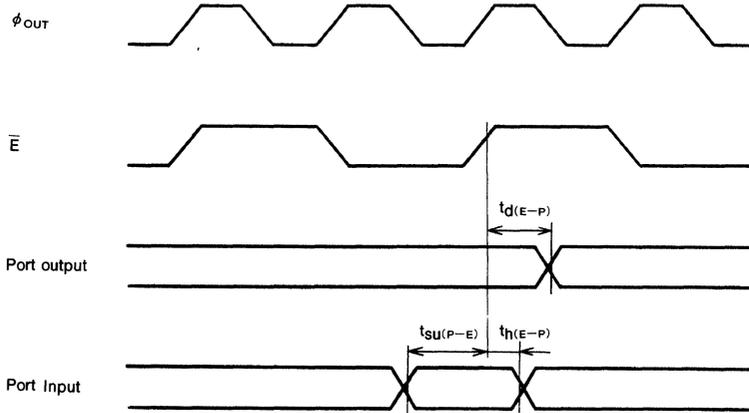

Fig. 5 Testing circuit

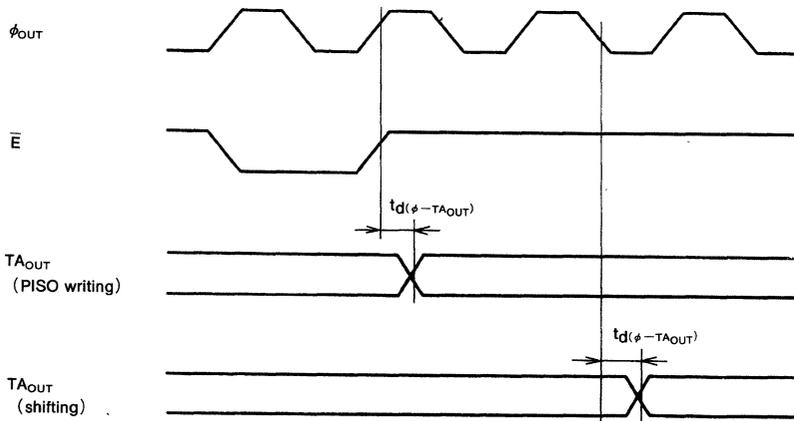

Port characteristics ($V_{CC}=5V\pm 10\%$, $T_a=-40\sim 85^\circ C$, $f(X_{IN})=8MHz$)

Symbol	Parameter	Limits			Unit
		Min	Typ.	Max.	
$t_{SU(P-E)}$	Port input setup time	200			ns
$t_{H(E-P)}$	Port input hold time	20			ns
$t_{d(E-P)}$	Port data output delay time			200	ns

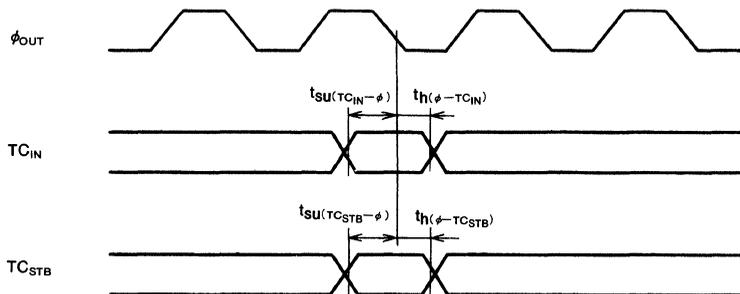

Timer A characteristics ($V_{CC}=5V\pm 10\%$, $T_a=-40\sim 85^\circ C$, $f(X_{IN})=8MHz$)

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
$t_{d(\phi-TA_{OUT})}$	TA_{OUT} output delay time	PISO writing		200	ns
		Shifting		200	ns

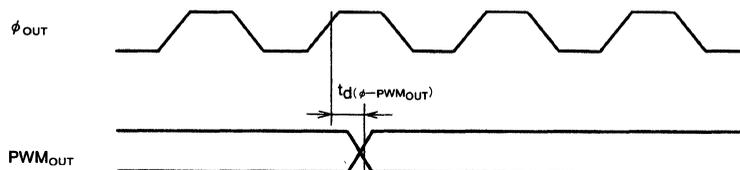

Timer C characteristics ($V_{CC}=5V\pm 10\%$, $T_a=-40\sim 85^\circ C$, $f(X_{IN})=8MHz$)

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
$t_{SU}(TC_{IN}-\phi)$	TC_{IN} input setup time	200			ns
$t_{H}(\phi-TC_{IN})$	TC_{IN} input hold time	0			ns
$t_{SU}(TC_{STB}-\phi)$	TC_{STB} input setup time	200			ns
$t_{H}(\phi-TC_{STB})$	TC_{STB} input hold time	0			ns

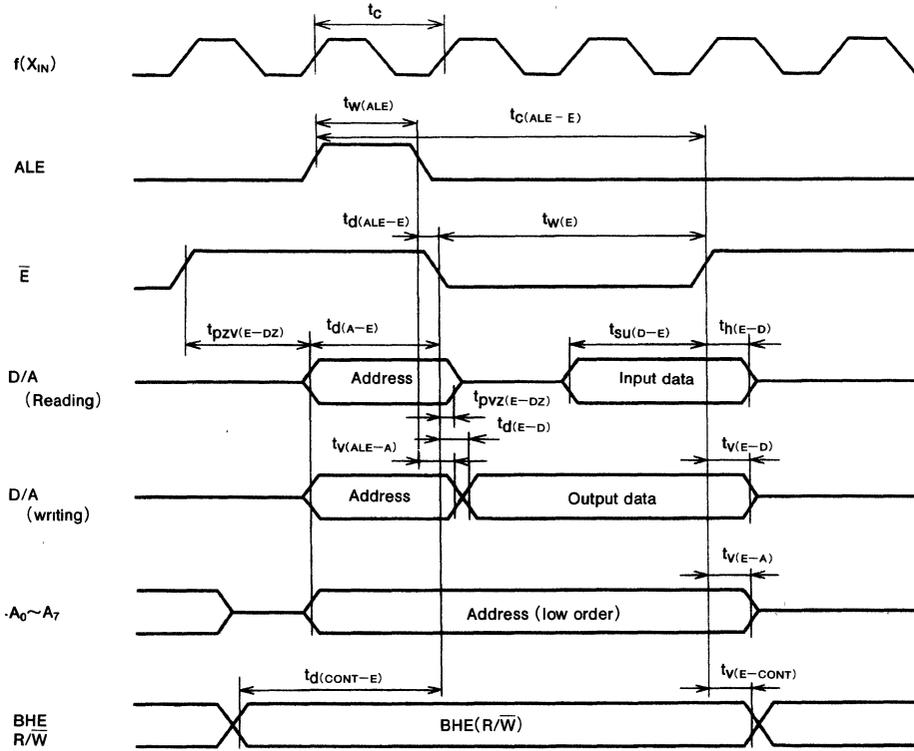

PWM characteristics ($V_{CC}=5V\pm 10\%$, $T_a=-40\sim 85^\circ C$, $f(X_{IN})=8MHz$)

Symbol	Parameter	Limits			Unit
		Min.	Typ.	Max.	
$t_{d}(\phi-PWM_{OUT})$	PWM_{OUT} output delay time			200	ns

TIMING DIAGRAM

MITSUBISHI MICROCOMPUTERS SERIES MELPS 7700 ADDRESSING MODES

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

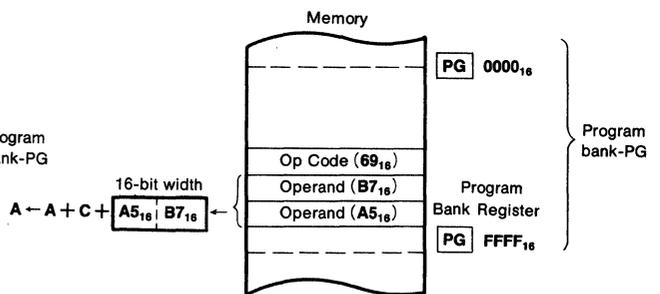

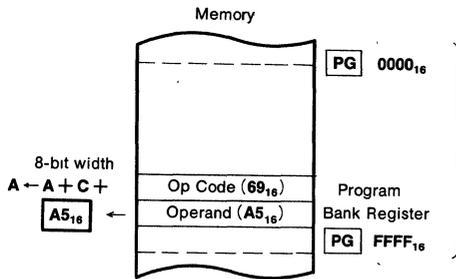

Mode : Immediate addressing mode

Function : A portion of the instruction is the actual data.
Such instruction code may cross over the bank boundary.

Instruction : **ADC, AND, CLP, CMP, CPX, CPY, DIV, EOR, LDA, LDT, LDY, MPY, ORA, RLA, SBC, SEP**

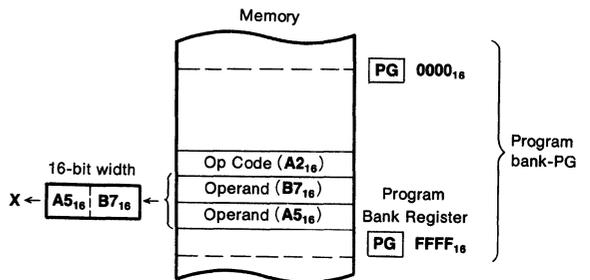

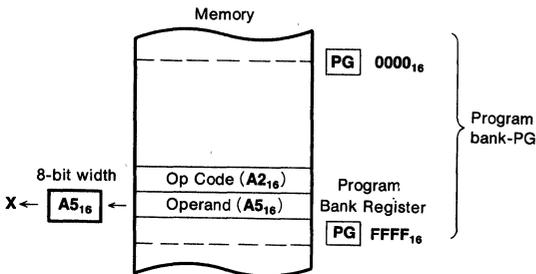

ex. : Mnemonic Machine code
ADC A, #0A5H **69₁₆ A5₁₆**

MITSUBISHI MICROCOMPUTERS SERIES MELPS 7700 ADDRESSING MODES

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

Mode : Relative addressing mode

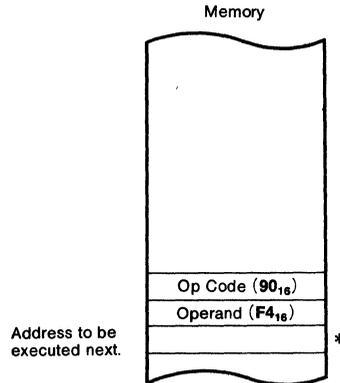

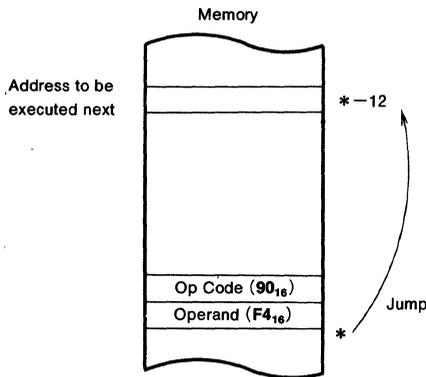

Function : Branching occurs to the address specified by the value resulting from addition of the contents of the program counter and the instruction's second byte. In the case of a long branch by the BRA instruction, a 15-bit signed numeric value formed by the contents of the instruction's second and third bytes is added to the program counter contents. If the addition generates a carry or borrow, 1 is added to or subtracted from the program bank register.

Instruction : **BCC, BCS, BEQ, BMI, BNE, BPL, BRA, BVC, BVS**

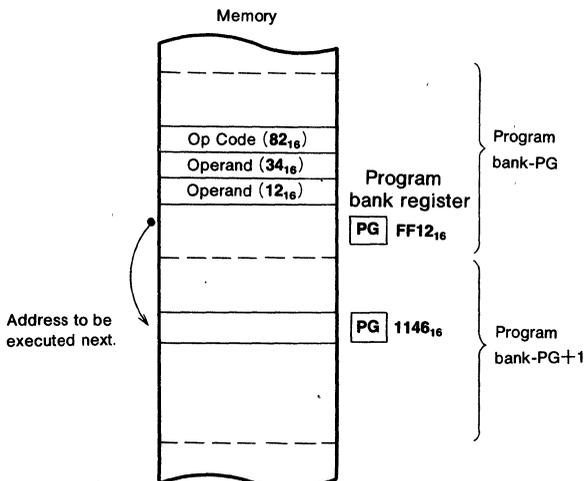

ex. : Mnemonic **BCC * -12** Machine code **90₁₆ F4₁₆**

Branches to the address * -12 if the carry flag (C) has been cleared

Advances to the address * if the carry flag (C) has been set.

 (m=0)

MITSUBISHI MICROCOMPUTERS SERIES MELPS 7700 ADDRESSING MODES

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

Mode : Stack pointer relative indirect indexed Y addressing mode

Function : The value obtained by adding the instruction's second byte and the contents of the stack pointer specifies 2 adjacent bytes in memory. The value obtained by adding the contents of these bytes and the contents of the index register Y specifies address of the actual data in memory bank-DT (DT is contents of data bank register). If addition of the 2 bytes in memory with the contents of the index register Y generate a carry, the bank number will be 1 larger than the contents of the data bank register.

Instruction : **ADC, AND, CMP, DIV, EOR, LDA, MPY, ORA, SBC, STA**

ex. : Mnemonic **ADC A,(1EH, S), Y** Machine code **73₁₆ 1E₁₆**
(m=1, x=1)

ex. : Mnemonic **ADC A,(1EH, S), Y** Machine code **73₁₆ 1E₁₆**
(m=0, x=1)

MITSUBISHI MICROCOMPUTERS SERIES MELPS 7700 ADDRESSING MODES

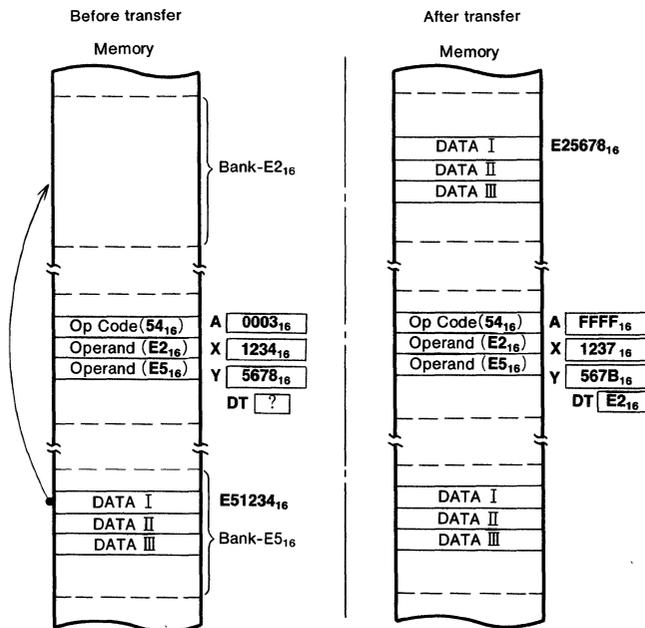

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

Mode : Block transfer addressing mode

Function : The instruction's second byte specifies the transfer-to data bank, and the contents of the index register Y specify the transfer-to address within the data bank. The instruction's third byte specifies the transfer-from data bank, and the contents of the index register X specify the address in the data bank where the data to be transferred is stored. The contents of the accumulator A constitute the number of bytes to be transferred. Upon termination of transfer, the contents of the data bank register will specify the transfer-to data bank. The MVN instruction is used for transfer to lower address location. In this case, the contents of the index registers X and Y are incremented each time data is transferred. The MVP instruction is used for transfer to higher address location. In this case, the contents of the index registers X and Y are decremented each time data is transferred. The block of data to be transferred may cross over the bank boundary.

Instruction : MVN, MVP

ex. : Mnemonic Machine code
MVN 0E2H, 0E5H **54₁₆ E2₁₆ E5₁₆**

MITSUBISHI MICROCOMPUTERS

SERIES MELPS 7700 MACHINE INSTRUCTIONS

The number of cycles shown in the table is described in case of the fastest mode for each instruction. The number of cycles shown in the table is calculated for $DPR_L=0$. The number of cycles in the addressing mode concerning the DPR when $DPR_L \neq 0$ must be incremented by 1. The number of cycles shown in the table differs according to the bytes fetched into the instruction queue buffer, or according to whether the memory read/write address is odd or even. It also differs when the external region memory is accessed by $BYTE="H"$

Note 1. The operation code at the upper row is used for accumulator A, and the operation at the lower row is used for accumulator B.

Note 2. When setting flag $m=0$ to handle the data as 16-bit data in the immediate addressing mode, the number of bytes increments by 1

Note 3. The number of cycles increments by 2 when branching

Note 4. The operation code on the upper row is used for branching in the range of $-128 \sim +127$, and the operation code on the lower row is used for branching in the range of $-32768 \sim +32767$

Note 5. When handling 16-bit data with flag $m=0$, the byte in the table is incremented by 1

Note 6.

Type of register	A	B	X	Y	DPR	DT	PG	PS
Number of cycles	2	2	2	2	2	1	1	2

The number of cycles corresponding to the register to be pushed are added. The number of cycles when no pushing is done is 12. i_1 indicates the number of registers among A, B, X, Y, DPR, and PS to be saved, while i_2 indicates the number of registers among DT and PG to be saved.

Note 7.

Type of register	A	B	X	Y	DPR	DT	PS
Number of cycles	3	3	3	3	4	3	3

The number of cycles corresponding to the register to be pulled are added. The number of cycles when no pulling is done is 14. i_1 indicates the number of registers among A, B, X, Y, DT, and PS to be restored, while $i_2=1$ when DPR is to be restored.

Note 8. The number of cycles is the case when the number of bytes to be transferred is even.
When the number of bytes to be transferred is odd, the number is calculated as,

$$7 + (i/2) \times 7 + 4$$

Note that, $(i/2)$ shows the integer part when i is divided by 2.

Note 9. The number of cycles is the case when the number of bytes to be transferred is even.
When the number of bytes to be transferred is odd, the number is calculated as,

$$9 + (i/2) \times 7 + 5$$

Note that, $(i/2)$ shows the integer part when i is divided by 2.

Note 10. The number of cycles is the case in the 16-bit \div 8-bit operation. The number of cycles is incremented by 16 for 32-bit \div 16-bit operation.

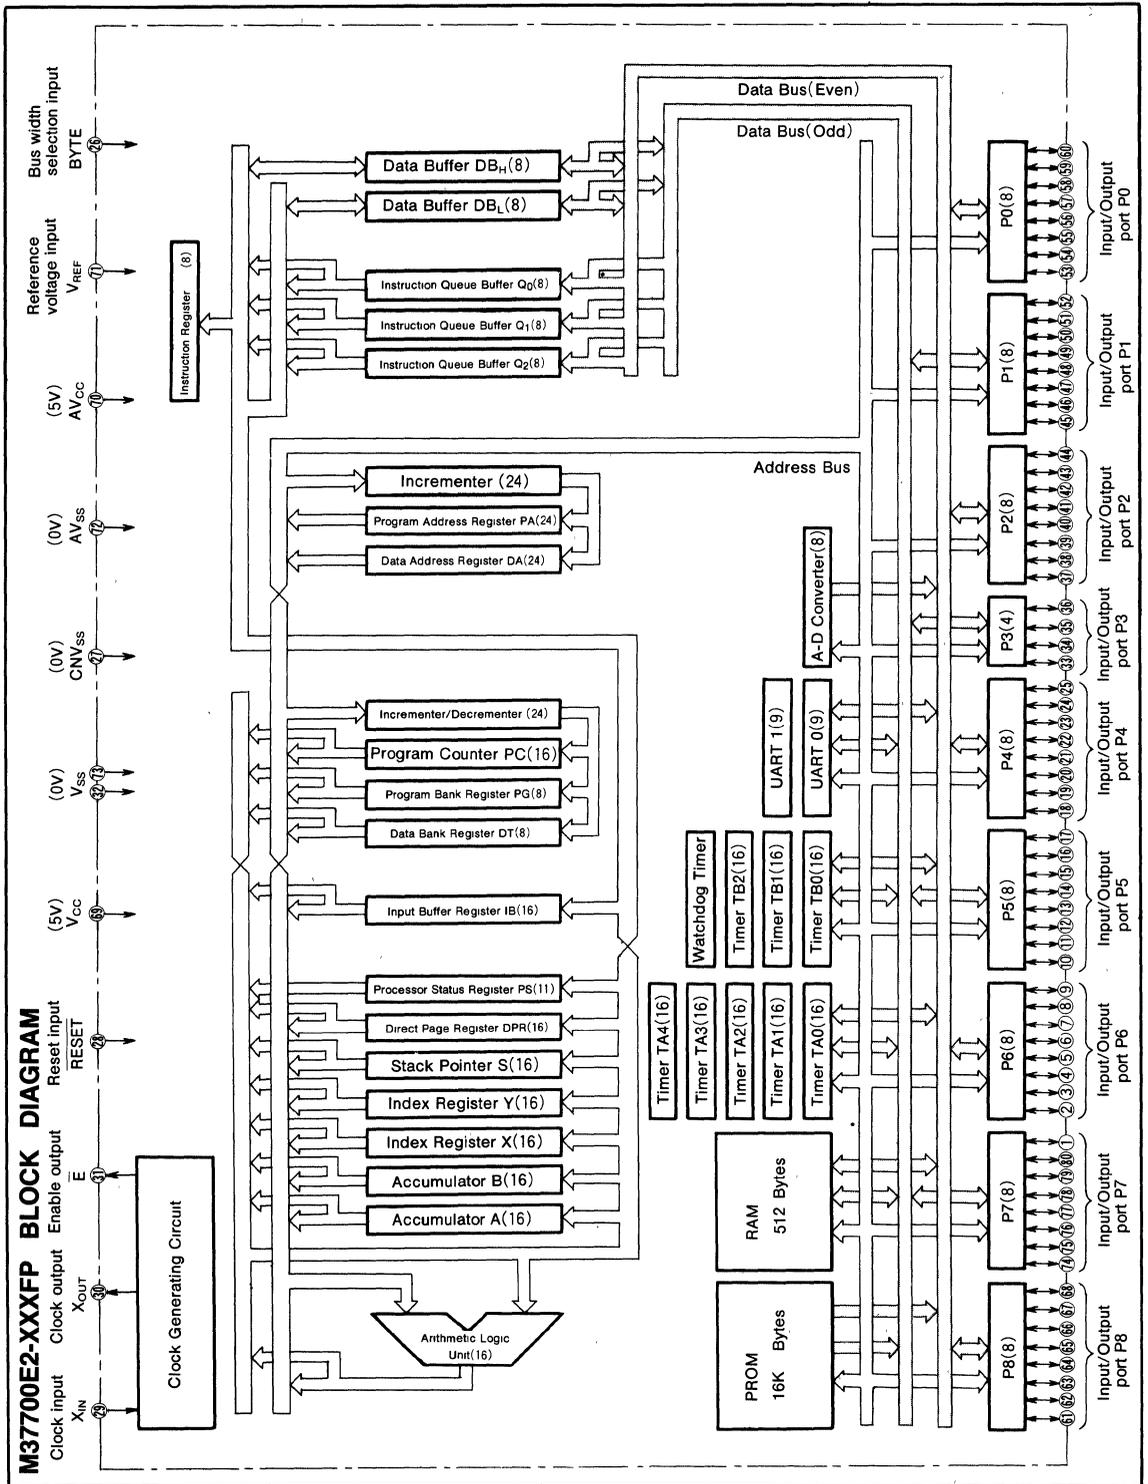

Note 11. The number of cycles is the case in the 8-bit \times 8-bit operation. The number of cycles is incremented by 8 for 16-bit \times 16-bit operation.

Note 12. When setting flag $x=0$ to handle the data as 16-bit data in the immediate addressing mode, the number of bytes increments by 1

Note 13. When flag m is 0, the byte in the table is incremented by 1.

PIN DESCRIPTION (NORMAL MODE)

Pin	Name	Input/Output	Functions
V _{CC} , V _{SS}	Power supply		Supply 5 V ± 5 % to V _{CC} and 0 V to V _{SS}
CNV _{SS}	CNV _{SS} input	Input	This pin controls the processor mode. Connect to V _{SS} for single-chip mode.
RESET	Reset input	Input	To enter the reset state, this pin must be kept at a "L" condition which should be maintained for the required time
X _{IN}	Clock input	Input	These are I/O pins of internal clock generating circuit. Connect a ceramic or quartz crystal resonator between X _{IN} and X _{OUT} . When an external clock is used, the clock source should be connected to the X _{IN} pin and the X _{OUT} pin should be left open.
X _{OUT}	Clock output	Output	
\bar{E}	Enable output	Output	Data or instruction read and data write are performed when output from this pin is "L".
BYTE	Bus width selection input	Input	In memory expansion mode or microprocessor mode, this pin determines whether the external data bus is 8-bit width or 16-bit width. The width is 16 bits when "L" signal inputs and 8 bits when "H" signal inputs.
AV _{CC} , AV _{SS}	Analog supply input		Power supply for the A-D converter. Connect AV _{CC} to V _{CC} and AV _{SS} to V _{SS} externally.
V _{REF}	Reference voltage input	Input	This is reference voltage input pin for the A-D converter.
P0 ₀ ~P0 ₇	I/O port P0	I/O	In single-chip mode, port P0 becomes an 8-bit I/O port. An I/O directional register is available so that each pin can be programmed for input or output. These ports are in input mode when reset. Address(A ₇ ~A ₀) is output in memory expansion mode or microprocessor mode.
P1 ₀ ~P1 ₇	I/O port P1	I/O	In single-chip mode, these pins have the same functions as port P0. When the BYTE pin is set to "L" in memory expansion mode or microprocessor mode and external data bus is 16-bit width, high-order data (D ₁₅ ~D ₈) is input or output when \bar{E} output is "L" and an address (A ₁₅ ~A ₈) is output when \bar{E} output is "H". If the BYTE pin is "H" that is an external data bus is 8-bit width, only address(A ₁₅ ~A ₈) is output.
P2 ₀ ~P2 ₇	I/O port P2	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode low-order data(D ₇ ~D ₀) is input or output when \bar{E} output is "L" and an address(A ₂₃ ~A ₁₆) is output when \bar{E} output is "H".
P3 ₀ ~P3 ₃	I/O port P3	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode, R/W, BHE, ALE, and HLD \bar{A} signals are output.
P4 ₀ ~P4 ₇	I/O port P4	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode, P4 ₀ and P4 ₁ become HOLD and RDY input pin respectively. Functions of other pins are the same as in single-chip mode. Port P4 ₂ can be programmed for ϕ_1 output pin divided the clock to X _{IN} pin by 2.
P5 ₀ ~P5 ₇	I/O port P5	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as I/O pins for timer A0, timer A1, timer A2, and timer A3.
P6 ₀ ~P6 ₇	I/O port P6	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as I/O pins for timer A4, external interrupt input INT $\bar{0}$, INT $\bar{1}$, and INT $\bar{2}$ pins, and input pins for timer B0, timer B1, and timer B2.
P7 ₀ ~P7 ₇	I/O port P7	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as analog input AN ₀ ~AN ₇ input pins. P7 ₇ also has an A-D conversion trigger input function.
P8 ₀ ~P8 ₇	I/O port P8	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as RxD, TxD, CLK, CTS/RTS pins for UART 0 and UART 1.

PROM VERSION of M37700M2-XXXFP, M37700M2AXXFP

EPROM MODE

The M37700E2-XXXFP features an EPROM mode in addition to its normal modes. When the $\overline{\text{RESET}}$ signal level is "L", the chip automatically enters the EPROM mode. Table 1 lists the correspondence between pins and Fig. 2 gives the pin connections in the EPROM mode.

When in the EPROM mode, ports P0, P1, P2, P5₁, P5₂, CNV_{SS} and BYTE are used for the EPROM (equivalent to the M5M27C256K). When in this mode, the built-in PROM can be written to or read from using these pins in the same way as with the M5M27C256K.

This chip does not have Device Identifier Mode, so that set the corresponding program algorithm. The program area should specify address 4000₁₆~7FFF₁₆ for the M37700E2-XXXFP.

Connect the clock which is either ceramic resonator or external clock to X_{IN} pin and X_{OUT} pin.

PIN DESCRIPTION

Pin	Name	Input/Output	Functions
V _{CC} , V _{SS}	Power supply		Supply 5 V± 5% to V _{CC} and 0 V to V _{SS} .
CNV _{SS}	CNV _{SS} input	Input	This pin controls the processor mode. Connect to V _{SS} for single-chip mode.
RESET	Reset input	Input	To enter the reset state, this pin must be kept at a "L" condition should be maintained for the required time.
X _{IN}	Clock input	Input	These are I/O pins of internal clock generating circuit. Connect a ceramic or quartz crystal resonator between X _{IN} and X _{OUT} . When an external clock is used, the clock source should be connected to the X _{IN} pin and the X _{OUT} pin should be left open.
X _{OUT}	Clock output	Output	
\bar{E}	Enable output	Output	Data or instruction read and data write are performed when output from this pin is "L".
BYTE	Bus width selection input	Input	In memory expansion mode or microprocessor mode, this pin determines whether the external data bus is 8-bit width or 16-bit width. The width is 16 bits when "L" signal inputs and 8 bits when "H" signal inputs.
AV _{CC} , AV _{SS}	Analog supply input		Power supply for the A-D converter. Connect AV _{CC} to V _{CC} and AV _{SS} to V _{SS} externally.
V _{REF}	Reference voltage input	Input	This is reference voltage input pin for the A-D converter.
P0 ₀ ~P0 ₇	I/O port P0	I/O	In single-chip mode, port P0 becomes an 8-bit I/O port. An I/O directional register is available so that each pin can be programmed for input or output. These ports are in input mode when reset. Address(A ₇ ~A ₀) is output in memory expansion mode or microprocessor mode.
P1 ₀ ~P1 ₇	I/O port P1	I/O	In single-chip mode, these pins have the same functions as port P0. When the BYTE pin is set to "L" in memory expansion mode or microprocessor mode and external data bus is 16-bit width, high-order data (D ₁₅ ~D ₈) is input or output when \bar{E} output is "L" and an address (A ₁₅ ~A ₈) is output when \bar{E} output is "H". If the BYTE pin is "H" that is an external data bus is 8-bit width, only address(A ₁₅ ~A ₈) is output.
P2 ₀ ~P2 ₇	I/O port P2	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode low-order data(D ₇ ~D ₀) is input or output when \bar{E} output is "L" and an address(A ₂₃ ~A ₁₆) is output when \bar{E} output is "H".
P3 ₀ ~P3 ₂	I/O port P3	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode, R/W, \bar{BHE} , and ALE signals are output.
P4 ₀ ~P4 ₂ , P4 ₇	I/O port P4	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode, P4 ₀ and P4 ₁ become \bar{HOLD} and \bar{RDY} input pin respectively. Functions of other pins are the same as in single-chip mode. Port P4 ₂ can be programmed for ϕ_1 output pin divided the clock to X _{IN} pin by 2.
P5 ₀ ~P5 ₇	I/O port P5	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as I/O pins for timer A0, timer A1, timer A2, and timer A3.
P6 ₂ ~P6 ₅	I/O port P6	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as external interrupt input INT ₀ , INT ₁ , and INT ₂ pins, and input pins for timer B0.
P7 ₀ ~P7 ₂ , P7 ₇	I/O port P7	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as analog input AN ₀ ~AN ₂ and AN ₇ input pins. P7 ₇ also has an A-D conversion trigger input function.
P8 ₀ ~P8 ₃ , P8 ₆ , P8 ₇	I/O port P8	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as RxD, TxD, CLK, CTS/RTS pins for UART 0, and as RxD, TxD pins for UART 1.

MITSUBISHI MICROCOMPUTERS

M37701E2-XXXSP, M37701E2AXXXSP

PROM VERSION of M37701M2-XXXSP, M37701M2AXXXSP

EPROM MODE

The M37701E2-XXXSP features an EPROM mode in addition to its normal modes. When the $\overline{\text{RESET}}$ signal level is "L", the chip automatically enters the EPROM mode. Table 1 list the correspondence between pins and Fig. 1 gives the pin connections in the EPROM mode.

When in the EPROM mode, ports P0, P1, P2, P5₁, P5₂, CNV_{SS} and BYTE are used for the EPROM (equivalent to the M5M27C256K). When in this mode, the built-in PROM can be written to or read from using these pins in the same way as with the M5M27C256K.

This chip does not have Device Identifier Mode, so that set the corresponding program algorithm. The program area should specify address $4000_{16} \sim 7FFF_{16}$ for the M37701E2-

XXXSP.

Connect the clock which is either ceramic resonator or external clock to X_{IN} pin and X_{OUT} pin.

PIN DESCRIPTION (NORMAL MODE)

Pin	Name	Input/Output	Functions
V _{CC} , V _{SS}	Power supply		Supply 5 V±5% to V _{CC} and 0 V to V _{SS}
CNV _{SS}	CNV _{SS} input	Input	This pin controls the processor mode. Connect to V _{SS} for single-chip mode.
RESET	Reset input	Input	To enter the reset state, this pin must be kept at a "L" condition which should be maintained for the required time.
X _{IN}	Clock input	Input	These are I/O pins of internal clock generating circuit. Connect a ceramic or quartz crystal resonator between X _{IN} and X _{OUT} . When an external clock is used, the clock source should be connected to the X _{IN} pin and the X _{OUT} pin should be left open.
X _{OUT}	Clock output	Output	
\bar{E}	Enable output	Output	Data or instruction read and data write are performed when output from this pin is "L".
BYTE	Bus width selection input	Input	In memory expansion mode or microprocessor mode, this pin determines whether the external data bus is 8-bit width or 16-bit width. The width is 16 bits when "L" signal inputs and 8 bits when "H" signal inputs.
AV _{CC} , AV _{SS}	Analog supply input		Power supply for the A-D converter. Connect AV _{CC} to V _{CC} and AV _{SS} to V _{SS} externally.
V _{REF}	Reference voltage input	Input	This is reference voltage input pin for the A-D converter.
P0 ₀ ~P0 ₇	I/O port P0	I/O	In single-chip mode, port P0 becomes an 8-bit I/O port. An I/O directional register is available so that each pin can be programmed for input or output. These ports are in input mode when reset. Address(A ₇ ~A ₀) is output in memory expansion mode or microprocessor mode.
P1 ₀ ~P1 ₇	I/O port P1	I/O	In single-chip mode, these pins have the same functions as port P0. When the BYTE pin is set to "L" in memory expansion mode or microprocessor mode and external data bus is 16-bit width, high-order data (D ₁₅ ~D ₈) is input or output when \bar{E} output is "L" and an address (A ₁₅ ~A ₈) is output when \bar{E} output is "H". If the BYTE pin is "H" that is an external data bus is 8-bit width, only address(A ₁₅ ~A ₈) is output.
P2 ₀ ~P2 ₇	I/O port P2	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode low-order data(D ₇ ~D ₀) is input or output when \bar{E} output is "L" and an address(A ₂₃ ~A ₁₆) is output when \bar{E} output is "H".
P3 ₀ ~P3 ₃	I/O port P3	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode, R/W, BHE, ALE, and HLDA signals are output.
P4 ₀ ~P4 ₇	I/O port P4	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode, P4 ₀ and P4 ₁ become HOLD and \bar{RDY} input pin respectively. Functions of other pins are the same as in single-chip mode. In single-chip mode or memory expansion mode, port P4 ₂ can be programmed for ϕ_1 output pin divided the clock to X _{IN} pin by 2. In microprocessor mode, P4 ₂ always has the function as ϕ_1 output pin.
P5 ₀ ~P5 ₇	I/O port P5	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as I/O pins for timer A0, timer A1, timer A2, and timer A3. P5 ₀ to P5 ₆ also have the function as motor control output pins.
P6 ₀ ~P6 ₇	I/O port P6	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as I/O pins for timer A4, external interrupt input INT ₀ , INT ₁ , and INT ₂ pins, and input pins for timer B0, timer B1, and timer B2. P6 ₀ and P6 ₂ also have the function as motor control output pins.
P7 ₀ ~P7 ₇	I/O port P7	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as analog input AN ₀ ~AN ₇ input pins. P7 ₇ also has an A-D conversion trigger input function.
P8 ₀ ~P8 ₇	I/O port P8	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as RxD, TxD, CLK, CTS/RTS pins for UART 0 and UART 1.

PROM VERSION of M37704M2-XXXFP, M37704M2AXXXFP

EPROM MODE

The M37704E2-XXXFP features an EPROM mode in addition to its normal modes. When the $\overline{\text{RESET}}$ signal level is "L", the chip automatically enters the EPROM mode. Table 1 list the correspondence between pins and Fig. 1 gives the pin connections in the EPROM mode.

When in the EPROM mode, ports P0, P1, P2, P5₁, P5₂, CNV_{SS} and BYTE are used for the EPROM (equivalent to the M5M27C256K). When in this mode, the built-in PROM can be written to or read from using these pins in the same way as with the M5M27C256K.

This chip does not have Device Identifier Mode, so that set the corresponding program algorithm. The program area should specify address 4000₁₆ ~ 7FFF₁₆ for the M37704E2-XXXFP.

Set the clock which is either ceramic resonator or external clock to X_{IN} pin and X_{OUT} pin.

PIN DESCRIPTION

Pin	Name	Input/Output	Functions
V _{CC} , V _{SS}	Power supply		Supply 5 V ± 5 % to V _{CC} and 0 V to V _{SS}
CNV _{SS}	CNV _{SS} input	Input	This pin controls the processor mode. Connect to V _{SS} for single-chip mode.
RESET	Reset input	Input	To enter the reset state, this pin must be kept at a "L" condition should be maintained for the required time.
X _{IN}	Clock input	Input	These are I/O pins of internal clock generating circuit. Connect a ceramic or quartz crystal resonator between X _{IN} and X _{OUT} . When an external clock is used, the clock source should be connected to the X _{IN} pin and the X _{OUT} pin should be left open.
X _{OUT}	Clock output	Output	
\bar{E}	Enable output	Output	Data or instruction read and data write are performed when output from this pin is "L".
BYTE	Bus width selection input	Input	In memory expansion mode or microprocessor mode, this pin determines whether the external data bus is 8-bit width or 16-bit width. The width is 16 bits when "L" signal inputs and 8 bits when "H" signal inputs.
AV _{CC} , AV _{SS}	Analog supply input		Power supply for the A-D converter. Connect AV _{CC} to V _{CC} and AV _{SS} to V _{SS} externally.
V _{REF}	Reference voltage input	Input	This is reference voltage input pin for the A-D converter.
P0 ₀ ~P0 ₇	I/O port P0	I/O	In single-chip mode, port P0 becomes an 8-bit I/O port. An I/O directional register is available so that each pin can be programmed for input or output. These ports are in input mode when reset Address(A ₇ ~A ₀) is output in memory expansion mode or microprocessor mode.
P1 ₀ ~P1 ₇	I/O port P1	I/O	In single-chip mode, these pins have the same functions as port P0. When the BYTE pin is set to "L" in memory expansion mode or microprocessor mode and external data bus is 16-bit width, high-order data (D ₁₅ ~D ₈) is input or output when \bar{E} output is "L" and an address (A ₁₅ ~A ₈) is output when \bar{E} output is "H". If the BYTE pin is "H" that is an external data bus is 8-bit width, only address(A ₁₅ ~A ₈) is output.
P2 ₀ ~P2 ₇	I/O port P2	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode low-order data(D ₇ ~D ₀) is input or output when \bar{E} output is "L" and an address(A ₂₃ ~A ₁₆) is output when \bar{E} output is "H".
P3 ₀ ~P3 ₂	I/O port P3	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode, R/W, BHE, and ALE signals are output.
P4 ₀ ~P4 ₂ , P4 ₇	I/O port P4	I/O	In single-chip mode, these pins have the same functions as port P0. In memory expansion mode or microprocessor mode, P4 ₀ and P4 ₁ become HOLD and RDY input pin respectively. Functions of other pins are the same as in single-chip mode. In single-chip mode or memory expansion mode, port P4 ₂ can be programmed for ϕ_1 output pin divided the clock to X _{IN} pin by 2. In microprocessor mode, P4 ₂ always has the function as ϕ_1 output pin.
P5 ₀ ~P5 ₆	I/O port P5	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as I/O pins for timer A0, timer A1, timer A2, and output pin for timer A3. These pins also have the function as motor control output pin.
P6 ₀ , P6 ₂ , P6 ₃ , P6 ₅ , P6 ₆	I/O port P6	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as output pins for timer A4, and input pins for external interrupt input INT ₀ and INT ₁ pins, and for timer B0 and timer B1. P6 ₀ and P6 ₂ also have the function as motor control output pins.
P7 ₀ ~P7 ₇	I/O port P7	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as analog input AN ₀ ~AN ₇ input pins. P7 ₇ also has an A-D conversion trigger input function.
P8 ₆ , P8 ₇	I/O port P8	I/O	In addition to having the same functions as port P0 in single-chip mode, these pins also function as RxD and TxD pins for UART 1.

PROM VERSION of M37705M2-XXXSP, M37705M2AXXXSP

EPROM MODE

The M37705E2-XXXSP features an EPROM mode in addition to its normal modes. When the RESET signal level is "L", the chip automatically enters the EPROM mode. Table 1 list the correspondence between pins and Fig. 1 gives the pin connections in the EPROM mode.

When in the EPROM mode, ports P0, P1, P2, P5₁, P5₂, CNV_{SS} and BYTE are used for the EPROM (equivalent to the M5M27C256K). When in this mode, the built-in PROM can be written to or read from using these pins in the same way as with the M5M27C256K.

This chip does not have Device Identifier Mode, so that set the corresponding program algorithm. The program area should specify address 4000₁₆~7FFF₁₆ for the M37705E2-XXXSP.

Connect the clock which is either ceramic resonator or external clock to X_{IN} pin and X_{OUT} pin.

Table 1 Pin function in EPROM programming mode

	M37705E2-XXXSP	M5M27C256K
V _{CC}	V _{CC}	V _{CC}
V _{PP}	CNV _{SS} , BYTE	V _{PP}

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

PIN DESCRIPTION (1)

Pin	Name	Input/ Output	Functions
V _{CC} , V _{DD} , V _{SS}	Power supply		Supply 5V ±10% to V _{CC} , V _{DD} and 0V to V _{SS} .
$\overline{\text{RESET}}$	Reset input	Input	To enter the reset state, this pin must be kept at a "L" condition should be maintained for the required time.
X _{IN}	Clock input	Input	These are I/O pins of internal clock generating circuit. Connect a ceramic or quartz crystal resonator between X _{IN} and X _{OUT} . When an external clock is used, the clock source should be connected to the X _{IN} pin and the X _{OUT} pin should be left open.
X _{OUT}	Clock output	Output	
NUA	NUA input	Input	These pins change processor mode. Connect both pins to V _{SS} in single-chip mode.
NUB	NUB input	Input	
$\overline{\text{E}}$	Enable output	Output	Data or instruction read and data write are performed when output from this pin is "L".
BYTE	Bus width selection input	Input	This pin determines whether the external data bus is 8-bit width or 16-bit width. The width is 16-bit width when "L" signal inputs and 8-bit when "H" signal inputs.
NMI	Non-maskable interrupt input pin	Input	This is the non-maskable interrupt input pin. Connect with GND as this pin is not usually used.
INT	Interrupt input	Input	This pin is interrupt input pin which can use edge or level.
AV _{CC} AV _{SS}	A-D power supply		Power supply for the A-D converter.
V _{REF}	Reference voltage input	Input	This is reference voltage input pin for A-D converter.
P0~P07	I/O port P0	I/O	In single-chip mode, port P0 is 8-bit CMOS input/output port. Each pin can be programmed for input or output pin by the direction register.
D ₀ /A ₀ ~D ₇ /A ₇ (P0~P07)	Data (low-order) / Address bus (low-order)	I/O	In the other mode except for single chip-mode, Multiplex signal consisting of low-order 8-bit of data bus and address bus is input/output.
P1~P17	I/O port P1	I/O	In single-chip mode, port P1 is 8-bit CMOS input/output same as port P0.
D ₈ /A ₈ ~D ₁₅ /A ₁₅ (P1~P17)	Data (high-order) / Address bus (middle-order)	I/O	In the other mode except for single chip-mode, Multiplex signal consisting of high-order 8-bit of data bus and middle-order 8-bit address bus is input/output.
P2~P27	I/O port P2	I/O	In single-chip mode, port P2 is 8-bit CMOS input/output same as port P0.
A ₁₆ ~A ₂₃ (P2~P27)	Address bus (high-order)	Output	In memory expansion mode and microprocessor mode, 8-bit high-order address are output.
WEMP0(P2 ₀) REMP0(P2 ₁) WEMP1(P2 ₂) REMP1(P2 ₃) WEMP2(P2 ₄) REMP2(P2 ₅) WEMP3(P2 ₆) REMP3(P2 ₇)	Emulation strobe signal	Output	In port emulation mode, these pins are strobe signal output pins which indicates writing or reading to port P0~P3 with "H" level.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER

PIN DESCRIPTION (PROM MODE)

Pin	Name	Input/Output	Functions
V _{CC} , V _{DD} , V _{SS}	Power supply		Supply 5 V ± 5 % to V _{CC} , V _{DD} and 0 V to V _{SS} .
INT	V _{PP} input	Input	Connect to V _{PP} when programming or verifying
BYTE	V _{PP} input	Input	Connect to V _{PP} when programming or verifying.
<u>RESET</u>	Reset input	Input	Connect to V _{SS} .
X _{IN}	Clock input	Input	Connect a ceramic resonator between X _{IN} and X _{OUT} .
X _{OUT}	Clock output	Output	
<u>E</u>	Enable output	Output	Keep open.
AV _{CC} , AV _{SS}	A-D power supply	Input	Connect AV _{CC} to V _{CC} , and AV _{SS} to V _{SS} .
V _{REF}	Reference voltage input	Input	Connect to V _{SS}
P0 ₀ ~P0 ₇	Data I/O (D ₀ ~D ₇)	I/O	Port P0 functions as the 8 bits data bus (D ₀ ~D ₇)
P1 ₀ ~P1 ₇	Address input (A ₈ ~A ₁₄)	Input	Port P1 ₀ ~P1 ₆ functions as the higher 7 bits address input (A ₈ ~A ₁₄). Connect P1 ₇ to V _{CC} .
P2 ₀ ~P2 ₇	Address input (A ₀ ~A ₇)	Input	Port P2 functions as the lower 8 bits address input (A ₀ ~A ₇).
P3 ₀ ~P3 ₃	Input port P3	Input	Connect to V _{SS} .
P4 ₀ ~P4 ₇	Input port P4	Input	Connect P4 ₃ and P4 ₅ to V _{CC} , and P4 ₀ ~P4 ₂ , P4 ₄ and P4 ₆ to V _{SS} . Keep P4 ₇ open.
P5 ₀ ~P5 ₇	Control signal input	Input	P5 ₁ and P5 ₂ function as <u>OE</u> and <u>CE</u> input pin Connect P5 ₀ , P5 ₃ , P5 ₄ , P5 ₅ and P5 ₇ to V _{CC} . Connect P5 ₆ to V _{SS} .
P6 ₀ ~P6 ₇	Input port P6	Input	Connect to V _{SS} .
P7 ₀ ~P7 ₇	Input port P7	Input	Connect to V _{SS} .
AN ₀ ~AN ₇	Input port P8	Input	Connect to V _{SS} .
NMI		Input	Connect to V _{SS} .
NUA, NUB		Input	Connect to V _{SS} .

M37796E4-XXXJ TIMER SYSTEM BLOCK DIAGRAM

SAFETY INSTRUCTIONS

The programmable M37796E4J and M37796E4TJ that are shipped in blank are also provided. For the M37796E4J and M37796E4TJ, Mitsubishi Electric corp. does not perform PROM write test and screening in the assembly process and following processes. To improve reliability after write, performing write and test according to the flow below before use is recommended.

ADDRESSING MODES

The M37796E4-XXXJ has 28 powerful addressing modes. Refer to the Series MELPS 7700 addressing mode description for the details of each addressing mode.

MACHINE INSTRUCTION LIST

The M37796E4-XXXJ has 103 machine instructions. Refer to the Series MELPS 7700 machine instruction list for details.

DATA REQUIRED FOR PROM ORDERING

Please send the following data for writing to PROM.

- (1) M37796E4-XXXJ writing to PROM order confirmation form
- (2) Mark specification form for 84P0
- (3) ROM data (EPROM 3 sets)

- Note 4 If \bar{BHE} is fixed to V_{IH}, Non-ALE mode is enabled, and if ALE is fixed to V_{IH}, address inputs of D₀/A₁₆ and D₁/A₁₇ are not needed

(3) Counter

The input pulse from C_{IN} pin is counted by an 8-bit up-counter. The count value can be preset or output from data pins D_0 to D_7 .

Table 3 shows the table for counter mode.

Initial setting for counter use

C_{IN}/PD_3 , C_{OUT}/PD_4 , CLK/PD_5 are common function pins related to a counter. Port PD should be specified to enable counter pin for counter use. This can be specified by writing "H" to data pin D_7 after the address $0480E_{16}$ is specified. Then clock pulse should be continuously input from CLK pin. The counter operation is synchronized with this clock pulse.

(Prescaler mode)

This mode is enabled by an 8-bit prescaler counter (C_0) to count the input pulse from C_{IN} pin and by an 8-bit counter (C_1) to count the overflow output pulse. Each counter returns to the preset count value by the overflow output pulse to count up again.

Table 4 Mode setting and counter preset

Parameter	Write address	Write data
Mode setting (counter mode and edge mode)	$0480C_{16}$	See Table 3.
C_0 counter preset	04808_{16}	Any preset value from 00 to FF
C_1 counter preset	$0480A_{16}$	Any preset value from 00 to FF

Table 3 Counter mode table

Counter mode register ($0480C_{16}$)			Mode name		Counter configuration
D_7	D_5	D_4	Counter mode	Edge mode	
0	0	0	Prescaler mode	Count disable mode	See Fig 2. • Counter is preset by the OVF output timing
	0	1		Falling edge count mode	
	1	0		Rising edge count mode	
	1	1		Double edge count mode	
1	0	0	Double count mode	Count disable mode	See Fig 3 • Counter is preset by the external trigger timing
	0	1		Falling edge count mode	
	1	0		Rising edge count mode	
	1	1		Double edge count mode	

(Double count mode)

In this mode, both C_0 counter and C_1 counter count the input pulse from C_{IN} pin. C_0 counter is preset by the trigger input from $PC_7/TRIG$ pin and C_1 counter is preset by the overflow output pulse of C_0 counter.

To enable the double count mode, $PC_7/TRIG$ pin should be initialized as TRIG pin by specifying the address 04804_{16} and by writing "L" to D_7 pin.

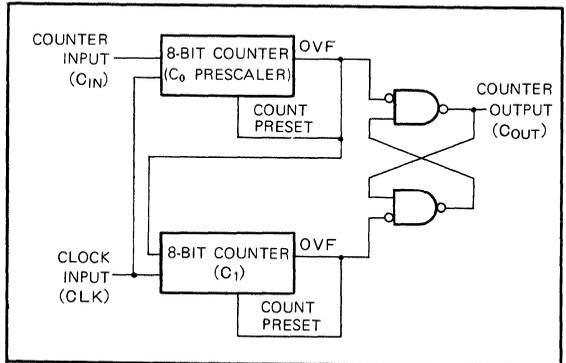

Fig. 2 Prescaler mode

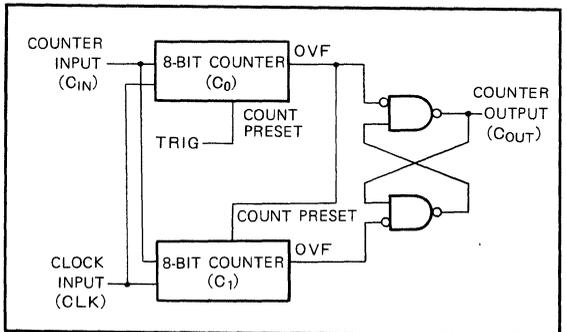

Fig. 3 Double count mode

ABSOLUTE MAXIMUM RATINGS

CONSTRUCTION

The following shows the software construction of RASM77.

Relocatable macro assembler RASM77	Assembles the assembly language source files for series MELSP 7700, and generates the relocatable object files.
Linkage editor LINK77	Generates a machine language file in hexadecimal format from the plural relocatable files generated by RASM77.
Librarian LIB77	Generates a library file from the relocatable files generated by RASM77
Cross referencer CRF77	Generates a cross reference file from the assembly language source files for series MELPS 7700 The cross reference file shows the points defined, and referenced the labels and symbols.
File converter HEXTOS2	Generates a S format machine language file from a hexadecimal format machine language file generated LINK77

ENVIRONMENT

RASM77 operates in the following OS environments.

- MS-DOS
- SUN-3/SUN OS
- VAX/ULTRIX
- HP9000/HP-UX

Note 1 : MS-DOS is a registered trademark of Microsoft Corp.

Note 2 : SUN-3 and SUN OS are registered trademarks of Sun Microsystems Corp.

Note 3 : VAX and ULTRIX are registered trademarks of Digital Equipment Corp.

Note 4 : HP9000 and HP-UX are registered trademarks of HEWLETT PACKARD Corp.

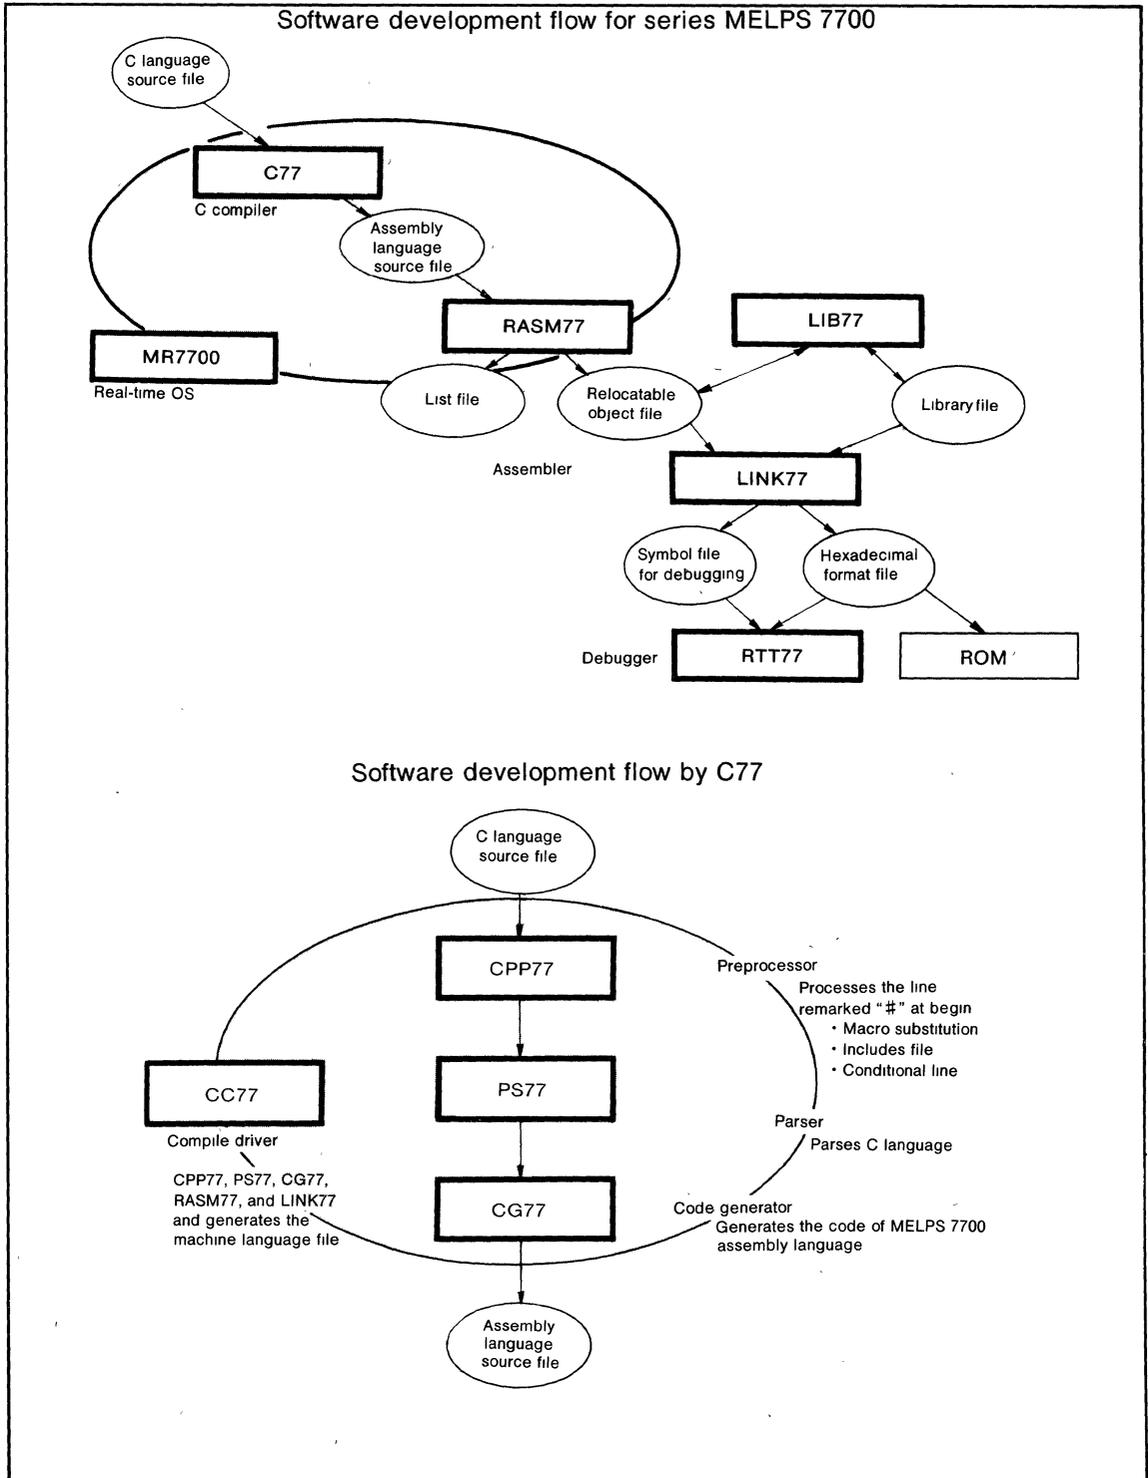

Fig. 1 C77 processing flow

DESCRIPTION

SDB77 is the series MELPS 7700 debugger control software prepared for the PC4816 system. SDB77 operates on a 16-bit personal computer that supports the MS-DOS environment, and controls the PC4816 system through the RS-232C serial interface.

DISTINCTIVE FEATURES

SDB77 supports the following features:

- Support of the runtime debugging function that refers memory during execution of a program
- Support of various break point setting functions
- Support of various real-time trace control functions
- Support of the execution time measurement function
- Support of the C language source line display function
- Apply to every MCU in the series MELPS 7700 with the use of data files that contain particular data of individual MCU
- The initialization file automatically sets debugging start conditions.
- The batch command enables continuous execution of debugging commands.
- Debugging history can be recorded in the log file.
- Support of the debugging information definition file that automatically sets break points and trace points.
- Support of the online manual

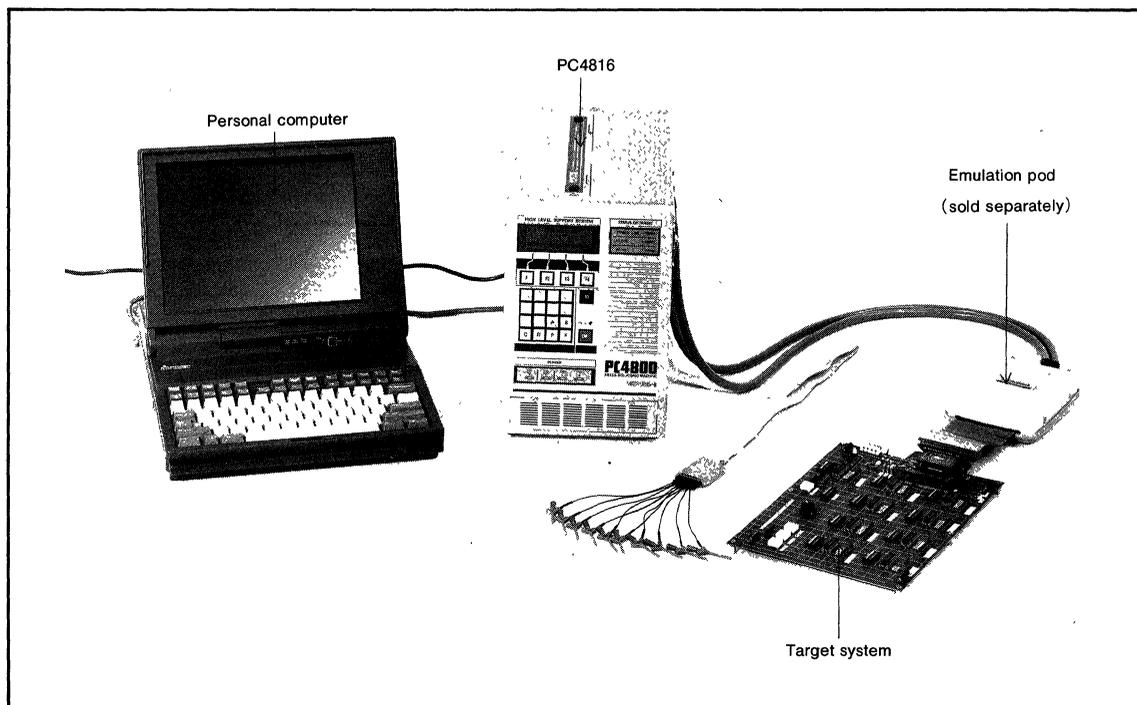

Fig. 1 MELPS 7700 debugger control system

MELPS 7700 REAL-TIME OS DEVELOPMENT KIT

DESCRIPTION

MR7700 is the real-time operating system developed for the 16-bit single-chip microcomputer MELPS 7700 series. MR7700KIT is the tool kit required to develop application software incorporating MR7700.

DISTINCTIVE FEATURES

- Based on with μ ITRON specifications
- Real-time operating system intended for industrial incorporation systems.
- High speed processing
- Minimum size of OS kernel by automatically selecting only necessary modules
- Application programs can be developed in C language by using C compiler C77.

FUNCTIONS

(1) Outline specifications of MR7700

Table 1 shows outline specifications of MR7700.

Table 1 Outline specifications of MR7700

Item	Specifications
Target MCU	Series MELPS 7700
Maximum number of tasks	124
Priority number	1~63
Number of system calls	51
OS nucleus code size	About 0.9K bytes to 5.8K bytes (standard model)
OS nucleus data size	Minimum 14 bytes and 9 bytes increased by each task
OS nucleus description language	Assembly
Task switching time	About 30 μ s max
Maximum interrupt inhibited time	About 11 μ s to 24 μ s

The OS nucleus data size does not include stack size.

Because the 16 bytes of task context (for standard model) is allocated on the stack, contexts of individual tasks are not included in the OS data size.

Time data in the table is measured by M37700M2 (16MHz) at 0 wait memory access and 16-bit width. The task switching time and maximum interrupt inhibited time are for a wup-*tsk* system call at priority number 1.

(2) Kernel configuration for MR7700

The MR7700 kernel consists of two module groups: One is the requisite module group that performs real-time processing and multi-tasking, the other is the expansion function module group from which modules can be selected according to user applications.

Figure 1 shows the module configuration of the MR7700 kernel. The application program is prepared by the user, and is composed of tasks, an interrupt processing handler, a cycle execution handler, and an alarm handler.

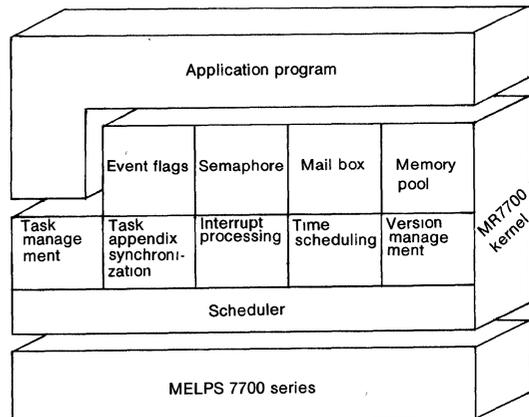

Fig. 1 MR7700 configuration

MR7700SRC**MELPS 7700 REAL-TIME OS SOURCE KIT****DESCRIPTION**

MR7700 is the real-time operating system developed for the 16-bit one-chip microcomputer MELPS 7700 series.

MR7700SRC is the mass production contract that authorizes mass production of products incorporating MR7700.

CONFIGURATION

MR7700SRC consists of the followings elements:

- MR7700 source
- Mass production right (to incorporate MR7700 into an unlimited number of products of a single model)

CONTRACT OUTLIVE

MR7700SRC is the license to manufacture a large quantity of products that incorporate MR7700. This license authorizes production of an unlimited number of products by five specified computer systems and five engineers in a single section. No royalties are charged nor report of output is required. To carry out development by employing more engineers or more systems than specified, the user must acquire the right of use.

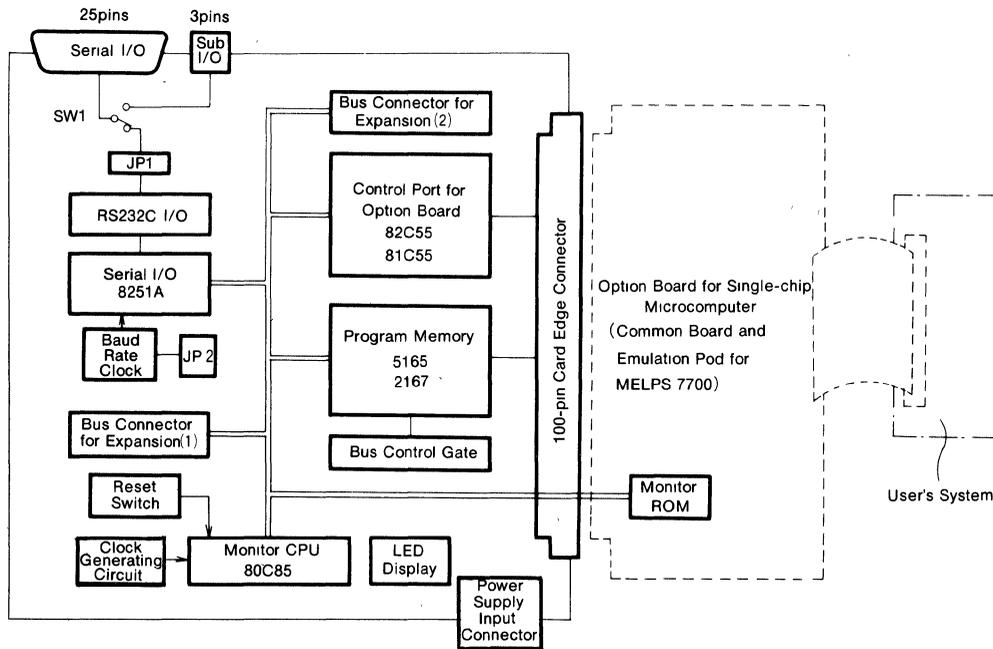

MR7700SRC guarantees maintenance (including software version up) of MR7700 for two years without payment.

NOTES

Purchase of MR7700KIT (development kit) is the prerequisite to close contract MR7700SRC.

- MELPS is a registered trademark of Mitsubishi Electric Corp.

PC4000E BLOCK DIAGRAM

DESCRIPTION

PC4816 is the high performance debugging machine for Mitsubishi original 16-bit microcomputers.

PC4816 executes debugging with a help of emulation pods connected to it. Various emulation pods are prepared for individual microcomputers and provided separately.

PC4816 can be connected to a host machine with a personal computer (hereafter, PC), and can be controlled by control software on the host machine.

Because PC4816 supports simple I/O functions, it can be used as a stand-alone unit after down-load the user's program.

APPLICATIONS

For development of hardware and software for systems using MELPS 7700, and for program debugging.

DISTINCTIVE FEATURES

- Runtime debugging function is supported.
- Program evaluation function is supported.
- Usable as a stand-alone unit.
- Evaluation functions can be enhanced by adding boards.
- Compact design requires less space on a desk.

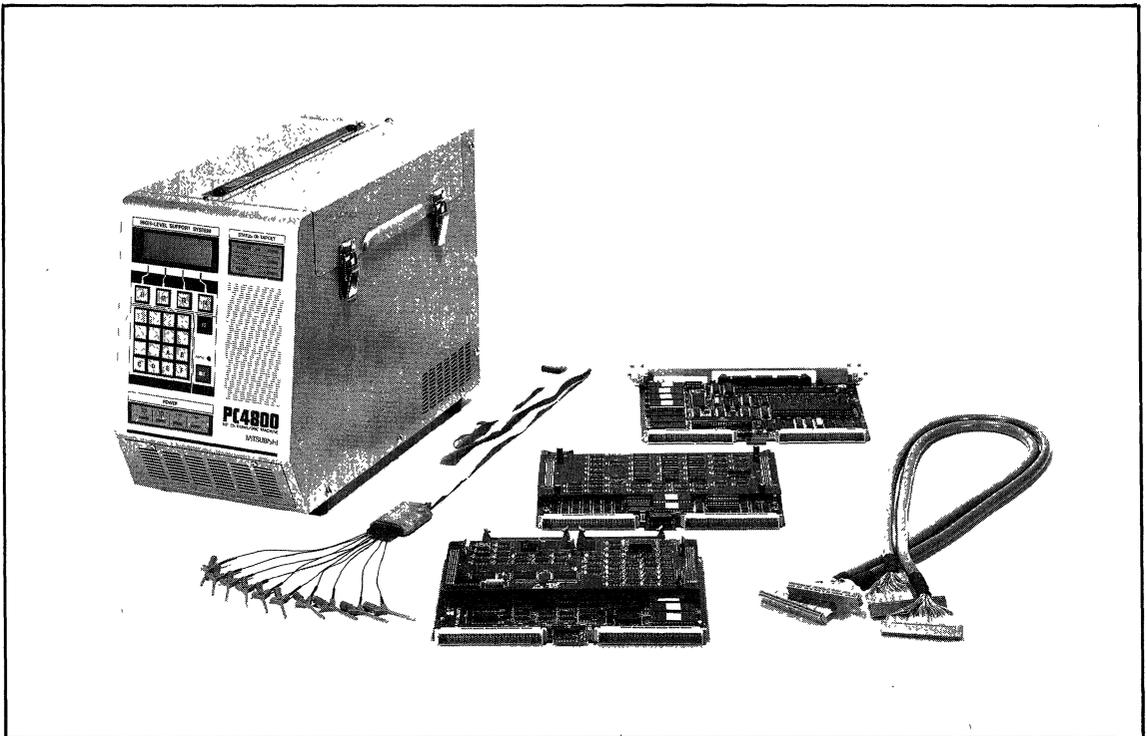

Fig. 1 The exterior of PC4816

MELPS 7700 DEBUGGING MACHINE

FUNCTIONS

PC4816 consists of the following three kind products:

- PC4800

This is the debugger that incorporates the power unit, interface with the host machine, key entry unit, LCD display unit, monitor CPU board, emulation board, and container rack.

- M37700T-CNT

This is the emulation control board that consists of the MCU execution control circuit and program memory.

- PCA4800R

This is the debugging function board that consists of the real-time tracer and coverage function circuit.

PC4816 is used combined with emulation pods that are prepared for individual MCU and provided separately.

PC4800 is connected to the host machine via a serial circuit (RS-232C). PC4816 is connected to the emulation board and the debugging function board via two 96-pin connectors.

When PC4816 is turned on, the monitor CPU is activated and the monitor programs stored in the EPROM on various boards in the rack are started.

When the monitor programs are started, the start message is displayed on the LCD display unit on PC4816. Then the system waits for control instructions from debugger control software SDB77 on the host machine.

When the debugger control software is started, the host machine requests details (board configuration, monitor program version number, etc.) to be reported via the serial circuit. Acceptance of various debugging commands is enabled after PC4816 returns the details correctly.

- Serial circuits : Complying with RS-232C, two circuits
- Parallel circuit : Complying with GP-IB
- Power supply : Power units applicable to 115V and 220V systems
- Board rack : Five boards can be accommodated.

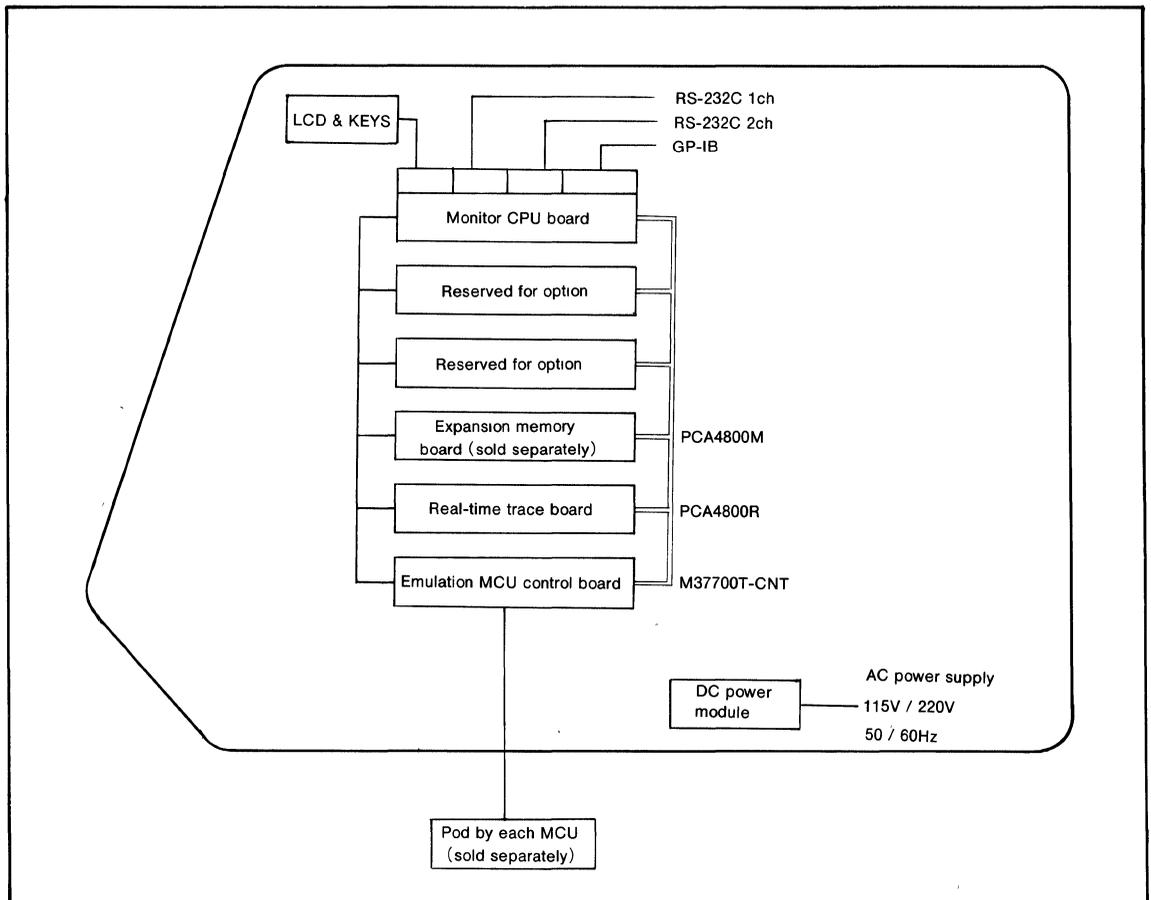

Fig. 3 Functional block diagram

MITSUBISHI MICROCOMPUTERS
PCA4800M

1M BYTE MEMORY EXPANSION BOARD for PC4816

DESCRIPTION

PCA4800M is the emulation memory expansion board that is used incorporated in PC4816, the debugging machine for MELPS 7700.

1M bytes of high speed SRAM, which can be distributed over areas of 16M bytes in units of 4K bytes in mounted.

DISTINCTIVE FEATURES

- Applicable to 8 or 16-bit wide memory buses.

SPECIFICATIONS

Item	Contents
Debugger	PC4816
Corresponding MCU	MELPS 7700 series
Corresponding control board	M37700T-CNT
Corresponding bus width	8, 16-bit
Memory capacity	1MB
Mapping units	4KB
Supply voltage	5 [V] ± 5 [%]

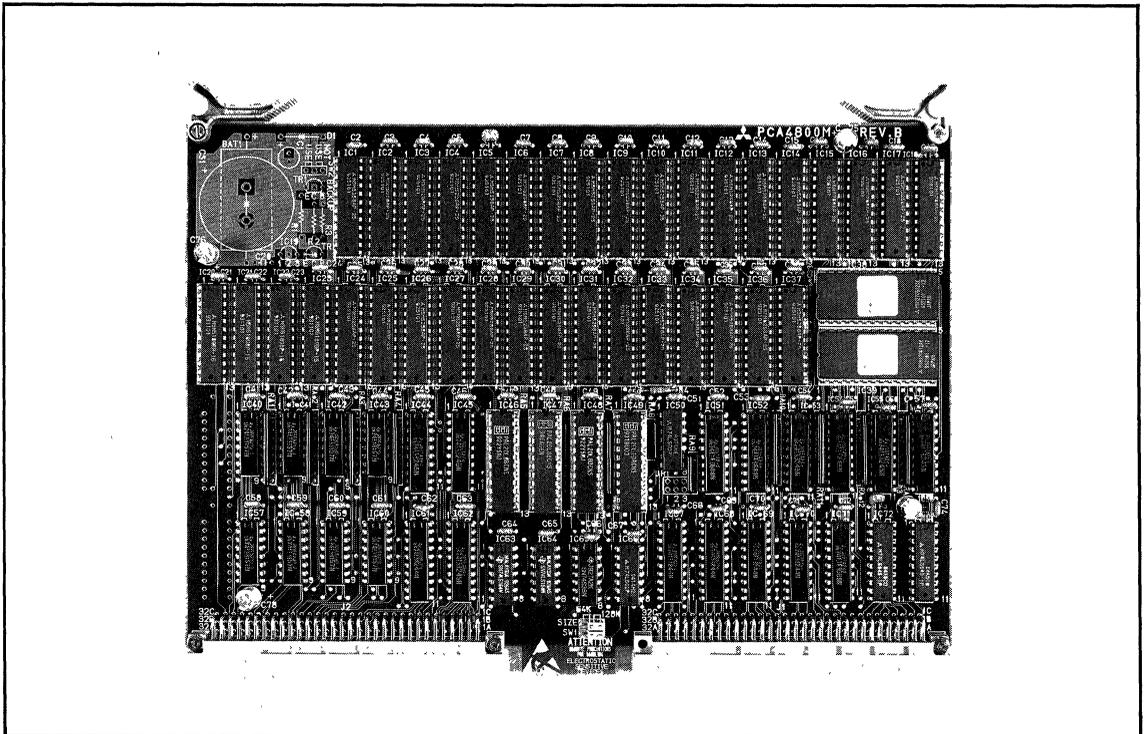

Fig. 1 The exterior of PCA4800M

M37700T-POD**MELPS 7700 EMULATION POD(SINGLE-CHIP MODE,CORRESPOND to PC4000E)****DESCRIPTION**

The M37700T-POD is an emulation pod constructs the option board for single-chip mode of MELPS 7700 emulation common board M37700T-RTT.

M37700T-POD is used with M37700T-RTT and PC4000E.

DISTINCTIVE FEATURES

- Debugging functions can be used to connect with PC4000E, M37700T-RTT, and this pod.
- It can be corresponded to a system with 16MHz oscillator.
- The M37700T-POD can be connected by an attached flat cable with the users system.
- The M37700T-POD can be use an internal clock or an external oscillator.

STRUCTURE

The M37700T-POD consists of the following hardwares :

1. Evaluation MCU (M37700SAFP) and related circuits.
2. Gatearray for port emulation and related circuit.

FUNCTIONS

To connect the M37700T-RTT, the M37700T-POD constructs the option board for single-chip mode of M37700M2-XXXFP or M37700M2AXXXFP.

The PC4000E debugging machine is controlled by the monitor program ROM on the M37700T-RTT, and the evaluation MCU (M37700SAFP) mounted on the M37700T-POD executes the program stored in the program RAM on the M37700T-RTT.

Single-step execution, execution with break points, and reading of internal status with the evaluation MCU halted are performed under the control of the monitor CPU on the PC4000E.

M37700T-HPD**MELPS 7700 HIGH LEVEL EMULATION POD(CORRESPOND to PC4816)****DESCRIPTION**

The M37700T-HPD is a high level pod for MELPS 7700 is an emulation pod which enables debugging system PC4816. It can be used as an emulator corresponding to M37700 and M37701 by connection with M37700T-CNT built-in PC4816.

DISTINCTIVE FEATURES

- The electrical characteristics of the direct ports is excellent because of the distance between the emulation MCU and the users system is short.
- The whole processor mode that single-chip mode, microprocessor mode and memory expansion mode can be corresponded alone.
- Compact pod

STRUCTURE

M37700T-HPD consists of the following hardware.

- (1) Evaluation MCU (M37700SAFP-A)
- (2) Clock oscillation compact board
- (3) Port emulation circuit
- (4) I/O buffer

SPECIFICATIONS

Item	Contents
Debugger	PC4816
Corresponding MCU	M37700, M37701
Clock frequency	16MHz
Corresponding control board	M37700T-CNT
Corresponding MCU mode	(1) Single-chip mode (2) Memory expansion mode of 8 and 16-bit bus width (3) Microprocessor mode of 8 and 16-bit bus width
Supply voltage	5 [V] \pm 5 [%]

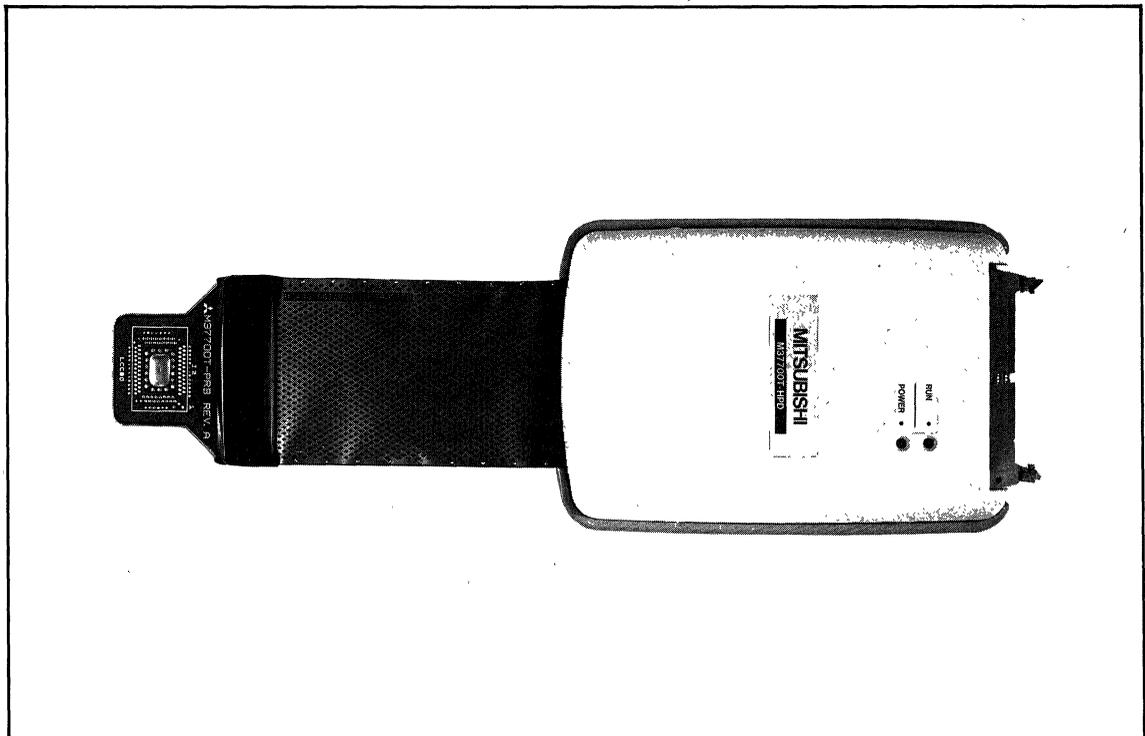

Fig. 1 The exterior of M37700T-HPD

M37704T-HPD

MELPS 7700 HIGH LEVEL EMULATION POD(CORRESPOND to PC4816)

DESCRIPTION

The M37704T-HPD is a high level pod for MELPS 7700 is an emulation pod which enables debugging system PC4816. It can be used as an emulator corresponding to M37704 and M37705 by conection with M37700T-CNT built-in PC4816.

DISTINCTIVE FEATURES

- The electrical characteristics of the direct ports is excellent because of the distance between the emulation MCU and the users system is short.
- The whole processor mode that single-chip mode, microprocessor mode and memory expansion mode can be corresponded alone.
- Compact pod

STRUCTURE

M37704T-HPD consists of the following hardware.

- (1) Evaluation MCU (M37705ASP)
- (2) Clock oscillation compact board
- (3) Port emulation circuit
- (4) I/O buffer

SPECIFICATIONS

Item	Contents
Debugger	PC4816

PRELIMINARY

MELPS 7700 HIGH LEVEL EMULATION POD(CORRESPOND to PC4816)

DESCRIPTION

The M37795T-HPD is a high level pod for MELPS 7700 is an emulation pod which enables debugging system PC4816. It can be used as an emulator corresponding to M37795SJ by conection with M37795T-CNT built-in PC4816.

DISTINCTIVE FEATURES

- The electrical characteristics of the direct ports is excellent because of the distance between the emulation MCU and the users system is short.
- Compact pod

STRUCTURE

M37795T-HPD consists of the following hardware.

- (1) Evaluation MCU (M37795SJ)
- (2) Clock oscillation compact board
- (3) Port emulation circuit
- (4) I/O buffer

SPECIFICATIONS

Item	Contents
Debugger	PC4816

PROGRAM WRITING ADAPTER for ONE TIME PROM VERSION MICROCOMPUTERS

DESCRIPTION

The PCA4707 is an adapter writing the program into the EPROM version microcomputer M37700E2-XXXXFP, M37700E2AXXXFP, M37700E4-XXXXFP, or M37700E4AXXXFP. It can be used the PROM writer (correspond to M5M27C2-56K) on the market to write the program through the PCA4707.

STRUCTURE

The PCA4707 is consisted of two printed circuit boards named PCA4707 and PCA4701B.

PCA4707 The EPROM version microcomputer is mounted on this board.

The PCA4707 has a 80-pin IC socket to mount the EPROM version microcomputer, and a dual in line socket to connect with the PCA4701B.

PCA4701B The PCA4701B has two dual in line connector. One of them is used connecting with the PROM writer, and another one is used connecting with the PCA4707.

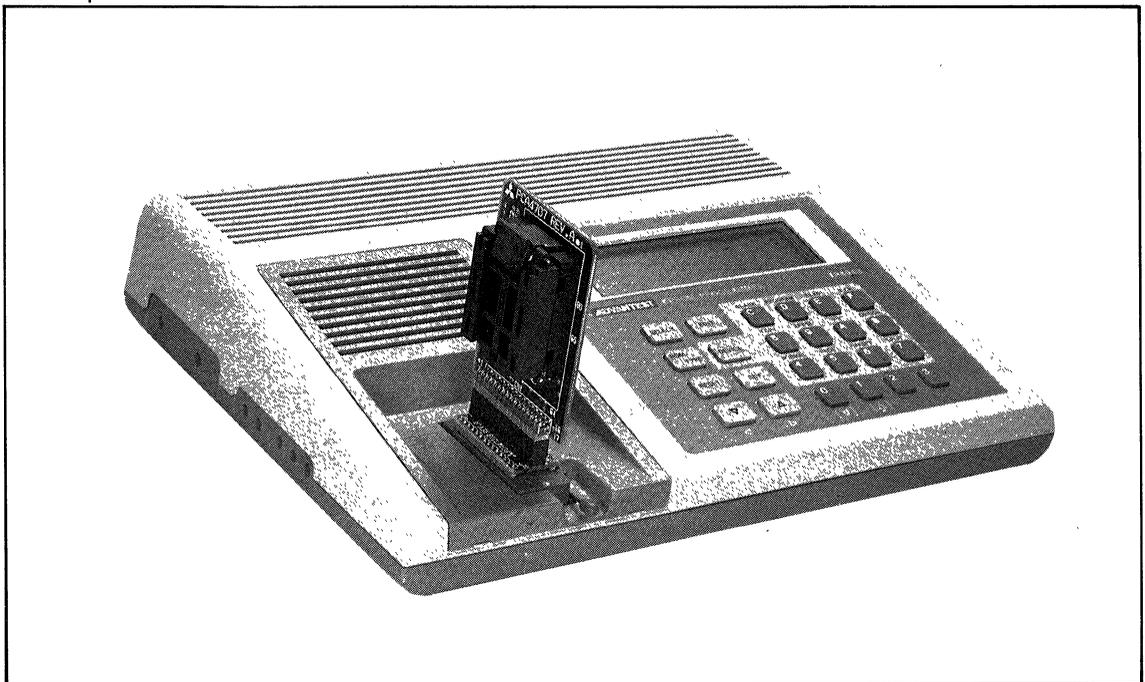

NOTE

Some kind of PROM writer cannot write the program on the EPROM version microcomputer through the PCA4707.

SPECIFICATIONS

Item	Specification
Correspond microcomputer	M37700E2-XXXXFP M37700E2AXXXFP M37700E4-XXXXFP M37700E4AXXXFP
Clock frequency	8MHz (ceramic oscillator on the PCA4707)
Power supply	Supplied from PROM writer
Specification of PROM writer	(1) Be able to write to M5M27C256K, or the other EPROM equal (2) Be able to write, to compare check, and erase check with designating the area (3) Be able to supply the current about 10mA from the source (5V line) to external.

An example to attach the PCA4707 on the PROM writer

PCA4709

PROGRAM WRITING ADAPTER for PROM VERSION MICROCOMPUTERS

DESCRIPTION

The PCA4709 is an adapter writing the program into the EPROM version microcomputer M37701E2-XXXSP, M37701E2AXXXSP, M37701E4-XXXSP, M37701E4AXXXSP, M37705E2-XXXSP, M37705E2AXXXSP, M37705E2SS, or M37705E2ASS.

It can be used the PROM writer (correspond to M5M27C2-56K) on the market to write the program through the PCA4709.

STRUCTURE

The PCA4709 is consisted of two printed circuit boards named PCA4709 and PCA4740B.

PCA4709 The EPROM version microcomputer is mounted on this board.

The PCA4709 has a 64-pin shrink DIP type IC socket to mount the EPROM version microcomputer, and a dual in line socket to connect with the PCA4740B.

PCA4740B The PCA4740B has two dual in line connector. One of them is used connecting with the PROM writer, and another one is used connecting with the PCA4709.

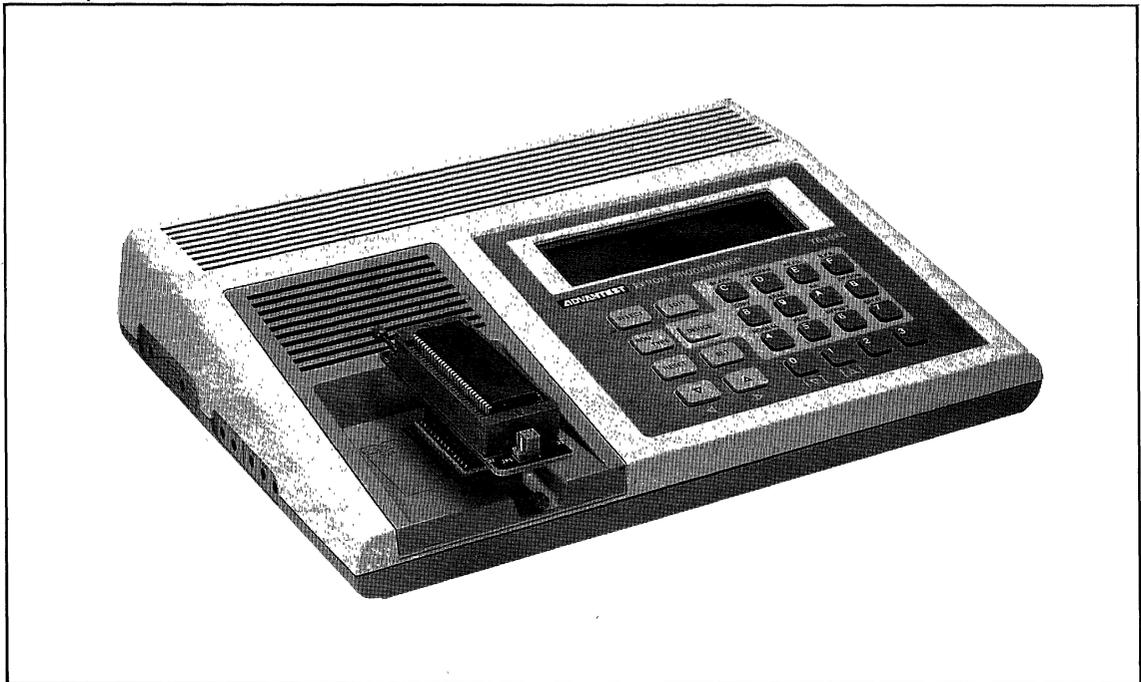

NOTE

Some kind of PROM writer cannot write the program on the EPROM version microcomputer through the PCA4709.

An example to attach the PCA4709 on the PROM writer

SPECIFICATIONS

Item	Specification
Correspond microcomputer	M37701E2-XXXSP, M37701E2AXXXSP M37701E4-XXXSP, M37701E4AXXXSP M37705E2-XXXSP, M37705E2AXXXSP M37705E2SS, M37705E2ASS
Clock frequency	8MHz (ceramic oscillator on the PCA4709)
Power supply	Supplied from PROM writer
Specification of PROM writer	(1) Be able to write to M5M27C256K, or the other EPROM equal (2) Be able to write, to compare check, and erase check with designating the area. (3) Be able to supply the current about 10mA from the source (5V line) to external.

PITCH CONVERTER for 80-PIN FLAT PACKAGE

DESCRIPTION

The PCA4780 is a pitch converter for 80-pin flat package connect the printed circuit pattern of the system mounted the 80-pin flat package single-chip microcomputer and that option board or evaluation board.

DISTINCTIVE FEATURES

- The PCA4780 can be used for an in circuit emulation probe to debug the system mounted the 80-pin flat package microcomputer.
- The PCA4780 can be converted the 40-pin, 1 inch dual in line pitch to 80-pin 0.8mm flat package pitch.

CONFIGURATION

The PCA4780 is structured following two parts

- (1) **FLAT80** : The printed circuit flexible board
 The FLAT80 has the 80-pin (0.8mm pitch) flat package pattern to attach the CUBE80 and two 40-pin connectors to connect the attachment cables of the option board or evaluation board, and these are connected one-to-one.
- (2) **CUBE80** : An electrode for flat package pattern
 The CUBE80 has two electrodes formed same as the 80-pin (0.8mm pitch) flat package microcomputer.
 One of that is connected with the user system, and another is connected with the FLAT80.
 It is necessary soldering to connect there.

ATTACHMENT

PCA4780 is attached the following process:

- (1) One of the electrodes of the CUBE80 is soldered with the user system, and the another is soldered with the FLAT80.
- (2) The FLAT80 is connected to the option board or the evaluation board by the attachment cables.
- (3) The GND electrode of the FLAT80 is connected with the GND electrode of the option board or the evaluation board.

SPECIFICATIONS

Item	Specification
Correspond package	80-pin flat package (pins interval 0.8mm) TYPE 80P6
Components	CUBE80 : Electrodes for the flat package FLAT80 : The pitch converter
Connection	CUBE80 : The FLAT80 and the user system by solder FLAT80 : Two 40-pin dual in line connectors and cables

New product

MITSUBISHI MICROCOMPUTERS PCA7780G02

PITCH CONVERTOR for 80-PIN FLAT PACKAGE

DESCRIPTION

PCA7780G02 is a pitch convertor for 80-pin flat package to connect the mounting pattern of the system mounted 80-pin flat package type single-chip microcomputer to the option boards, evaluation boards, and so on.

It can be connected to mounted evaluation microcomputer or the emulator by mounting the 80LCC IC socket to the foot pattern of 80-pin flat package on the target system.

DISTINCTIVE FEATURES

- It can be used as incircuit emulation probe to debug the system mounted 80-pin flat package type micro-computer.
- It can be converted the pattern that has 80-pin two line half pitch dual-in-line to the pattern of 80-pin flat package (0.8mm pitch).

The following boards and IC socket are needed to use PCA7780G02.

- (1) Using series MELPS 7700(M377XX)
PCA7781 : Pitch convertor
- (2) Using M37450 family
PCA7782 : Pitch convertor
- (3) 80LCC socket
 - Surface mounting type IC61-0804-034
(Yamaichi electric industry corporation.)
 - Manual solderable type 80LCC-046 (refer to figure 1)
(Mitsubishi electric corporation)

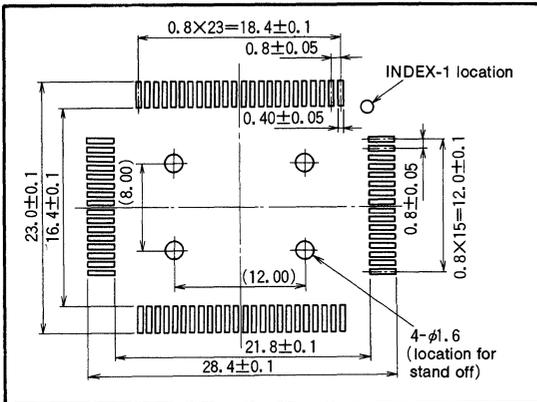

Fig. 1 80LCC-046 pattern

FUNCTIONS

The process of PCA7780G02 connecting as following.

- (1) Soldering the 80-pin LCC socket to the target system.
- (2) Connect the PCA7780G02 and PCA7781 or PCA7782 to the flat cable of the option board.
- (3) Connect the PCA7780G02 to the 80-pin LCC socket .
- (4) Connect the GND pin of PCA7781 or PCA7782 to the GND line of the option board.

SPECIFICATION

Item	Contents
Correspond MCU	80-pin flat package (0.8mm pitch) Type name is 80P6.

NOTE

The mounting pattern of 80QFP must be designed larger than normally to correspond to the packages 80P6, 80P6N, and two types 80LCC socket (refer Figure 2).

SERIES MELPS 7700 PROM ORDERING METHOD

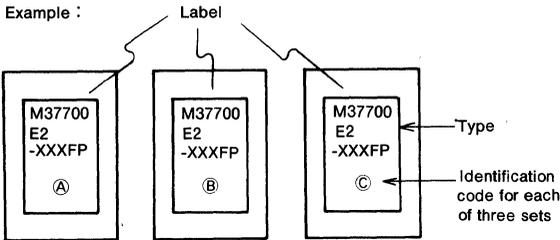

PROM ORDERING METHOD

Mitsubishi Electric corp. accepts order to transfer EPROM supplied program data into the one time PROMs in single-chip 16-bit microcomputers. When placing such order, please submit the information described below.

1. Writing to PROM Order Confirmation Form1 set
(There is a specific form to be used for each model.)
2. Data to be written into PROM built in..... EPROM
(Please provide three sets containing the identical data.)
3. Mark Specification Form1 set

NOTES

- (1) Acceptable EPROM type
Any EPROM made by Mitsubishi Electric corp. that is listed in the Writing to PROM Order Confirmation Form may be used.

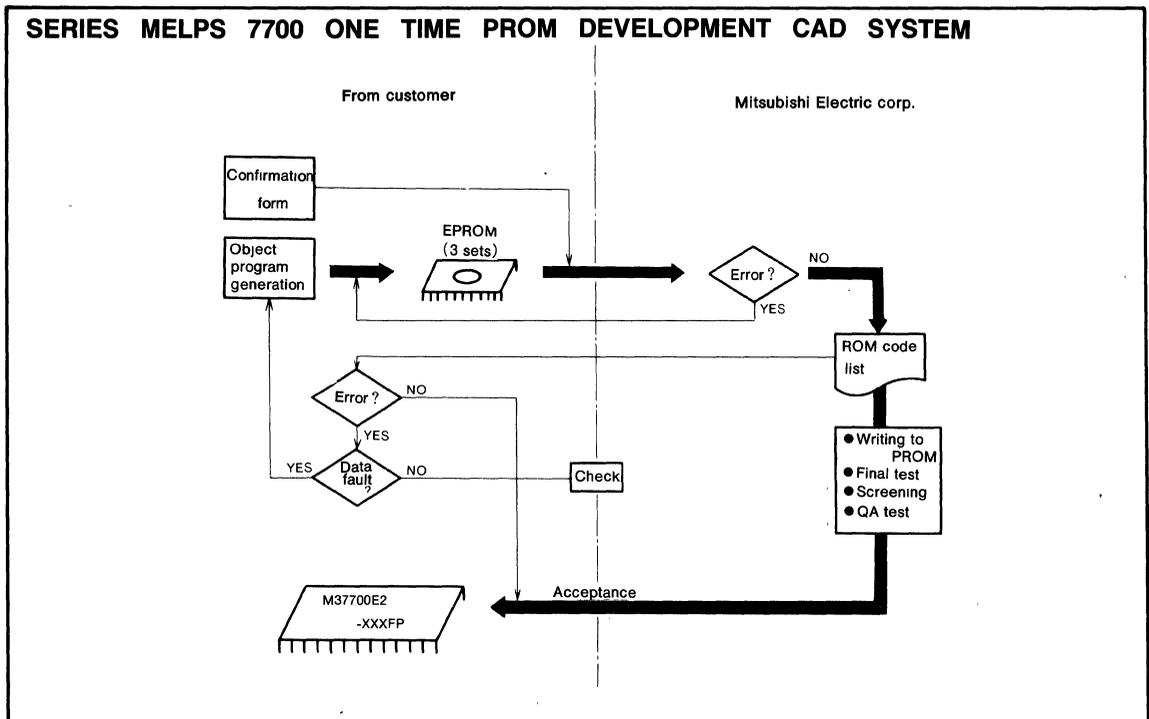

- (2) EPROM window labeling
Please write the model name and the identification code (A, B, C) on the label for each of the three sets of data EPROMs provided.
- (3) Calculation and indication of check sum code
Please calculate the total number of data in words in the EPROM, and write the number in 4-digit hexadecimal form in the check sum code field of the Writing to PROM Order Confirmation Form.
- (4) Marking specification method
The permissible marking specifications differ depending on the shape of package. Please fill out the Marking Specification Form and attach it to the Writing to PROM Order Confirmation Form.

OUTLINE OF ORDER PROCESSING

Mitsubishi Electric corp. will produce Writing to PROM if at least two of the three EPROM sets submitted contain identical data.

If we find error when the submitted EPROMs are compared, we will contact your representative. Thus, we assume responsibility only when we produce Writing to PROMs that contain data other than the data correctly provided by the customer.

The chart below shows the flow of one time PROM production.

Note : Please fill in all items marked※

※ Customer	Company name		TEL ()	Issuance signatures		
	Date issued	Date :				

※ 1. Confirmation

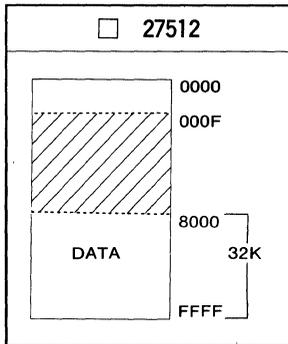

Specify the name of the product being ordered and the type of EPROMs submitted.
Three sets of EPROMs are required for each pattern (Check @ in the appropriate box).
If at least two of the three sets of EPROMs submitted contain the identical data, we will produce writing to PROM based on this data. We shall assume the responsibility for errors only if the written PROM data on the products we produce differ from this data. Thus, the customer must be especially careful in verifying the data contained in the EPROMs submitted.

Checksum code for entire EPROM areas

--	--	--	--

 (hexadecimal notation)

EPROM Type :

- (1) Set "FF₁₆" in the shaded area.
- (2) Address 0₁₆ to 0F₁₆ are the area for storing the data on model designation. This area must be written with the data shown below.
Address and data are written in hexadecimal notation.

	Address		Address
4D	0	41	8
33	1	FF	9
37	2	FF	A
37	3	FF	B
30	4	FF	C
30	5	FF	D
45	6	FF	E
34	7	FF	F

※ 2. Mark specification

Mark specification must be submitted using the correct form for the type of package being ordered fill out the appropriate Mark Specification Form (80P6 for M37700E4AXXFP) and attach to the Writing to PROM Order Confirmation Form.

MITSUBISHI MICROCOMPUTERS MARK SPECIFICATION FORM

64P4B (64-PIN SHRINK DIP) MARK SPECIFICATION FORM

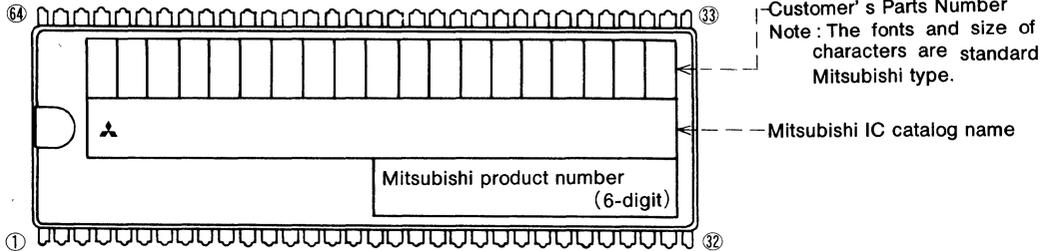

Mitsubishi IC catalog name

Please choose one of the marking types below (A, B, C), and enter the Mitsubishi IC catalog name and the special mark (if needed).

A. Standard Mitsubishi Mark

B. Customer's Parts Number + Mitsubishi IC Catalog Name

Note 1 : The mark field should be written right aligned.

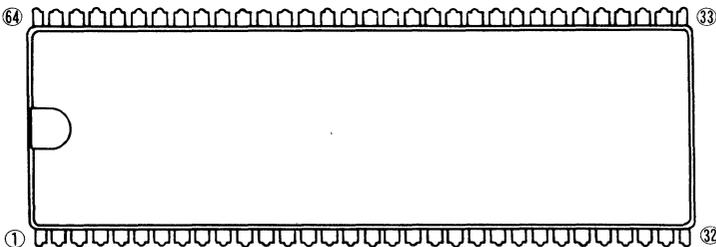

2 : The fonts and size of characters are standard Mitsubishi type.

3 : Customer's parts number can be up to 19 alphanumeric characters for capital letters, hyphens, commas, periods and so on.

4 : If the Mitsubishi logo is not required, check the box on the right.

Mitsubishi logo is not required

C. Special Mark Required

Note 1 : If special mark is to be printed, indicate the desired layout of the mark in the upper figure. The layout will be duplicated technically as close as possible. Mitsubishi product number (6-digit) and Mask ROM number (3-digit) are always marked for sorting the products.

2 : If special character fonts (e. g., customer's trade mark logo) must be used in special mark, check the box on the right.

For the new special character fonts a clean font original (ideally logo drawing) must be submitted.

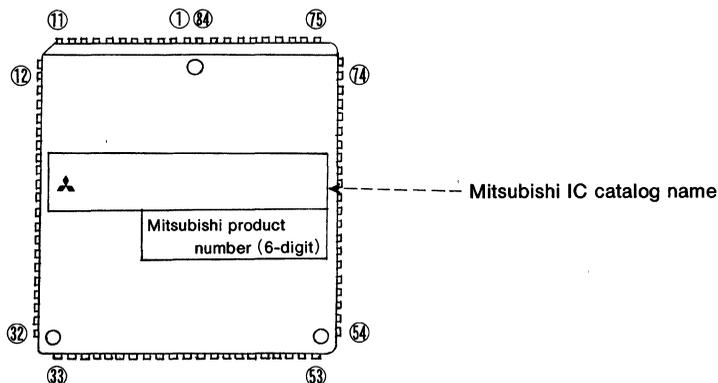

Special character fonts required

84P0 (84-PIN PLCC) MARK SPECIFICATION FORM

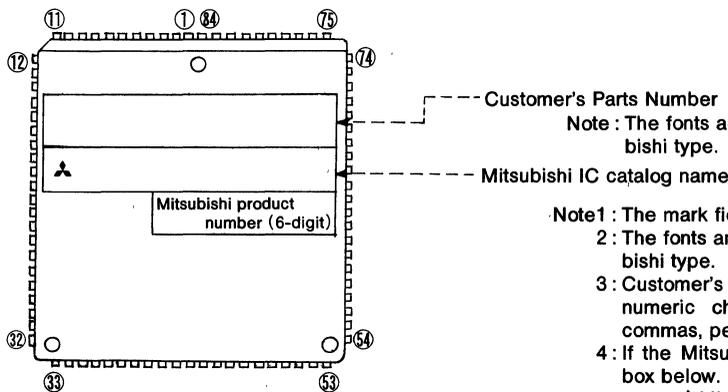

Mitsubishi IC catalog name

Please choose one of the marking types below (A, B, C), and enter the Mitsubishi IC catalog name and the special mark (if needed).

A. Standard Mitsubishi Mark

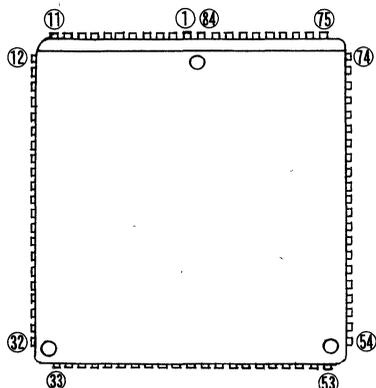

B. Customer's Parts Number + Mitsubishi IC Catalog Name

- Note 1:** The mark field should be written right aligned.
2: The fonts and size of characters are standard Mitsubishi type.
3: Customer's parts number can be up to 16 alphanumeric characters for capital letters, hyphens, commas, periods and so on.
4: If the Mitsubishi logo is not required, check the box below.

Mitsubishi logo is not required

C. Special Mark Required

- Note 1:** If Special Mark is to be printed, indicate the desired layout of the mark in the left figure. The layout will be duplicated technically as close as possible. Mitsubishi product number (6-digit) and Mask ROM number (3-digit) are always marked.
2: If special character fonts (e.g., customer's trade mark logo) must be used in special mark, check the box below.
 For the new special character fonts a clean font original (ideally logo drawing) must be submitted.

Special character fonts required
