## Foreword

COMPUTE!'s First Book of Commodore 64 Games is packed full of great games. But this book serves a double purpose.

First, it provides you with a variety of games, which you can merely type into the computer, save on disk or tape, and then play again and again.

Second, because the full program is here in print, you can see exactly how the game's creator brought off the effects you like.

In fact, to make this book as useful as possible, many of the games are accompanied by explanations of how the program works. Chapters at the beginning and end of the book will also help you learn how to write your own games.

In order to make typing in the programs as easy as possible, we have included three aids. Be sure to read over the article in Appendix A "Beginner's Guide to Typing in Programs." Also, review Appendix B "How to Type in Programs."

A number of the programs are written completely or partially in machine language. If you have ever typed in a machine language program with its hundreds of DATA statements, you will appreciate the "Machine Language Editor (MLX)" in Chapter 6. MLX is a BASIC program that will help you type in machine language programs perfectly the first time.
RP

# Why the Commodore 64 Is a Great Game Machine 

Eric Brandon

One of the first things a new programmer wants to do is write a game. The programmer soon discovers that there is no "move alien around" command; rather, the computer must be told what to do in hundreds of tiny little steps.

Fortunately, the Commodore 64 is loaded with features that make this arduous task much easier and reduce the number of steps that have to be programmed into the computer. The games in this book try to exploit these features as much as possible, to save the programmer time, and to save you typing.

## Parlez-vous BASIC?

What language to program the game in is the first decision the programmer must make. On the Commodore 64 the choice is between BASIC and machine language.

The native language of the computer is machine language. This means that programs written in BASIC have to be translated into machine language while they are running. That translation takes time, so BASIC programs run much slower than programs written in machine language.

Although machine language is much faster, it is also a more difficult language to use; so to speed up writing the game, many programmers opt for BASIC, or some combination of BASIC and machine language. The choice ultimately depends on how critical speed is to the game. Witness the incredible speed of "Munchmaze" or "The Viper," both written in machine language. Other
games where speed is not so important, such as "Mystery Spell," use no machine language at all.

The 64 makes machine language programming easier because it has a popular, easy-to-use microprocessor chip, and it has areas of memory where machine language programs can be conveniently tucked away.

## Make Your Own Alphabet

Whenever you see a letter or graphic character on the screen, you are looking at one member of a character set. The character set is where the computer goes to see what a character such as A looks like, before it can put it on the screen.

By holding down the SHIFT and Commodore keys, you can switch between two character sets. In one of them, character number one looks like this: A; in the other, it looks like this: a.

This is very important to the game programmer, because with the 64 he can create his own character set. For example, the programmer can tell the computer that character one is a happy face. From then on, moving a happy face around on the screen is just as easy as moving any other character. Here is a short program that changes the A character into a happy face:

5 REM DISABLE INTERRUPTS AND REVEAL CHARACTER ROM $1 \varnothing$ POKE 56334, PEEK (56334) AND254
$2 \emptyset$ POKE 1, PEEK (1)AND251
25 REM COPY CHARACTER SET DOWN TO RAM
29 PRINT "PLEASE WAIT $3 \varnothing$ SECONDS"
30 FOR I=ø TO $2 \varnothing 48$
40 POKE 12288+I, $\operatorname{PEEK}(53248+I)$
50 NEXT I
55 REM COVER UP CHARACTER ROM AND REENABLE INTERRU PTS
60 POKE 1, PEEK (1)OR4
70 POKE 56334, PEEK (56334)OR1
75 REM ENABLE NEW CHARACTER SET
8Ø POKE 53272,28
85 REM POKE IN HAPPY FACE OVER "A"
$9 \varnothing$ FOR I=Ø TO 7
$10 \emptyset$ READ A
110 POKE 12296+I,A
120 NEXT
130 END
195 REM EACH NUMBER IS ONE ROW OF THE DOTS THAT MA KE UP THE FACE
$2 ø \varnothing$ DATA $6 \emptyset, 66,165,129,165,153,66,60$

Even more powerful is the technique of telling the computer that character one looks like the left half of a spaceship, and character two like the right half. By combining redefined characters, you can create large shapes. This technique is used in "The Hawkmen of Dindrin."

## Another Way of Making a Spaceship

Sometimes a game needs objects on the screen that can go through or over other objects, like a spaceship moving over a starfield. Not only can the 64 do this, but also it will automatically detect a collision between objects.

These objects, called sprites, have a number of other useful features. Each of the 504 dots can be assigned a color independent of its neighbor, and the whole sprite can double in size either vertically or horizontally. Although only eight sprites can usually be displayed at a time, most games do not require that many.

Sprites can also be used for animation. The bird in Mystery Spell is a sprite. To make the bird's wings flap, several versions of the bird were drawn, with the wings up, midway, and down. By telling the bird to look like one shape after another, the illusion of flapping wings is achieved.

## Small Is Beautiful

Sometimes, instead of large objects, a game needs to work with pixels, the individual dots that make the image on your screen. High-resolution mode allows control over each individual dot on the screen.

With high-resolution graphics it is possible to make very detailed backgrounds on the screen, over which you can move the sprites that play the game. None of the games in this book use this technique because it would require the typing in of 8000 numbers that describe each of the dots on the high-resolution screen.

## Color Me 64

Every good game-playing computer has the ability to put color on the screen. Some have as many as 256 different shades of colors, and some have as few as six.

Just as important as how many colors a computer has is how many colors it can display at once. The 64 is very good at multicolor graphics. Any character or dot can be any one of 16 colors. Furthermore, each dot within a character or a sprite can have its own color.

## Breaking the Sound Barrier

One of the most important features of a good game is sound effects for explosions, fanfares, and other sundry noises.

The Commodore 64 incorporates a minisynthesizer called the SID chip. The SID chip can make three different tones at once, so that harmony and chords are possible. You can hear this in the short songs played by "Richthofen's Revenge."

Furthermore, the SID gives you control over attack, decay, sustain, and release, sophisticated sound characteristics that can make the same note sound like it came from anything from a drum to an underwater oboe.

## Join the Party

This book is more than a book of games. The Commodore 64 is a great machine with features that allow arcade-quality games. Some of these features take practice to learn.

Many of the articles include explanations of how the game was designed and how the features of the 64 were exploited. By typing in the games and reading the articles, not only will you have hours of fun playing the games, but you will also be learning many of the techniques needed to design your own games.

## 1

# Writing Your First Game 

## Richard Mansfield

Richard Mansfield, senior editor of COMPUTE! Publications, explains the details of a simple game. A beginning programmer can learn a great deal studying this short program.

If you are tempted to write your own games, go ahead. It's a good way to learn to program. Games are basically the same as any other kind of programming.

Computer games fall into two broad categories: 1. imitations of old standards (checkers, Othello) and 2. games which could not be played without a computer (Space Invaders, Pac-Man). This second category is more difficult to program for several reasons. For one thing, you've got to think up a whole new, and entertaining, concept and then adjust the action until it is just hard enough to be challenging but not so difficult that people want to give up.

This category (basically arcade games) is especially hard to program precisely because a good computer-only game exploits all of the computer's special attributes: speed, color, and sound. To do this well, to make things look and respond just the way you imagine them, requires a good bit of programming experience. Usually, too, several things are happening at once in an arcade game. This often means that such a program must be written in machine language, which is far faster than BASIC.

## High Card Slice

Old standards, on the other hand, can often be the best way to get started programming games. You already know the game concept, and cards or dice or game boards are fairly easily constructed and manipulated on your computer screen. To illustrate, let's take a look at a simple simulation of one of the oldest card games, "High Card." The rules are simple: you place a bet,
and then you draw a card from the deck. The computer, your opponent, draws a card too, and the highest card wins the money.

One simplification here is that there is no attempt to represent the cards on the screen. The entire game relies simply on words (Ace of Spades, for example) when cards are drawn.

Like most computer programs, the program can be visualized as having four distinct zones: initialization, main loop, subroutines, and data tables. We can go through the steps in programming this game by looking at each zone separately.

## Initialization

From lines 10 through 80 we are teaching the computer some basics about this game. Initialization is the activity which must take place before any of the action can begin. Computers are so fast that they will zip up through these lines and start things off in the main loop at line 100 in a flash. However, as programmers, we are aware that several preliminary events took place inside before anything else.

In line 20, the computer discovers that there is a variable called DOLLARS which is set equal to 500 . It sets aside a section (like a small box) in its memory which it labels DOLLARS. When the game is running, it will add or subtract from this box (lines 230-240) to keep a running total of how much money you have left to bet. From time to time (line 110), it will check the box and report to the player how much he has. The box labeled DOLLARS is called a variable because during the game the amount in it will vary.

Lines 30 through 60 are simple enough-they ask the player to give his or her name. The computer memorizes it in another box called NAME $\$$ and can now speak more personally to the player in lines 140 and 230. Also, the computer prints the rules of the game in line 60.

Line 70 READs four names (the face cards) from the data tables in lines 510 on. It also makes a mental note that it already READ four items. So, when it's asked to READ again (line 80), it will start with the next unread item of data which will be CLUBS. By now, the computer has memorized a variety of important facts: the player's name, the amount of his or her betting purse, the names of the face cards, and the suits of a standard deck. In less than a second, the computer has grasped and filed away the necessary facts to go on to the main loop where all the action takes place.

## The Main Loop

After checking that the player has money to bet, the computer asks for the bet, checks again that the bet is possible, and then runs through one cycle of the game starting in line 160. At this point, a programmer might find it worthwhile to visualize the steps involved in the game: draw a card for the player; draw for the computer; decide who won; adjust the player's purse.

Since both draws are essentially identical actions (the only difference will be that we say "Bob draws a . . ." instead of "The computer draws"), we don't need to program the draw twice. This is where subroutines come in handy.

## The Subroutine

Twice in the main loop, we GOSUB 300. First the player, then the computer, draws. Line 310 randomly picks two numbers, the card and the suit. If line 320 finds that this selection matches the one drawn just before by the player, it goes back for another draw. Line 330 makes the name of the card be the number if it is less than 11 (a face card).

Then line 340 announces the draw using three variables. The first variable (PLAYER\$) is set up in either line 160 or 190 as appropriate. Then the CARD\$ and SUIT\$ variables are selected from the lists that were memorized back in the initialization phase (lines 70-80). The subroutine then RETURNs to the main loop.

Lines 210-240 decide and announce the winner of this round. First, if the variable CARD (the computer's card) is greater than ( $>$ ) YOURCARD, the computer is declared the winner in line 240, the purse is adjusted, and the main loop is restarted (GOTO 100). If the cards are equal, nothing happens to the purse and the next round begins. Notice that we don't need to say IF YOURCARD > CARD at the start of line 230 to test if the player has won. It's the only possible thing if the computer has gotten this far.

Once you've solved a particular problem, you'll find you can use the solution in many future games. This subroutine which draws cards, for instance, would work just as well for Poker, or Blackjack, or dozens of other games. Subroutines are handy not only because they can be used repeatedly within a program, but because they can also be saved and used repeatedly in future programs. So think up a simple, traditional game and teach it to your computer. There is probably no more pleasurable way to learn programming than to write a game.

## High Card

# Writing a Simulation Game 

## Richard Mansfield

#### Abstract

A simulation is an imitation of life. It can be the most difficult type of game to create. Thought, rather than fast action, is important. Try the short simulation offered here, then see if you can write one of your own.

There are three basic types of computer games: arcade, adventure, and simulation games. Let's briefly look at the characteristics of arcade and adventure games and then write a simulation.

## Realtime Action

Arcade games feature what's called realtime action. Unlike chess or bridge, things happen fast. You can't sit back and plan your next move; you must react immediately to the space invaders. In other words, events take place at the same speed as they would in reality: realtime.

Arcade games also have a strong appeal to the eye and ear. There is much animation, color, and sound. In fact, your ability to respond quickly and effectively depends in part on all the clues you get from the graphics and sound effects. Strategy, while often an aspect of arcade play, is clearly secondary. These games are a new kind of athletics: the fun of man versus machine. Like auto racing, arcade games are essentially isometric exercises-you don't run around; you just stay in one place flexing and unflexing your muscles, tensing and relaxing.

## Story and Strategy

Strategy, however, is more important in "adventure" games. The emphasis is on planning ahead and solving riddles. It can be like living inside an adventure novel. There is drama, characterization, and plot. You might start out, for example, in a forest with a shovel and a trusty, if enigmatic, companion parrot. As you try to figure out what to do next, the parrot keeps saying "piny dells, piny dells." After wandering aimlessly through the trees, it
suddenly comes to you that the bird is saying "pine needles" and you dig through them and find a treasure map.

Your "character" will travel, meet friends and enemies, and have the opportunity to pick up or ignore potentially useful items such as food, magic wands, and medicine. It's customary that you cannot haul tons of provisions. You'd have to decide whether or not to leave the shovel in the forest. Yet you might be sorry that you'd dropped it if you're involved in a cave-in later in the game.

In any case, adventure games are fundamentally verbal. The computer displays the words:

YOU ARE IN A BOAT ON A LAKE. NIGHT IS FALLING.
to which you can respond in any number of ways. You might type:

DIVE OFF BOAT.
and the computer would reply that you now see an underwater cave or whatever. You move through the scenes the way a character moves through a novel. There is generally no penalty if you take time to plan your next move. It's not realtime.

## Imitations of Life

The third category, simulation, is the least common kind of computer game. This is because to really imitate something, to simulate it effectively, you need lots of computer memory to hold lots of variables. However, memory has recently become far less expensive so we can expect to see increasingly effective simulation games. Star Trek and Hammurabi, both simulations, have long been popular home computer games. Although they are similar to adventure games, simulations are random. That is, there is no secret to discover, no puzzle to solve, no plot. Like real life, things
gold can change by $\$ 20$ an ounce ( Y ). Variable Z will be used to simulate flipping a coin. Also notice lines 520 and 525. In 520, we determine whether or not there will be unrest. The variable CH is just a counter. Each "month," CH is raised by one. Two conditions are required for unrest to happen: in a given month, CH must be greater than 4 and it must be less than whatever $X$ turns out to be. If both these conditions are met, CH is reset to zero and we've got international unrest. This has the effect of creating unrest roughly every four to six months. Likewise, another rhythm is set up in line 525 to cause market rallies. In both cases, however, you cannot be certain exactly when to invest in gold or in stocks.

The decision to raise or lower stock prices is made in line 530 and based on the coin toss variable, Z. Again, stocks move in opposition to gold. Prices will rise about 50 percent of the time, but you can never know what will happen in a given month.

## Suggested Complications

This is the core, a rough sketch, of an investment simulation game. There is much you can do to make it a more effective simulation and thereby a more enjoyable game. The more variables in a simulation, the better. For example, add leverage and additional "incidents" which affect prices, improve the randomizing, and include other types of investments. You could even use a separate counter which, every five years, causes the $X$ and $Y$ variables to swing more widely to reflect recession/recovery cycles.

As you can see, a simulation should be lifelike. It has interdependent cycles and a degree of unpredictability. Its realism derives from including a sufficient number of variables. And those variables must interact in plausible ways and with just the right amount of randomness. A simulation is a little world you create. You can define cause and effect and then fine-tune the whole thing until it seems well-balanced. Adventure and arcade games are certainly enjoyable, but this investment simulation can be built up to the point where it's just as much fun as any other kind of game.

## Mixing Styles

Of course, these three categories-arcade, adventure, and simu-lation-are somewhat arbitrary. Some of the best games contain elements of each. There are adventure games with graphics-you see the forest, the shovel, the pine needles. After you say DIVE, your character jumps into a lake and the screen transforms into an
underwater scene. Likewise, arcade games can include the different "settings" so characteristic of adventure games. Popular arcade games such as Tron and Donkey Kong change the playfield as you earn more points.

There are several ways to add to the appeal of our investment simulation, beyond just making it a more complex, more accurate simulation. You could add the visuals and sound of arcade games. Try creating a ticker tape across the top of the screen to show price changes and news events. Maybe add a bell sound to indicate the end of further transactions. And from adventure games you could borrow two elements: riddles and the necessity of planning ahead. One easy way to incorporate these two elements would be to make paying taxes a part of the game. After all, the closer it is to real life, the better the simulation.

# Writing an Arcade Game 

Richard Mansfield

Using the memory-mapped video could help you create faster moving games. The sample program here will assist you in designing your own fast-moving game.

When you bring home your computer, usually the first thing everyone expects you to do is to write an arcade game. Who's "everyone"? It could be your children, your friends, even youanybody who is tired of spending lots of money and wants you to program a game to play at home for free.

The best defense is to politely point out that:

1. Arcade games are among the hardest types of software to write.
2. Professionals, working in teams, can take a year to write one.
However, it is well worth trying to write action games. You might not be able to duplicate the speed or complexity of professional games, but you can create very entertaining games of your own. After you've spent a few weeks getting familiar with BASIC and have typed in a few games, you are ready to take up the challenge. This is one of the best ways to learn some important programming techniques and to explore the graphics and sound capabilities of your computer.

## Ten Million IF/THENs

Your main problem is going to be speed. BASIC, though fast enough for most jobs, is pretty slow when it has to keep track of ten aliens, two mother ships, torpedoes, stars, and the player's position. All these things are in motion at once. You need to have a way to control players, to detect collisions, to score points, etc. We at COMPUTE! received a letter from reader John Anderson which touches on these problems:

In order to make a fast, effective "arcade-style" game, I would like to know how to let my computer know where a large number of things are on the screen (like walls in a maze) without $10,000,000$ IF/THEN statements. I would also like to know how to keep things, like the little figures racing around during a game, from plowing through walls and wiping them out or coming back onto the other side of the screen.
As Anderson points out, the first solution that comes to mind is to use an IF/THEN test for every possible event in the game. IF the ball hits the target, THEN raise the score. IF the ball misses the target, THEN let it move one more space. And on and on. This quickly slows the action down to a crawl.

## POKE Ping-Pong

One of the simpler arcade games is a simulation of Ping-Pong. You need to keep track of only three things: two paddles and one ball. Let's start off by solving the hardest problem. How can we bounce a ball around the screen both quickly and accurately?

The key to the problem is the fact that many computers have an area set aside in RAM which is an image of what you see on screen. This is called memory-mapped video and most computers have it. It means that if you POKE into that area of RAM, a character will appear on the screen. The next RAM byte address is the next space on screen, and so on. You can use this built-in "map" to tell what is where by using the fast PEEK command, and you can move things quickly with POKEs.

The example program will work on all VICs.
SCR = The address where screen RAM memory starts.
$\mathbf{L N}=$ The length of one screen line.
WALL = A solid square that appears when this number is POKEd anywhere into SCR.
BLANK = A blank space character that returns the screen to normal if POKEd into SCR on top of a WALL or FIGURE.
FIGURE = A character that, when POKEd into SCR, looks like a ball.
The memory cells holding the screen image are located in different places. The VIC determines where it starts by using the formula in line 100. First, draw a border around your screen like a picture frame. Perhaps print reversed spaces all around. (See lines 250-310.) This border is very useful. It will let you know when your ball has hit the edge.

LOC is a variable in the program that's always changing whenever the ball changes. It keeps track of the current location of the ball. What you do is keep another variable (VECTR, in this example) which holds the direction and distance of the ball's current motion. When VECTR is added to LOC, we know where to move the ball next.

There are four possible directions to go in the simplest kind of animated games. Traveling up, VECTR = -LN since you subtract the number of spaces in one screen line to move the ball to the line above. Going down is +LN , right is +1 , left is -1 .

Notice line 180. That is how the computer tells if the ball has reached a border. The next position the figure is supposed to be POKEd into is checked to see if the WALL variable is sitting there. If not, the figure is moved (lines 200-220). If there is a wall, line 190 reverses the figure's direction.

If you type in the example program, you'll be on your way to making a Ping-Pong game that will be as fast as you could want. What's left is to play around with VECTR to get different angles of bounce off walls so the ball can go anywhere. Then add two movable pieces of wall (paddles) and scorekeeping.

# Adding Joysticks to Your Games 

## Siliconomics

Joysticks would be easier to use if each direction had its own separate memory location. That way, you could check the north, south, east, west, and joybutton bits separately. But to economize (and you always do when designing microchips, where the cost is more than proportional to the amount of silicon used), all the bits are grouped together into a single memory byte (eight bits = one byte). The bits are ordered like this:

| Direction | Value When Off (Zero When On) |
| :---: | :---: |
| North: | 1 |
| South: | 2 |
| West: | 4 |
| East: | 8 |
| Button: | 16 |

As we'll explain shortly, your program will detect which way the joystick is deflected by looking at this byte. The number in the byte will be the sum of all these values. Here's how it works.

Let's ignore the joybutton for a moment. If the stick is not moved, the summed value in the byte would be 15 $(1+2+4+8=15)$. If the stick were moved up (north), the north value would becomezero, and the remaining numbers would add up to 14. If the joystick were moved left (west), the west value would become zero, and the remaining numbers would add up to 11.

The easiest way to use the joystick is to read the memory location with the BASIC command PEEK and use IF/THEN statements to take appropriate actions for each direction. Refer to this diagram:

A series of IF/THEN statements might look like this:

```
1\varnothing V=PEEK(56321)AND15
20 IF V=14 THEN PRINT "NORTH"
30 IF V=13 THEN PRINT "SOUTH"
4\emptyset IF V=7 THEN PRINT "EAST"
5\emptyset IF V=11 THEN PRINT "WEST"
60 IF V=6 THEN PRINT "NORTHEAST"
7\emptyset IF V=5 THEN PRINT "SOUTHEAST"
8\emptyset IF V=9 THEN PRINT "SOUTHWEST"
9\varnothing IF V=1\varnothing THEN PRINT "NORTHWEST"
1ø\emptyset IF V=15 THEN PRINT "CENTER"
11\varnothing GOTO lø
```

Line 10 reads the value of the joystick byte and keeps it in a variable, V . The number 56321 is the memory location for joystick port \#1. PEEK reads this location, but you won't get just values from 0-15. Other functions are also read here, such as the joybutton. The AND15 isolates the values we're looking for by turning off all the other unwanted bits. I won't explain here why this works-just take my word for it.

## Who's on First?

You can read the second joystick (port \#2) by substituting the number 56320 for 56321 in line 10. It might seem logical that the joystick which is read by PEEKing location 56320 should be the first joystick, since it has the lower number, but that's not the way it works. You can't argue with the lettering on the side of your Commodore 64 which clearly shows which is first and which is second.

Also, you'll notice that the first joystick will seem to press

## Another Way

Although the sample program above will read the joystick, it's not necessarily the best way. IF/THEN statements are among the slowest statements in BASIC, so if speed is important (as in certain keys on your keyboard. This is a hardware anomaly, but you can play some joystick games by pressing keys in the upperleft part of your keyboard. It is not a reliable method, however. games), there are better ways to go. Here's a faster method. Change line 10 to:

Now the values returned will be:

Notice that the range is smaller here. You can now use the values as the index to an array. Watch how it works. Let's shorten the example program:
$1 \varnothing$ FOR I=ø TO 1 $\varnothing$ :READ AS:MESSAGE\$ (I)=AS:NEXT I
$2 \emptyset$ DATA CENTER,NORTH, SOUTH, ,WEST, NORTHWEST, SOUTHWE ST, , EAST, NORTHEAST, SOUTHEAST
$30 \mathrm{~V}=15-$ ( $\operatorname{PEEK}(56321)$ AND15)
$4 \varnothing$ PRINT MESSAGE\$(V):GOTO 3Ø
MESSAGE (pronounced message-string) is a string array. A string array is a single variable name that holds a whole list of strings (a string is any series of characters). Each string has its own box or place in the array. We address the item in the list by calling its number. The READ loop on line 10 fills the MESSAGE\$ array with the ten strings. If we say PRINT MESSAGE\$(0) we'll get CENTER. PRINT MESSAGE\$(5) gives NORTHWEST.

Some of the DATA items are followed by two commas, which are separators. The computer interprets this to mean that between the commas there is a null (empty) string. It saves us from having to include items we don't need (since some of the numbers in the range 0-10 don't correspond to any joystick direction).

## Table Look-Up for Speed

Printing the messages indirectly by using the joystick number is a form of table look-up. Instead of having the computer go through a bunch of IF/THENs, or searching a list for an answer, table lookup is direct and fast. All the answers are already determined. This is especially useful for games, where speed is important. For
example, you could use a different character for any direction the player is facing, and put them into an array to be selected by the joystick number.

## Tricky Techniques

You can also read the joystick by masking (isolating) the bits you are looking for. Remember that each direction has a number associated with it. If we want to check for north, we just check to see if the north bit has turned to zero. If we're checking for north this way, we'll capture northeast and northwest as well, which we wouldn't have caught with a mere IF/THEN statement.

Here we'll mask out the north bit:
$\mathrm{V}=(15-\operatorname{PEEK}(56321)$ AND15) AND 1
If $\mathrm{V}=0$, the joystick is not deflected north. If $\mathrm{V}=1$, the joystick is being moved north, northeast, or northwest.

To check for left (west):
$\mathrm{V}=(15-\mathrm{PEEK}(56321)$ AND15) AND 4
If $\mathrm{V}=0$, there is no movement to the left. If $\mathrm{V}=4$ (yes, 4 , not 1), the stick is being pressed left, northwest, or southwest. See how you can separate the original four directions from the eight possible ones?

So, to check for any direction, use:
$\mathrm{V}=\mathrm{PEEK}(15-\mathrm{PEEK}(56321)$ AND15) AND number
V (or whatever variable you use) will be either zero (not deflected) or nonzero (deflected). Substitute $1,2,4$, or 8 for number ( $1=$ up, $2=$ down, $4=$ left, $8=$ right $)$.

## The Joybutton

You can check for the joybutton, also called the fire button or trigger, with:

Bl $=\operatorname{PEEK}(56321)$ AND16
B2 $=\operatorname{PEEK}(56320)$ for port \#1) $)$
A zero value means the button is pushed. A nonzero value (16) means the button is not pushed. For example, if you are waiting for the user to press the button to begin a game, you could use a loop:

## It's a Natural

Using a joystick in your next game will make it easier to play, since joysticks seem more natural than pressing keys on the keyboard. But remember that a joystick is just a tool. It will not move objects around for you - it will just tell you how the user is deflecting the joystick.

There are other uses for joysticks besides games. Unlike the keyboard, with its 50 -odd keys to deal with, the joystick limits input to just nine possibilities (the eight directions and the joybutton). The joystick can be used to select menu options, answer simple questions (left = no, right = yes), and even enter text (as you do with arcade games when you set the high score). Study the following example program for more ideas.

## Program Explanation

This program contains three subroutines you can use in your own programs. Lines $10-70$ just test the subroutines and show you how to use them. The subroutine at 500 will accept a yes or no answer (left = no, right = yes) and return it in A\$.

Lines 700-770 let the user enter a number by counting it up and down with the joystick. The number can be found in the variable C. C will not exceed the limits of MN (minimum) and MX (maximum). The user presses the joybutton to exit. Notice the POKE 198,0. Since the first joystick interferes with the keyboard, this POKE is used to clear it out.

You can use the subroutine at 800 to accept a letter of the alphabet. The letter is returned as a number from 1-26 in the variable C. In the sample program (line 20), it is used to accept a three-digit string of initials.

## 2

## Rats!

 Mike Steed 64 Translation by Gregg PeeleThis impressive game makes you feel that you are inside a maze, not just seeing it from above. Three-dimensional views appear as hallways, doors, and corners as you struggle to find the way out.

You must find your way through a maze displayed from a rat's eye view. After you have solved the maze, the program displays the top view and traces your steps.

First, you are asked what maze size you want, up to 15 by 15 (you may wish to change the DIM statement in line 49-add two to the largest dimension you want - and line 43). Line 45 checks to see if the machine code has been POKEd in, so you have to wait for that only the first time.

The space bar is used to move forward, and the J and L keys are used to turn left and right, respectively (turning doesn't change your location; it just gives you the view in another direction). The M key will display the top view of the maze, mark your position, and tell you in which direction you are headed.

There are five machine language routines in "Rats!" LINE, as its name implies, draws a line; this routine is similar to Applesoft's HPLOT TO or Atari BASIC's DRAWTO command. PLOT sets the hi-res cursor to the position from which the next line is to be drawn, and plots that point on the screen. The COLOR routine fills the screen with color.

INIT removes everything that is not a letter or number from the screen (thus the quarter-square graphics are erased, but not the MOVE XX at the bottom of the screen), and sets all the variables used by the other routines (locations 826-837) to zero.

SCR either loads or saves something to or from the screen. This routine is used to save the screen to memory after the top view of the maze has been displayed the first time, and from then on is used to display the maze almost instantly, so you have to wait only once.

## Typing in the Programs

Whenever you run Rats!, you must prepare the computer by first running Program 1. Tape users should not enter line 180; likewise, disk users should not enter line 190.

Program 1 will automatically LOAD and RUN Program 2. Therefore, it is necessary for tape users to SAVE Program 2 immediately following Program 1, and disk users should SAVE
Program 2 on the same disk as Program 1, using the filename Rats.

## Program 1. Rats! Part 1

In "Goblin," custom characters are used to create a simple yet entertaining game. The object is to capture the scowling creatures with your goblin while avoiding the many block-shaped obstacles that lie in your path.

After obstacles and sad faces have been positioned, "Goblin" begins when the main character appears at the bottom of the screen. As the game progresses, the goblin moves continually upward and the player controls only its horizontal movement. The $O$ and $P$ keys, in conjunction with the GET command in line 260, enable the player to move the goblin left and right, respectively. Children especially like the cumulative effect of the GET statement; they make rapid key punches and then wait for the delayed effects.

As each sad face is captured by the goblin, the score is updated and printed at the upper left. If the goblin successfully clears the screen of all the faces, an entirely new playfield will be provided. A game lasts as long as you wish.

A single round ends when the goblin crashes into an obstacle. At this point, the remaining sad faces smile, and you are asked if you wish to play again.

If you play again, your previous highest score will be posted as the new game begins. The incentive to exceed a record score makes any game more fun.

# Snake Escape 

Daryl Biberdorf 64 Translation by Patrick Parrish

You'll have to watch out for poisonous mushrooms as you race against the clock towards your goal in "Snake Escape."

In "Snake Escape", your goal is to move a snake out of a poisonous garden. There are approximately 150 poisonous plants on the screen after you enter your skill level. The snake appears in the upper-left corner after all poisonous plants have been placed. You then attempt to get the snake to the escape hole within the time limit you chose earlier.

The snake must reach the hole without hitting a poisonous plant, running into itself, or running out of time. If it reaches the escape hole safely, you will receive a bonus in addition to your score. The snake grows as it moves along; you receive one point for each body segment it adds while moving. If it runs into itself or a poisonous plant, a cross will appear in the center of the screen with your score and the number of remaining snakes. You may stop the snake if you wish by simply releasing all keys, but remember this costs you time.

## Strategy

If you are running your snake near the left or right edges of the screen, remember that the 64 has horizontal screen wraparound. You may end up hitting a poisonous plant on the other side of the screen, so be careful! Occasionally, the snake will be cornered between plants and itself due to a miscalculation in maneuvering. Try to fill up all the spaces you can in the cornered-off area. You may lose a snake, but you will still receive a few extra points. Also, try to keep moving at all times. And watch where you're going.

The direction in which the snake moves is determined in lines 200 through 230. As written, keys I (up), J (left), K (right), and $M$ (down) move the snake. If you aren't comfortable controlling the snake with these keys, you can easily change the program to accept other key commands.

For instance, suppose you want to use the $Z$ key rather than the J key to move the snake left. Since location 197 reads the keyboard, you must first determine the number which is POKEd into this location when Z is pressed. Type the following line:
1 PRINT PEEK(197):FOR I=1 TO 4øø:NEXT I:GOTO 1 and then RUN the program. Next press the Z key, and the number in location 197 corresponding to the Z key (12) will print repeatedly on the screen. Try some other keys, noting their values, then hit the RUN/STOP key.

You are now ready to make the modification in line 200: substitute 12 for 34 . RUN the program (after deleting line 1, of course); you can move the snake left with the Z key.

\title{
States \& Capitals Tutor
}

\author{
Enoch L. Moser
}

\begin{abstract}
"States \& Capitals Tutor," in addition to being a useful tool for students who are learning the American states and capitals, also demonstrates the use of arrays in programs and the storage and retrieval of data on cassette. Both of these concepts are important to programmers, but nonprogrammers may use States \(\mathcal{E}\) Capitals Tutor without delving into the working details.
\end{abstract}
"States \& Capitals Titor" asks a student the name of either a state or a capital, and keeps track of correct and incorrect responses. The program randomly decides whether to quiz the student on either states or capitals and also chooses the questions randomly.

Questions answered correctly are not repeated. However, the program will repeat questions that are missed. And like any good teacher, States \& Capitals Tutor will help students who ask for it. Students who are stumped can simply type HELP. The program gives the correct answer and comes back to the troublesome question later. It also keeps track of how many times the student asks for help.

When all 50 states have been correctly matched with their capitals, and if the student has not asked for help or missed any questions, he or she is rewarded with a perfect score message.

\section*{A Two-Part Program}

The program reads the states and capitals from a disk or tape file which is generated by Program 2, "File Maker."

To use these programs, follow this procedure:
1. Type in Program 1. Line 5 for tape users should be 5 OPEN 1,1,0, "STATES"
Line 5 for disk users should be 5 OPEN 1,8,0, "STATES"
2. SAVE Program 1 to disk or tape. Tape users should leave the tape at its position after the SAVE.
3. Type in Program 2 (File Maker). Line 40 for tape users should be
\[
40 \text { OPEN 1,1,1, "STATES" }
\]

Line 40 for disk users should be
40 OPEN 1,8,1, "STATES"
4. RUN the program. The states and capitals will be on the tape or disk under the filename STATES. (Tape users should leave the tape in its position.)
5. SAVE Program 2.
6. Rewind the tape.
7. LOAD Program 1; leave the PLAY button pressed and the tape in position when loading is complete.
8. RUN Program 1.

\section*{How the Programs Work}

As mentioned, the File Maker program stores the states and capitals on tape or disk under the filename STATES. The main program, States \& Capitals Tutor, reads this file and stores the data in ST\$ (I,J), a two-dimensional array (more on this in a moment). When a right answer is given, the range of the random number generator (line 100) is decreased by one (line 205), and that state/capital is moved to the top part of the list (lines 180-200), out of the range of selection. Otherwise, the program is fairly straightforward.

The definitions of the variables are:
ST\$ \((49,1) \quad\) States and capitals array.
K Number of elements moved to top of list.
R1\% State pointer.
R2\% State or capital selector.
AN\$ Answer.
RT\% Number right.
WR\% Number wrong.
HE\% Number of helps.
I\$ Temporary string for exchanging data.

\section*{Arrays}

An array is simply an ordered set of data. It may have one or more dimensions. A one-dimensional array is merely a list whose data elements are numbered starting with 0 . For example, a grocery list of 20 items, numbered 0 to 19 , would be a one-dimensional array with 20 data elements.

To define an array, you must use a special type of variable called a subscripted variable. This takes the form AN(I), where AN
is the Array Name and I is the number (subscript) of the desired element. In our grocery list example, if \(\mathrm{I}=19\), then \(\mathrm{AN}(\mathrm{I})\) would be the last item on the list.

The array name may be any legal variable name, with \$ (string variable) or \% (integer variable) appended if appropriate. (This would indicate that the data contained in the array are strings or integers.)

Let's say you want a one-dimensional array with four elements. The four elements are integers (whole numbers): 21, 23, 25, and 27. The array would be represented by AN\%(I). That is to say, \(\mathrm{AN} \%(0)=21, \mathrm{AN} \mathrm{\%}(1)=23, \mathrm{AN} \mathrm{\%}(2)=25\), and \(\mathrm{AN} \mathrm{\%}(3)=27\).

A two-dimensional array is also an ordered list, but one whose elements are each an ordered list themselves. It's easier to understand if you picture it as a chart. For example, a two-dimensional array might look like this:
\begin{tabular}{|c|c|c|c|c|}
\cline { 2 - 5 } \multicolumn{1}{c|}{} & \(\mathrm{I}=0\) & \(\mathrm{I}=1\) & \(\mathrm{I}=2\) & \(\mathrm{I}=3\) \\
\hline \(\mathrm{~J}=0\) & 21 & 23 & 25 & 27 \\
\hline \(\mathrm{~J}=1\) & 43 & 45 & 47 & 49 \\
\hline \(\mathrm{~J}=2\) & 51 & 53 & 58 & 59 \\
\hline
\end{tabular}

A proper name for this array could be AN\% and its elements identified as \(\mathrm{AN} \%(\mathrm{I}, \mathrm{J})\). If \(\mathrm{I}=0\) and \(\mathrm{J}=0\), then \(\mathrm{AN} \%(\mathrm{I}, \mathrm{J})=21\). If \(\mathrm{I}=3\) and \(\mathrm{J}=2\), then \(\mathrm{AN} \%(\mathrm{I}, \mathrm{J})=59\). The advantage of arrays is that they let you store lots of numbers or other data without using lots of variables, and you can access any data element with a simple mathematical calculation. But be careful: arrays also consume big chunks of memory.

Arrays can become very complicated. It's easy to picture oneand two-dimensional arrays, but how about arrays of three or even four dimensions? Elements of three-and four-dimensional arrays are identified in the form \(\mathrm{AN} \mathrm{\%}(\mathrm{I}, \mathrm{J}, \mathrm{K})\) and \(\mathrm{AN} \%(\mathrm{I}, \mathrm{J}, \mathrm{K}, \mathrm{L})\), respectively.

\section*{Creating Arrays}

Typically, arrays are created with nested FORNEXT loops, each containing a READ from a DATA statement or an INPUT from a storage device. Each FORNEXT level creates one ordered list. For example, the following program could be used to define the contents of the two-dimensional array shown above:

10 DIM AN\% (3,2)
\(2 \varnothing\) FOR I=ø TO 3
\(3 \varnothing\) FOR J=ø TO 2
40 READ AN\% ( \(I, J\) )
5ø NEXT J
60 NEXT I
\(7 \varnothing\) DATA \(21,43,51,23,45,53,25,47,58,27,49,59\)
The inner (or nested) FOR/NEXT loop (lines 30-50) creates the ordered list of elements in the J-dimension within each element of the I-dimension. Compare the above chart to the DATA statement in line 70 to see how the array is set up.

The DIMension statement (line 10) is required to tell the computer how much memory to set aside for the array. Note that dimension sizes in a DIMension statement are one less than the number of elements in the dimension. The numbers of dimensions and the number of elements in each dimension are limited only by the amount of memory available.

Remember that an array can hold other types of data besides numbers. States \& Capitals Tutor uses a two-dimensional string array, ST\$(I,J), to store the 50 states and 50 capitals. See lines 10-35 in Program 2.

\section*{Storing Data}

Data can be added to a program by using DATA statements or keyboard inputs, or from data files stored on tape or disk. Tape or disk files work best when several programs must have access to the same data, or when a program needs several different data files, or when the amount of data you need to store exceeds memory capacity. Note that when arrays are filled from DATA statements, twice as much memory is required as when they are filled from tape or disk.

Storing and retrieving data is quite simple if you adhere to a few rules. First, before information can be written to or read from a file, a communications channel between the computer and recorder must be opened with the OPEN command. This tells the computer which file is involved and in which direction the information will flow (input from the recorder into the computer, or output from the computer to the recorder). If a write is indicated in the OPEN command, the computer will write a filename. If a read is indicated, the computer will search for the requested filename and then read the file.

Second, the file must be closed, after use, by the CLOSE command. This is especially important when creating a new file.

The third rule to watch when storing information on tape or disk is that variable types must be consistent. That is to say, data stored as numeric, integer, or string variables must be read back into variables of the same type. The variable names themselves are not stored, so they can be read back into entirely different variables, as long as you don't mismatch types.

Fourth, data is read back in the same order in which it was written. Therefore, the program must expect the data in exactly the same order in which it will be received.

\title{
Mystery Spell
}
(Figure 3). Using those shapes, we designed three more birds identical to the first three, but without legs. This gave us three frames for the bird carrying a letter, and three frames for the bird flying freely. We then set up the DATA statements in the program as if we were going to display six different sprites.

Immediately after the screen RAM are eight memory locations that tell the 64 where in memory to find the shapes of the eight sprites. Usually these locations are at 2040 to 2047 (\$07F8 to \(\$ 07 F F\) ). By rapidly POKEing 2040 with the pointer to each frame, the bird seems to flap its wings. To see how this is done, look at lines 2000-2060. This is the routine which flies the bird around the top of the screen until you press a key. Line 2050 steps through the frame numbers. The actual POKEing is done at the end of line 2000.

Another interesting feature of the game is that when you guess correctly, the bird swoops down to pick up a letter, and then carries it up to the word. How is that letter incorporated into the bird sprite?

In the character set ROM at 53248 (\$D000), the shape of each character is contained in eight bytes. Each byte is one row, and each bit is a column within that row. Depending on whether the value of that bit is 0 or 1 , the pixel will be clear or set inside the character. The sprite is 24 bits wide, which is as wide as three characters. This means that by putting character shape data into every third byte within a sprite, we can make character shapes inside sprites. This technique could be used in any program which moves letters or text around smoothly. To see how this is done, look at lines 2180-2260.

Lines 2180 and 2190 make the character ROM available to be PEEKed. They also turn off the keyboard. Lines 2200 to 2240 take the character data and put it in the sprites. Finally, lines 2250 and 2260 cover up the character ROM and reenable the keyboard.

\title{
Oil Tycoon
}

\author{
Gordon F. Wheat 64 Translation by Chris Metcalf
}

You are P. J. Uing and you are about to make big money in the petroleum business, but drilling for oil is not as easy as it sounds. There are obstacles you must overcome in order to make a profit. There are shale formations that grind away your pipe. You can blast through them, but your dynamite is limited. Pockets of natural gas sometimes collect where you have previously pumped out the oil. Hit one of these and your oil rig goes up with a bang. There are also "devils" that live in the oil. They take a dim view of your draining their caverns. But you won't give up-because you are the Oil Tycoon.

I designed "Oil Tycoon" to be as much fun for parents as it will be for children. Since the game is not based on reaction time but rather on strategy, it helps even the score for the arcade dropouts. Your strategy will slowly build, and before long you will be rolling in cash or attaining high scores, however you wish to look at it.

\section*{Difficulty Levels}

The screen will display the high scores attained for each of the eight difficulty levels. The program will return to this screen after each game. Your score and the difficulty level of the game you have just completed are displayed at the top of the screen.

At the bottom of the screen you will see "DIFF . LEVEL 12345678." Choose the difficulty level by moving the joystick left and right and pressing the fire button when the number of the difficulty level you want is blinking. Level one is primarily for small children. I would recommend that seasoned gamers begin with level two. The higher the difficulty level, the more difficult the game becomes. The various conditions for the eight difficulty levels are shown in the table.

\section*{Difficulty Levels}
\begin{tabular}{cccc} 
Level & \begin{tabular}{c} 
Sticks of \\
Dynamite per \\
Oil Rig
\end{tabular} & \begin{tabular}{c} 
Pieces \\
of Shale
\end{tabular} & \begin{tabular}{c} 
Invisible \\
Shale
\end{tabular} \\
1 & 3 & 20 & No \\
2 & 2 & 20 & No \\
3 & 3 & 30 & No \\
4 & 2 & 30 & No \\
5 & 4 & 20 & Yes \\
6 & 3 & 20 & Yes \\
7 & 4 & 30 & Yes \\
8 & 3 & 30 & Yes
\end{tabular}

\section*{Playing Oil Tycoon}

After you choose the level, the oil field is drawn on the screen. It will be different for each game; you should never see the same screen twice. For each game, you receive five oil rigs, each of which has 20 lengths of pipe and a number of sticks of dynamite, depending on the difficulty level you choose.

In the upper-left corner of the screen are the oil rigs you have remaining. In the upper-right corner is your score. Between these are the sticks of dynamite you have remaining for the oil rig now in play. The second line displays the unused lengths of pipe for the oil rig now in play. As you drill, this pipe will be used one length at a time and will be replaced as you withdraw your drill. The lower portion of the screen is the playing field. Yellow squares are dirt, black squares are oil, and the irregular squares are shale.

Move the joystick left and right to position your oil rig over the column you want to drill through. To drill, pull the joystick down. To withdraw the drill, push the joystick up. You cannot move the oil rig while there is drilling pipe in the ground. You cannot bore through shale, through devils, or off the bottom of the screen. If you try, your drill will be ground up, and you will lose that length of pipe for the oil rig in play. This becomes very important in difficulty levels above four, for the shale is invisible and looks like dirt. At these levels, it is very easy to lose most of your drilling pipe before you realize that you are trying to drill through shale. Also try to avoid drilling through empty spaces from which you have previously pumped oil. Natural gas can collect in these empty spaces and may cause an explosion when you try to drill through them again.

Controlling the fire button takes some getting used to, because it does three things. As you bore, if the end of the drilling pipe is in oil or an empty space, pressing the fire button causes your oil rig to start pumping. If the end of the pipe is in dirt, pressing fire drops a stick of dynamite down the pipe. If you are not drilling, or if you have fully withdrawn the pipe, pressing fire replaces your current oil rig with one of your remaining rigs. Be careful-it is easy to lose valuable rigs. Replacing your oil rig with a new one is useful mainly when you have used up your allotted dynamite for the rig in play, or if you do not have enough pipe remaining to reach pools of oil near the bottom of the screen.

Use your dynamite to blow up shale, devils, or dirt. When you drop dynamite down the pipe, it will continue to fall until it hits one of these three obstacles. This means that if there is oil or empty space directly below the tip of the drill, the dynamite will fall out of the bottom of the pipe and through this space until it hits shale, a devil, or dirt.

\section*{Pumping Oil}

When you pump, all of the oil in adjacent spaces to the sides and above the level of the drill bit will be pumped out. In other words, all squares of oil connected to the one you are pumping will also be pumped out only if they lie directly above or to the sides of the oil being pumped. Any squares of oil below those which are being pumped out will remain where they are.

If you uncover a devil while pumping, it will blow up your oil rig. If you try to pump a pool of oil which is at or below the level of an uncovered devil, and which is directly connected to the devil's space, it will also blow up your rig.

The deeper the oil, the more it is worth when you pump it out. An extra oil rig is awarded for each \(\$ 100,000\) you acquire. In addition, if you pump out all the oil on the screen and then retract your pipe, you will be awarded an extra oil rig and a new screen is drawn.

\title{
Mosaic Puzzle
}

\section*{Bruce Jordan 64 Translation by Chris Metcalf}

This adaptation of an old favorite will challenge your reasoning powers.
"Mosaic Puzzle" is a computer version of those sliding-squares puzzles that used to drive people nuts before the advent of Rubik's Cube. The object of the game is to arrange the 15 squares into some predetermined order by sliding them around in their frame. The first few moves are easy, but as the game progresses, it gets a lot more complicated. You'll find yourself rearranging everything just to get the last few squares in place.

The game has a timer for up to 23 hours, 59 minutes, 59 seconds, and a chicken switch. It also automatically checks for the winning order and allows you to go back to the puzzle the way you left it or reset it to the beginning arrangement.

When you start the game, you're asked if you wish to set a time limit. If you answer \(Y\) for yes, enter the time limit in one line with no spaces or punctuation between the values. For example, for a 1-hour, 23-minute limit, enter 012300.

Next, enter the goal order. This will be the order that you will try to match to win the game. When this is done, the upper half of the screen will clear, and the puzzle will appear.

Either the RETURN key or the fire button allows you to pause momentarily before resuming the game, restarting the program, or stopping play entirely. Breaking off and resuming has no effect on the time clock (displayed at the top of the screen along with the time limit).

As an aid to the user, various keys for up, down, right, and left can be selected at the beginning of the game. A joystick can also be used, as long as it is plugged into control port two. The time limit is an option in this version; if no time limit is selected, the screen will display elapsed time and TIME LIMIT: NONE.

If you succeed in getting the squares in the goal order, the message YOU WIN! appears on the screen, accompanied by a short tune and the elapsed time. If the time runs out before you are finished, you'll hear an unpleasant sound.

\title{
Blockhead
}

\author{
Matt Giwer 64 Version by Gregg Peele
}

Here is a challenging game for the whole family. See how many balloons the blockhead can pop in the allotted time. Requires game paddles.
"Blockhead" is a colorful game similar to some of the early arcade games. It is simple to play, and will especially appeal to young children, who will like the clever use of sound and color in the game. The program makes good use of the Commodore 64's graphic capabilities, for it utilizes the eight available sprites and even includes a machine language routine. This interrupt-driven routine provides optimal motion in the game, as well as monitors the position of the sprites.

Once you have the program typed in, SAVEd, and LOADed, you can see that the machine language routine still operates, even if the BASIC part of the program does not. LOAD and RUN Blockhead, then press RUN-STOP. This breaks the BASIC program, but the blockhead can still be moved with the paddle control.

Blockhead uses the collision register to detect when one sprite touches another. Since the collision register is changed only temporarily when sprites collide, the contents representing the collision must be saved until an event occurs which may again make the sprite collide. The register is then cleared, and the sprite is ready for collision. Collision detection between the blockhead and balloons is handled through BASIC.

The game is played with a set of paddles, which must be plugged into Control Port 1. Since Blockhead is a one-player game, only one paddle will work. The paddle moves the blockhead's home base from side to side, with the blockhead standing on it. You use the fire button on the paddle to make the blockhead leap.

The original version of this game is written to be used with Atari-style paddles. If you have Commodore paddles, you must change lines 1070 and 1080 to read as follows:

Dexterity

This alteration leaves a slight glitch in the paddle movement around the seam but provides for optimal range for movement around the screen.

\section*{Playing the Game}

This game works using a timer. The object of the game is to pop the balloons as they float across the sky. The more balloons you pop in the time limit of two minutes, the more points you'll receive. Not only must you pop the balloons, but you must also catch the blockhead before he falls below his home base. If you miss catching him, points are deducted until you bring him to the surface by pressing the fire button. He'll then leap back into the air.

For each balloon that you pop, you receive 10 points. Each time you drop the blockhead, your score is reduced by 15 points.

When you LOAD and RUN the program for Blockhead, a tune plays and the screen sets up. This takes a few moments, so be patient. Finally, the blockhead appears, and the balloons begin to float across the sky. At first, they are close to the ground and easy to pop. Simply press the fire button and the blockhead leaps into the air. If he touches a balloon, it disappears, and you'll hear a soft popping sound. You've just received ten points. The balloons will continue to float at this level until all six of them are popped by the blockhead.

As soon as the first level of balloons has been popped, the tune plays again, then another level, slightly higher, appears from the left side of the screen. There are six levels of balloons altogether. If you pop all the balloons, 36 in all, the game stops, even if there is time remaining. At this point, you're asked if you want to play another game.

Of course, popping the balloons is only half the fun. You also have to catch the blockhead as he drops to the ground. If you miss him with the paddle-controlled base, he will vanish. To make him reappear, you need to press the fire button to make him leap back up.

\section*{Going for the High Score}

After playing Blockhead a few times, you'll notice some things that can increase your score, or reduce the time it takes you to pop all the balloons.

If you time the blockhead's leap, you can pop two balloons at once. This must be precise. The blockhead has his hands out-
stretched, and if both come in contact with a balloon at the same time, the balloon on either side will pop. Sometimes this works, and other times it doesn't.

You can also receive points if the blockhead comes very close to a balloon. The balloon won't pop, but you'll hear the popping sound, and another ten points will be added to your score. Just as with trying to pop two balloons at once, this will not work all the time.

If you keep the blockhead's home base stationary, most of the time he will fall back to it. Not always, so you have to keep your eye on him.

Remember that the blockhead is not able to pop a balloon on the way down, only on the way up.

\title{
Diamond Drop
}

Catch the falling diamonds-if you can. This fast-action game is easy to play.
"Diamond Drop" is a game that requires good judgment and quick reflexes. It's fast and easy to play. To insure fast action, it is written predominantly in machine language. BASIC is used only to print instructions, set up the display, select the skill level, and initiate the drop.

The game display starts with six rows of objects at the top of the screen and a stack of six catching trays at the bottom. As the objects begin to drop, you must use the \(L\) and ; keys to maneuver the trays and catch the objects. To make play more challenging, one tray disappears whenever the last ball drops from a row. Thus, you have only one tray with which to catch objects from the last row. When all the objects have dropped, you start again with six rows of objects and six trays. Play continues until a total of five objects hit the ground.

Since the DATA statements comprise the machine language program for the game, it is essential that they be typed correctly. Be sure to SAVE a copy of the program before you attempt to RUN it, since an error in typing may cause your computer to lock up, forcing you to turn the power off to recover. If Diamond Drop fails to RUN properly, the problem will most likely be a mistyped number somewhere in the DATA statements, so check carefully.

\title{
Laser Bounce
}

\section*{Frank L. Broadnax}

Don't let the ball get by you. The longer you can chip away at the bricks, the higher your score.
"Laser Bounce" is a game of movement and trajectory similar to some of the earlier videogames. Using only the character set provided with the Commodore 64, it displays a spaceship, the laser balls which rebound from the ship, and the walls of energy you are trying to break through.

Played with a joystick plugged into Control Port 2, the game begins with a simple title screen and a short musical introduction. At that point you're asked if you want to read the instructions before the game. If this is your first game, you would press Y , and the instructions appear. Once you've played the game, however, you can press N and go directly to the screen setup.

The screen sets up quickly, with the present and high scores displayed at the top, your spaceship in the middle, and the six colored energy walls below. The number of spaceships remaining is indicated by the small circles near the top-right-hand corner of the display.

As soon as the screen is completed, the game begins. Your spaceship fires its laser, and the ball appears. The ball will travel in one of four directions to start the game. It will move up and to the right, up and to the left, down and to the right, or down and to the left. Be especially watchful for the ball to move up, toward your spaceship, for you won't have much time to intercept it.

Intercepting the laser ball makes it rebound and move toward the energy walls or the side of the screen. It will bounce off both, but you'll receive points only if it hits the wall and eliminates a brick. Ten points are awarded for each gap created.

Although it doesn't matter which part of the ship the ball touches, it's best to use its center. Sometimes you may think you're in the right position, but the ball misses one wing of the ship and gets by you. Unlike other games of trajectory, the ball will not bounce at a different angle depending on where it strikes
the ship. No matter where the ball touches the spaceship, it will simply rebound.

The ship moves rather slowly, so it's a good idea to keep track of the ball, especially when it gets trapped in the wall and is busy eliminating bricks. You should be able to tell when the ball will escape from the wall and head back toward you. Anticipating it is important: if your spaceship is out of position, it will be hard to recover in time to intercept. Because the spaceship moves three columns at a time, its movement is sometimes jerky, and can make it seem like the spaceship is changing position faster than it actually is.

The laser ball is also hard to keep track of at times. Because it is drawn and erased each time it moves, it blinks off and on.
However, when it erases bricks from the energy wall, it seems to disappear for a moment. If it is eliminating bricks rapidly, the best way to keep track of it is to watch the pattern of erasing bricks. Plotting where it will return toward your ship, you can move to that position.

If you miss intercepting the ball, and it gets by you, your spaceship will reappear in the middle of the screen, fire its laser, and another round begins. You have a total of five spaceships during a game, the number remaining indicated by the display.

If you erase all five energy walls, the game isn't over. Another five walls are drawn when you reach 4800 points, the total you should have after eliminating all the bricks. Each time all five walls are erased, another five appear to take their place. You receive no additional spaceships, however.

As the game ends, a message appears asking if you want to play another game. Pressing Y sets up another screen after you've indicated whether you need to read the instructions again. The score will return to 0, but the previous high score remains as long as the computer is left on. The high score only prints once a ball is missed. You can quit playing simply by entering N when the prompt appears at the end of a game.

\section*{Laser Bounce Variations}

It's easy to create several variations of this game simply by altering a few of the program lines.

An interesting variation can be created by changing line 400. Instead of the value \(D Y=-D Y\), insert \(D X=-D X\). This will make the laser ball wind its way down through the energy walls, reappearing and moving toward the spaceship only after it's erased its way free.

Another change can be made in lines 460 and 470. Insert GOTO 310 instead of GOTO 320. After a ball is missed, the energy screens will be redrawn, in effect making you start over. Your score will not return to 0 , however.

Changing the value of DX in line 335 will also create another variation of Laser Bounce. DX \(=2\) will alter the angle at which the ball rebounds. This can make the ball difficult to intercept, especially as the game begins and the ball moves up and to one side. You'll have to be fast to intercept it before it gets by you.

\section*{Programmer's Notes}

It may be useful to outline some of the major subroutines of this game program so you can see how it all fits together.
\(\left.\begin{array}{ll}\text { Lines } & \begin{array}{l}\text { Function } \\ \text { Sen up the title screen and send the program to the }\end{array} \\ \text { s-170 } \\ \text { subroutine which plays the opening music. } \\ \text { Begin the setup of the game instructions, and send the } \\ \text { program to the subroutine at 35000, which contains the } \\ \text { rest of the game description. }\end{array}\right\}\)

\title{
The Hawkmen of Dindrin
}

\section*{Esteban V. Aguilar, Jr. 64 Version by Charles Brannon}

\begin{abstract}
Fly down through the dangerous skies of the planet Dindrin to collect stones. Retrieve enough of them and win the game, but beware of the floaters and lizards. Several special techniques are used in this game, including animation, multicolor sprites, and sound effects, each of which is explained in the article.
\end{abstract}

There's a strange planet named Dindrin where multicolor floaters and a giant sky skimmer drift through the daytime skies. On the surface of the planet, vicious land hunters come up from the ground and set polished golden stones in the sun. It's a form of worship too obscure, too alien to describe.

Suddenly a strange-looking hawk-like creature dives down and snatches a stone. You are the hawkman. Your objective is to pick up the golden stones.

Several special programming tricks went into this game. When you have the game running, watch the screen carefully. A patrol snake sweeps across the bottom of the screen. Airborne floaters pop up all over the screen. The hawkman's wings flap. The luminous stones at the bottom of the screen are protected by menacing lizards whose tongues wiggle venomously at you.

To play the game, use a joystick plugged into the first port. Maneuvering is accomplished by pulling left on the joystick to go backward. Whenever you want to dive or fly upward, you must pull down or up (respectively) on the stick. One thing to keep in mind when ascending or descending is that you will move diagonally rather than straight up or down.

The joystick response will be strange and difficult to master, but predictable. Once in a while, an obstacle such as a floater will get in your way; press the fire button to safely bump into the obstacle (and get points for it).

There are a couple of things to consider before playing the
game. As time passes, you will lose energy, If your energy runs out, you will lose a life. Second, when you're flying, don't run into anything or you'll lose one of your lives. When all your lives are lost, the game is over.

\section*{How It's Done}

Multicolored characters are used for the stones and the lizards.
The patrol snake is a multicolored sprite.
The animation (wing flapping, tongue wiggling) is done by switching between two custom character sets. Every object to be animated has two alternate views. The same image is copied into both character sets for shapes that should not move, such as the stones or the score line.

A machine language routine is used for smooth, even horizontal motion for the patrol snake. Instead of being called when needed by BASIC, the machine language routine runs continuously in the background. The machine language routine also flips the character set.

\section*{Interrupting the Commodore 64}

We used the hardware interrupt request (IRQ). To place a machine language routine so that it automatically executes every 1/60 second, you change the IRQ vector at \$0314 (it normally points to the ROM interrupt routines) to point to your machine language routine. After your routine executes, it exits with a JMP to the normal ROM routine.

The setup is a little tricky. While you're storing the new IRQ value, you have to use SEI (SEt Interrupt disable bit) to prevent any interrupts from happening. If you don't, an interrupt could occur after you had stored the first byte of the vector value but before you changed the second. The interrupt would then vector through a "half-baked" value, and end up in limbo.

After you've changed the IRQ vector, you clear the interrupt disable bit (CLI) and return with RTS to BASIC. The machine language routine will then be running continuously in the background, flipping the character set and moving the sprite.

\section*{Multicolor}

Multicolor graphics are important for good arcade effects. A few years ago, graphic objects (such as a tank or plane) were always a single color. But increasing realism has been a feature of arcade graphics, and multicolored objects are an important aspect of this realism.

Normally, when you define a custom character set, you create eight rows of pixels (picture elements, dots). Each row is eight dots (or bits) wide. With multicolor, each row is divided up into four two-bit pairs. Each pair of bits can hold a number from 0-3: \(00,01,10,11\). You use a different number for each color. This reduces the resolution to four multicolor pixels per row, so the lizards and stones are composed of two characters each. You also have to tell the VIC-II chip that you are using multicolor. Do this with:

\section*{POKE 53270, PEEK (53270) OR 16}

Disable multicolor with:
POKE 53270, PEEK (53270) AND 239
Here is a sample multicolor shape:
\begin{tabular}{ll} 
rrrr & \(r=\) red (arbitrary colors) \\
rbbb & \(b=b l u e\) \\
rbgg & \(g=\) green \\
rbgg &
\end{tabular}

Let's say the binary codes for red, green, and blue are (respectively) 01,10 , and 11 . Substituting gives:
\begin{tabular}{lllll}
01 & 01 & 01 & 01 & 01010101 \\
01 & 10 & 10 & 10 & 01101010 \\
01 & 10 & 11 & 11 & 01101111 \\
01 & 10 & 11 & 11 & 01101111
\end{tabular}

You can change the colors according to this key:
00 Background \#0 color register - 53281
01 Background \#1 color register - 53282
10 Background \#2 color register - 53283
11 Color in lower 3 bits in color memory.
That last line needs explaining. You know that to get variously colored characters, you POKE a number from 0-15 into the corresponding color memory location. However, colors 8-15 (accessed by the Commodore key) are really multicolors. Multicolor characters always are displayed with a color from 8-15. You won't get the eight alternate colors (such as gray), but the normal color on the key ( \(15=\) yellow). Just add eight to the normal color number. So, a bit value of 11 will take on the value in color memory. The other colors will come from the color registers ( 00 is transparent).

Multicolored sprites are similar. Instead of the normal 24-bit resolution, the bits are grouped into 12-bit pairs. The colors come from:

00 - Transparent, screen color
01 - Sprite multicolor register \#0 53285
10 - Normal sprite color register
11 - Sprite multicolor register \#1 53286
You tell the VIC-II chip that you are using a multicolored sprite by:

POKE 53276, PEEK (53276) OR (2 \(\uparrow\) X)
\(X\) is the sprite number, from 0 to 7 . You can mix multicolored and regular sprites on the same screen. But all multicolored sprites will share the same two multicolor registers.

\section*{Simple SID Chip Sound}

The "thrumming" noise is made by playing a low-pitched tone through the SID using the variable pulse wave and a fairly long (one-second) decay. Another sound effect (I can't really describe it) is made with white noise and a medium decay. The high byte of the pitch is changed as the note is played. There is also another sound effect created by the sawtooth waveform affecting the low byte of the pitch.

\title{
Minefield
}

Sean Igo 64 Translation by Gregg Peele

Your job is to get your trucks in quickly, defuse the bombs (especially the flashing ones which are about to go off), and get out as fast as you can. This game has four skill levels.

In this game, you drive a truck around to gather and defuse time bombs before they explode-all the while avoiding mines and bomb craters.

\section*{Playing the Game}

You find yourself in the center of a small minefield with several bombs, represented by circles, and a generous number of mines, shown as X's. Your truck is a diamond. To defuse the bombs, just run over them with the truck.

When the bombs first appear, they are innocent-looking little circles. After a short time-the rate varies from bomb to bombthey turn reverse-field. This means watch it. Soon they begin to blink, and you have only a few blinks to defuse them before they explode. Any mines (or heroic defusing teams) caught in the explosion will be instantly lost. Bombs caught in the explosion will explode, whether they were ready to or not.

Your truck can move in only four directions. It can wrap around all four edges of the screen. Don't run it into the mines or the craters ( \({ }^{*}\) ) left by the bombs or your truck will be destroyed. Once you begin moving, your truck cannot stop until it is blown up or until the current minefield is cleared of bombs.

\section*{Skill Levels and Scoring}
"Minefield" has four skill levels. Skill levels differ only in the number of trucks you get. Level 0 , the easiest, has four trucks. Level 1 has three. Level 2 has two, and level 3 has one.
Scoring: 10 points for a normal bomb 20 points for a reverse-field bomb
30 points for a blinking bomb
-10 points at the end of an explosion for every bomb that went off. This is incentive to defuse more than one or two bombs in the later explosions.

\section*{5}

\section*{Cylon Zap}

Mark Dudley 64 Translation by Gregg Peele

\section*{Quick reflexes are what you'll need for this fast-action game.}
"Cylon Zap" is an arcade-style game. A space station in the center of the screen, which you must defend at all costs, is attacked continually by Cylon ships. You must shoot them before they dive (kamikaze style) into the space station.

To defend against the Cylons, you have two weapons. First, the joystick is moved up, down, right, or left to fire lasers in any of these four directions. Second, the fire button detonates a smart bomb, which immediately clears the screen of all visible attackers. Smart bombs should be used sparingly, for only three are available at the beginning of play.

The score and the number of remaining bombs are continually updated at the upper-left corner of the screen. When the score reaches 30 , the flank attackers begin to increase speed. When your score reaches 50 , the attackers from the top and bottom increase their speed. If your score exceeds 60 , you win bonus smart bombs.

If your point total is a high score since the program was first loaded, you enter your initials with the joystick. Moving the stick right or left lets you step through the alphabet forward or backward. When you find the correct letter, select it with the fire button. Be sure not to hold the fire button down too long when selecting your initials, or you may inadvertently choose the wrong letters.

\title{
Laser Gunner
}

Gary R. Lecompte 64 Translation by Philip I. Nelson

This arcade-style game achieves an impressive graphics animation without the use of any machine language.
"Laser Gunner" is an arcade-type action game. The player controls a laser gun which moves up and down on the left of the screen behind a force field and fires at invading enemy spaceships. The invaders also fire lasers and attempt to open holes in the force field. Every hit weakens the force field until an entire hole is made. A hit through a hole ends the game.

Laser Gunner is an example of animation accomplished without the use of machine language routines. The drawback of this type of programming is obvious. Only one string may be animated at a time with any speed. However, by working your game format around this limitation, you can still make action games fast and challenging.

The animation of the laser gun and the position of laser fire, as well as the location of the invaders, are controlled by the location routines. The row and column values are POKEd into memory locations 214 and 211. A PRINT statement following these routines will print that string beginning at the location determined by the row and column values. Changing the row and column values and printing the same string again accomplishes animation.

The force field changes are made by PEEKing the location of the hit, determining the character at that location, and POKEing the value of the next character to that location.

Invader explosions are done by coding cursor movements and printing characters from the invader string.

Sound routines are intermixed with laser and explosion routines. This assures that animation and sound will blend.

Invader ship location and laser fire are determined by randomizing routines. Skill level is provided by giving the player a minimum preset delay. Actual time before invader laser blasts is always unpredictable.

Stars are created with simple POKE statements to predetermined locations.

All routines are placed in order of importance, with those used most at the beginning. This allows for the fastest program execution possible to increase animation speed. REM statements should be deleted for best effect. The key to speed is simplicity. The shorter the program statements, the greater the speed.

\section*{Changing the Shapes}

It is possible to change the shape of the ships. Lines 85 and 86 contain the statements which produce the shape. To make your own ships, you can use any graphic symbols from the front of the 64 keyboard. Pick the characters you want, and substitute them for the shifted characters within the quotes for IN\$, G1\$ and G2\$ in lines 85 and 86 . Remember, you get the left-side graphic character by holding down the Commodore key rather than SHIFT.

Machine
Language Games

\title{
Using the Machine Language Editor: MLX
}

\section*{Charles Brannon}

Three of the games in this chapter are written completely in machine language. The "Machine Language Editor" will make typing a perfect copy of those games a snap.

Remember the last time you typed in a long machine language program? You typed in hundreds of DATA statements, numbers, and commas. Even then, you couldn't be sure if you'd typed it in right. So you went back, proofread, tried to run the program, crashed, went back and proofread again, corrected a few typing errors, ran again, crashed, rechecked your typing . . . . Frustrating, wasn't it?

Until now, though, that has been the best way to enter machine language into your machine. Unless you happen to own an assembler and are willing to wrangle with machine language on the assembly level, it is much easier to enter a BASIC program that reads the DATA statements and POKEs the numbers into memory.

Some of these BASIC loaders will use a checksum to see if you've typed the numbers correctly. The simplest checksum is just the sum of all the numbers in the DATA statements. If you make an error, your checksum will not match up. Some programmers have made your task easier by creating checksums every ten lines, so you can zero in on your errors.

But MLX comes to the rescue! The "Machine Language Editor" (MLX) is a great way to enter all those long machine language programs with a mininum of fuss. MLX lets you enter the numbers from a special list that looks similar to BASIC DATA statements. It checks your typing on a line-by-line basis. It won't
let you enter illegal characters when you should be typing numbers. It won't let you enter numbers greater than 255 . It will prevent you from entering the wrong numbers on the wrong line. In short, MLX will make proofreading obsolete.

\section*{Boot Disks}

In addition, MLX will generate a ready-to-use tape or disk file. You can then use the LOAD command to read the program into the computer, just like any other program. Specifically, you enter:

LOAD "program", 1, 1 (for tape)
or
LOAD "program", 8, 1 (for disk)
To start the program, you need to enter a SYS command that transfers control from BASIC to machine language. The starting SYS will always be given in the appropriate article.

\section*{Using MLX}

Type in and save MLX (you'll want to use it in the future). When you're ready to type in the machine language program, RUN MLX. The program will ask you for two numbers: the starting address and the ending address. Below is a table that lists this information for each of the games that use MLX.

\section*{Starting and Ending Addresses}
\begin{tabular}{llll} 
Game & Start address & \begin{tabular}{l} 
End address \\
Munchmaze \\
Richthofen's \\
Revenge
\end{tabular} & \begin{tabular}{l}
12288
\end{tabular} \\
\begin{tabular}{l} 
Command to Run
\end{tabular} \\
Zuider Zee & 49152 & 5817 & \begin{tabular}{l} 
SYS 12311 \\
RUN or SYS 2063
\end{tabular} \\
& 42049 & 52040 &
\end{tabular}

Once you have entered the starting and ending addresses, you'll get a prompt to start entering the data. The prompt is the current line you are entering from the listing. Each line is six numbers plus a checksum. If you enter any of the six numbers wrong, or enter the checksum wrong, the 64 will ring the buzzer and prompt you to reenter the line. If you enter it correctly, a pleasant bell tone will sound, and you go on and enter the next line.

\section*{A Special Editor}

You are not using the normal Commodore 64 editor with MLX. For example, MLX will accept only numbers as input. If you need to make a correction, press the <INST/DEL> key; the entire
number is deleted. You can press it as many times as necessary to get back to the start of the line. If you enter three-digit numbers as listed, the computer will automatically print the comma and go on to accept the next number. If you enter less than three digits, you can press either the comma, space bar, or RETURN key to advance to the next number. The checksum will automatically appear in inverse video; don't worry-it's highlighted for emphasis.

When testing it, I've found it to be extremely easy to enter long listings. With the audio cues provided, you don't even have to look at the screen if you're a touch-typist.

When you get through typing, assuming you type it all in one session, you can then save the completed and bug-free program to tape or disk. Follow the screen instructions. If you get any errors while writing, you probably have a bad disk, or the disk was full, or you made a typo when entering the MLX program. (Sorry, it can't check itself.)

\section*{Command Control}

What if you don't want to enter the whole program in one sitting? MLX lets you enter as much as you want, save the whole schmeer, and then reLOAD the file from tape or disk when you want to continue. MLX recognizes these few commands:

\section*{SHIFT-S: Save \\ SHIFT-L: Load \\ SHIFT-N: New Address \\ SHIFT-D: Display}

Hold down SHIFT while you press the appropriate key. You will jump out of the line you've been typing, so I recommend you do it at a new prompt. Use the Save command to save what you've been working on. It will write the tape or disk file as if you've finished, but the tape or disk won't work, of course, until you finish the typing. Remember what address you stop on. The next time you RUN MLX, answer all the prompts as you did before, then insert the disk or tape. When you get to the entry prompt, press SHIFT-L to reLOAD the file into memory. You'll then use the New Address command to resume typing.

\section*{New Address and Display}

After you press SHIFT-N, enter the address where you previously stopped. The prompt will change, and you can then continue typing. Always enter a New Address that matches up with one of the line numbers in the special listing, or else the checksum won't
match up. You can use the Display command to display a section of your typing. After you press SHIFT-D, enter two addresses within the line number range of the listing. You can abort the listing by pressing any key.

\section*{Tricky Stuff}

The special commands may seem a little confusing, but as you work with MLX, they will become valuable. For example, what if you forgot where you stopped typing? Use the Display command to scan memory from the beginning to the end of the program. When you see a bunch of 170s, stop the listing (press a key) and continue typing where the 170s start. Some programs contain many sections of 170s. To avoid typing them, you can use the New Address command to skip over the blocks of 170s. Be careful, though; you don't want to skip over anything you should type.

You can use the Save and Load commands to make copies of the completed game. Use the Load command to reLOAD the tape or disk, then insert a new tape or disk and use the Save command to create a new copy.

One quirk about tapes made with the Save command: when you load them, the message "FOUND program" may appear twice. The tape will load just fine, however.

Programmers will find MLX an interesting program, in protecting the user from mistakes. There is also some screen formatting. Most interesting is the use of ROM Kernal routines for LOADing and SAVEing blocks of memory. Just POKE the starting address (low byte/high byte) into 251 and 252, and POKE the ending address into 254 and 255. Any error code can be found in location 253 (an error would be a code less than ten).

I hope you will find MLX to be a true labor-saving program. Since it has been tested by entering actual programs, you can count on it as an aid for generating bug-free machine language.

\title{
Munchmaze
}

\author{
Gary E. Marsa 64 Translation by Gregg Peele
}
"Munchmaze" is a fast-action strategy game. Since it is written in machine language, it requires the use of the Machine Language Editor (MLX) for mistake-proof entering.

The character in "Munchmaze" hurries through the maze dropping bread crumbs as it goes. You move your character around by using the \(I, J, K\), and \(M\) keys trying to munch up as many of the bread crumbs as you can before the character catches you. The game ends when the two characters collide or when you accumulate 10,000 points.

There are three speed levels: slow, moderate, and fast. Both characters move at the same speed, but the computer character beats you on the corners. Also, you have to change directions manually; it doesn't. The computer character always goes left if it can; it's helpful to remember this when you are looking for a temporary hiding place.

There's another tricky feature, too. Sometimes, when the two characters are moving from opposite directions toward each other, the computer character goes right on by and no collision occurs. Just breathe a sigh of relief and continue munching-you were lucky.

The maze in Munchmaze is not constructed on the screen, but in another area of RAM. It is then transferred to the screen, where it appears all at once; then there is a one-second delay before the action begins. If you break out of the program for any reason, just type SYS 12331 and RETURN to restart.

\section*{Typing in Munchmaze}

This program is written entirely in machine language, so it is necessary to enter it using the Machine Language Editor (MLX) found at the beginning of this chapter. Be sure to read the directions for using the MLX.

The information needed to enter Munchmaze with the MLX is:

Starting address: 12288
Ending address: 13956
Once Munchmaze is saved to disk or tape, the procedure for loading the program is as follows:

From disk: type
LOAD "MUNCHMAZE", 8,1
From tape: type
LOAD"", 1,1
When the program is loaded into memory, type SYS 12311 to run it.

\section*{Munchmaze}

\title{
Richthofen's Revenge
}

\author{
Chris Metcalf Marc Sugiyama
}

> "Richthofen's Revenge" is an arcade-style game that even the most experienced game players will find challenging. This program requires special care to enter correctly; please see the section "Typing in the Program."

The airborne forces of Richthofen, the dreaded Red Baron, have been mobilized. Because of your reputation as a swift pilot and accurate gunner, you have been chosen to defend the front line. Only a few planes are available, with no time to build more. Prepare yourself to meet the hordes of Richthofen.

As you encounter each succeeding wave of the enemy, another airplane will be delivered to the front. Once all the planes have been destroyed, however, there will be nothing to stop the enemy from an all-out invasion. Your skills are all that stand between Richthofen's forces and your country.

\section*{Typing in the Program}

This program is written entirely in machine language, so it should be entered using the Machine Language Editor (MLX) found earlier in this chapter.

The steps to typing in a machine language program using MLX are simple, but they must be followed exactly in order to get a playable copy of the game. Once you have a copy of "Richthofen's Revenge" saved on disk or tape, you will be able to LOAD and RUN it just as you would any BASIC program even though it is machine language.

The steps for typing in Richthofen's Revenge are:
1. Reset the computer by turning it off, then back on.
2. Type this line:

POKE 44,23:POKE 23*256,0:NEW
3. LOAD the Machine Language Editor into memory. (If you have not typed in and SAVEd MLX, you will have to do that first.)
4. RUN the MLX program.
5. Answer the prompts

START ADDR: 2049
END ADDR: 5817
6. Type in the data.
7. MLX will prompt you for a filename.
8. Before you load the program, reset the computer.

That's all there is to it. It is not necessary to type in all the data in one session. The instructions for using MLX are at the beginning of this chapter. If you do decide to enter the data in more than one session, it will be necessary to follow the above steps each time you begin a session.

\section*{Preparing for Battle}

When you first RUN the game, the screen will come up with a landscape, a status line, and the message RICHTHOFEN'S REVENGE. The information given in the status line is the high score, the score of the current game, and the number of backup planes remaining. A short tune will play to prepare you for the combat.

When the message PRESS FIRE TO BEGIN appears, you may begin playing or move to a higher level. By moving the joystick up or down, you can pick any level from 1 to 30. Levels 31 through 40 are reserved for expert players, and the levels above that are only for the true masters.

Once you have selected a level, or at any point after the music begins, you may press the fire button and begin playing. Every time you enter a level, or when a new plane is called up, you begin at the very top of the screen. This area is off-limits to Richthofen's forces due to their limited flight ceilings. However, once you go down into their midst, you too are sealed off from this high-altitude bracket for the duration of the level.

\section*{Your Opponents}

Richthofen is employing three types of aircraft. Surveillance balloons patrol the areas they have been assigned to in accordance with random wind currents. These have been judged least important by the Air Force ( 50 points each). The remainder of the enemy forces consists of two types of aircraft: the main attack force, consisting of blue-green planes which always fly west, and the equally important red spy craft. Both types are worth 75 points each.

Some strategies and tips have been given to you by Air Force command. Although your aircraft can dodge mountains and the like without any danger, a number of civilian residences are scattered throughout the combat area. These present a very definite threat to navigation. You can neither fly nor fire through them. Furthermore, the explosions of the enemy craft are deadly to you.

\section*{Air Force Briefing}

The Air Force has also given you a short list of pointers for fighting the enemy. You will find that balloons are often extremely difficult to hit. This problem may be at least partially remedied by the use of the rapid-fire aspect of your controller. Holding down the fire button will cause your machine gun to fire rapidly after a slight initial delay. At times you may find yourself flying on and on without encountering any enemy craft. Often the problem is that the few surviving enemy fighter planes are going in the same direction as yourself. In such cases, simply turn and wait for them. To determine how far you are from the end of a level, consult the table below.

One final item is of some importance to you as a fighter pilot. The first planes sent out to you were of undeniably high quality and workmanship. The components were all painstakingly handformed, and the result was an airplane that could achieve an unusually high speed-enough, in fact, to overtake even the enemy fighter pilots. But as the production of these airplanes increased, the quality declined. Thus as you continue to play, you will find that your planes lose efficiency, until after a number of levels your top speed is barely that of the enemy planes.

Several keyboard controls have been included in the program. Pressing f7 causes all game action and sound to stop until the key is pressed again or the fire button pushed. RUN/ STOP has the same effect. F8 ends the program, leaving your country to Richthofen's mercy. F3 turns the sound of your engines on and off, but leaves the noise of shooting and explosions as always. F1 functions as a reset key, checking for a high score then returning you to the initial display.

A variety of melodies has been included in the program. All of them may be skipped by pressing the fire button on your joystick.

\section*{Levels of Play}
\begin{tabular}{|c|c|c|}
\hline Play & Number & Accumulated \\
\hline Level & of Enemy & Score \\
\hline 1 & 12 & 650 \\
\hline 2 & 16 & 1650 \\
\hline 3 & 20 & 2900 \\
\hline 4 & 24 & 4400 \\

\title{
Zuider Zee
}

Marc Sugiyama

Your mission is to save your village from flooding. This BASIC and machine language game will provide hours of fun. Requires the use of the MLX program.

Your village in Holland is built on land reclaimed from the ocean. High dikes keep the cold waters of the North Sea from flooding your land. But word has come that a terrible storm is approaching. Heavy rains and giant waves will undoubtedly break down sections of the dikes, flooding parts, perhaps all, of your land.

But you are prepared. You and your fellow Dutchmen have been battling the sea for centuries. In the old days, bucket brigades and sandbaggers would have fought the storm, and many lives might have been lost. Times have changed. Helicopters will rescue all the people whose homes are flooded, and as for repairing damage to the dikes and pumping out the water, that can all be done by one person. You.

\section*{You Are the Dikemaster}

As dikemaster, you are responsible for repairing the dikes and pumping out the floodwaters.

You have a truck with the latest landfill equipment, so that all you have to do is back it into place where you want to repair a broken dike. The truck does the rest.

You also have four pumps. When a dike has been repaired, you then have to pick up one of the pumps and put it in place on the dike. Then you set it up to pump water from the flooded fields and dump it back into the ocean. But be careful. If you set the pump wrong, it can pump water from the ocean and pour it onto land, making the flood worse than ever.

When you have successfully repaired all the dikes and pumped out all the water, you can't relax. You immediately get a promotion, and have to do the same for another village, where the storm is even worse.

And if you ever get so far behind that all your land is flooded
at the same time-well, you can certainly understand why your fellow villagers will start looking for a new dikemaster.

\section*{How to Play}

At the beginning of the game, you will be asked to choose a starting level. Until you get the hang of driving the truck and setting up the pumps, you'd probably better start at level 1, in which the storm is pretty mild and new gaps don't open up so often. Later, though, you can try higher levels.

The village. At the beginning of the game, the screen is filled with plowed fields, trees, and houses. The dikes are built, with the dikemaster's depot in the middle. Then the sea covers all the land outside the dikes. Finally, several breaks open in the dikes, and sections of the village lands are flooded. It's time for you to get to work!

Scoring. Scoring depends on several factors: how much land is covered with water; what level you are playing at; and how long you can keep the storm from entirely flooding the village.

Moving the truck. You drive your truck along the tops of the dikes by using the joystick. The dikes are slightly wider than the truck, so you can maneuver a little from side to side. You can't accidentally drive the truck off the dike.

Repairing the dike. Drive the truck to a break in the dike. You will want to dump a load of dirt into the break, to block it. Hold down the joystick button. This puts the truck in reverse. When you move the joystick, the truck will back up, moving the opposite direction from the direction in which you moved the joystick.

As long as you keep pressing the button and moving the joystick, the truck will keep backing up. When it reaches the edge of the dike, it stops and dumps a load of dirt off the edge of the dike. This creates a new section of dike. If you steered the truck correctly, the new section will repair the break in the dike. If not, you'll just have an extra load of dirt that doesn't connect with anything.

Your truck constantly scoops up more dirt as you drive from place to place-you will never run out of material to repair the dike.

Pumping out the water. Once a flooded area is completely surrounded by the dike, with no breaks, you can begin pumping. First, you must go and pick up a pump. At the beginning of the game, all four pumps are just outside the depot. Drive on top of

Machine Language Games
the pumps, push the joystick button, and your truck will automatically pick up a pump. Then drive to the edge of the flooded field you want to drain.

You will need to place the pump on the dike between the flooded field and the place where you want the water to be dumped. Usually you will want the water to be dumped in the ocean, but sometimes you will dump from one flooded field to another, or even from a flooded field to a field with no water on it.

You place the pump by holding down the joystick button and
game will stop, and the new village will be drawn on the screen. You will be at a harder level of play, which means that breaks will occur more often, and more land will be flooded at the beginning of play. However, you will also get more points at the higher levels.

\section*{Strategy Tips}

At lower levels of play, it is possible to repair all the dikes and completely pump out all the water. At higher levels, however, the storm is too intense, and dikes break too often. Here the best strategy is to choose four relatively small enclosures, set a pump on each, and then spend the rest of your time repairing breaks in the dikes as often as possible. The pumps will function whenever the field they are pumping is completely enclosed by dike walls. Since the game ends as soon as all the fields are completely flooded, it's better to keep one area dry, sacrificing the others, than to overextend yourself.

You can also take advantage of the fact that your truck will create a dike section wherever you want it. It is possible to build whole new dikes and create new fields. It is also possible to divide a large field into several smaller ones by building new dikes across it. This is particularly helpful at higher levels, when the dike breaks so often that you can't keep a large field completely enclosed long enough for it to be pumped dry.

\section*{Typing in the Program}

Most of the program is written in BASIC, but certain key routines are written in machine language and must be entered and SAVEd using the Machine Language Editor (MLX) found at the beginning of this chapter.

The MLX is a program that checks your DATA statements as you enter them and prevents you from entering the data incorrectly. Several other games in this chapter and programs in other COMPUTE! books for the Commodore 64 use the MLX program, so if you type it in once and SAVE it, you will use it again and again to enter error-free machine language programs.

The first step is to enter and SAVE the machine language routines using MLX. The MLX will ask you for two numbers.
Answer the prompts as follows:
Starting address: 49152
Ending address: 52040
Then start entering the data using the instructions given with the MLX program.

The next step is to type in and SAVE the BASIC program. The best way to save the two parts of this program is to save the machine language on a tape first and then save the BASIC part immediately after the machine language program.

\section*{Loading the Program}

Once you have both parts of the program SAVEd, you are ready to LOAD the program. First LOAD the machine language as follows:

From disk: LOAD"fn",8,1
From tape: LOAD \({ }^{\prime \prime \prime \prime}, 1,1\)
where fn is the filename.
Type NEW and LOAD the BASIC part as you would any other BASIC program. To begin play, type RUN and the game will begin.

Beginner's Guide to Typing in Programs

\section*{What is a Program?}

A computer cannot perform any task by itself. Like a car without gas, a computer has potential, but without a program, it isn't going anywhere. Most of the programs in this book are written in a computer language called BASIC. BASIC is easy to learn and is built into all Commodore 64s.

\section*{BASIC Programs}

Computers can be picky. Unlike the English language, which is full of ambiguities, BASIC usually has only one right way of stating something. Every letter, character, or number is significant. A common mistake is substituting a letter such as \(O\) for the numeral 0 , a lowercase 1 for the numeral 1 , or an uppercase \(B\) for the numeral 8. Also, you must enter all punctuation such as colons and commas just as they appear in the book. Spacing can be important. To be safe, type in the listings exactly as they appear.

\section*{Braces and Special Characters}

The exception to this typing rule is when you see the braces, such as \{DOWN\}. Anything within a set of braces is a special character or characters that cannot easily be listed on a printer. When you come across such a special statement, refer to "How To Type In Programs."

\section*{About DATA Statements}

Some programs contain a section or sections of DATA statements. These lines provide information needed by the program. Some DATA statements contain actual programs (called machine language); others contain graphics codes. These lines are especially sensitive to errors.

If a single number in any one DATA statement is mistyped, your machine could lock up, or crash. The keyboard and STOP key may seem dead, and the screen may go blank. Don't panicno damage is done. To regain control, you have to turn off your computer, then turn it back on. This will erase whatever program was in memory, so always SAVE a copy of your program before you RUN it. If your computer crashes, you can LOAD the program and look for your mistake.

Sometimes a mistyped DATA statement will cause an error message when the program is RUN. The error message may refer to the program line that READs the data. The error is still in the DATA statements, though.

\section*{Get to Know Your Machine}

You should familiarize yourself with your computer before attempting to type in a program. Learn the statements you use to store and retrieve programs from tape or disk. You'll want to save a copy of your program, so that you won't have to type it in every time you want to use it. Learn to use your machine's editing functions. How do you change a line if you made a mistake? You can always retype the line, but you at least need to know how to backspace. Do you know how to enter inverse video, lowercase, and control characters? It's all explained in your computer's manuals.

\section*{A Quick Review}
1) Type in the program a line at a time, in order. Press RETURN at the end of each line. Use backspace or the back arrow to correct mistakes.
2) Check the line you've typed against the line in the book. You can check the entire program again if you get an error when you RUN the program.
3) Make sure you've entered statements in braces as the appropriate control key (see "How To Type In Programs" elsewhere in the book).

\title{
How to Type In Programs
}

\section*{B}

\section*{How to Type In Programs}

Many of the programs which are listed in this book contain special control characters (cursor control, color keys, reverse video, etc.). To make it easy to know exactly what to type when entering one of these programs into your computer, we have established the following listing conventions.

Generally, any Commodore 64 program listings will contain words in braces which spell out any special characters: \{DOWN\} would mean to press the cursor down key. \{5 SPACES\} would mean to press the space bar five times.

To indicate that a key should be shifted (hold down the SHIFT key while pressing the other key), the key would be underlined in our listings. For example, \(\underline{S}\) would mean to type the S key while holding the shift key. This would appear on your screen as a heart symbol. If you find an underlined key enclosed in braces (e.g., \(\{10\) N\}), you should type the key as many times as indicated (in our example, you would enter ten shifted N 's).

If a key is enclosed in special brackets, \(\mathbb{Z \exists}\), you should hold down the Commodore key while pressing the key inside the special brackets. (The Commodore key is the key in the lower-left corner of the keyboard.) Again, if the key is preceded by a number, you should press the key as many times as necessary.

Rarely, you'll see a solitary letter of the alphabet enclosed in braces. These characters can be entered on the Commodore 64 by holding down the CTRL key while typing the letter in the braces. For example, \(\{\mathrm{A}\}\) would indicate that you should press CTRL-A.

About the quote mode: you know that you can move the cursor around the screen with the CRSR keys. Sometimes a programmer will want to move the cursor under program control. That's why you see all the \{LEFT\}'s, \{HOME\}'s, and \{BLU\}'s in our programs. The only way the computer can tell the difference between direct and programmed cursor control is the quote mode.

Once you press the quote (the double quote, SHIFT-2), you are in the quote mode. If you type something and then try to change it by moving the cursor left, you'll only get a bunch of reverse-video lines. These are the symbols for cursor left. The only editing key that isn't programmable is the DEL key; you can still use DEL to back up and edit the line. Once you type another quote, you are out of quote mode.

You also go into quote mode when you INSerT spaces into a line. In any case, the easiest way to get out of quote mode is to just press RETURN. You'll then be out of quote mode and you can cursor up to the mistyped line and fix it.

Use the following table when entering cursor and color control keys:
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline When You Read: & \multicolumn{2}{|l|}{Press:} & \multirow[t]{2}{*}{\begin{tabular}{l}
See: \\
曲需
\end{tabular}} & \multirow[t]{2}{*}{When You Read: \{GRN \}} & \multicolumn{2}{|l|}{Press:} \\
\hline \{ CLEAR \} & SHIFT & CLR/HOME & & & CTRL & 6 \\
\hline \{ HOME \} & & CLR/HOME & \(\cdots\) & \{BLU\} & CTRL & 7 \\
\hline \{UP \} & SHIFT & 4 CRSR & 48 & \{YEL\} & CTRL & 8 \\
\hline \{DOWN \} & & PCRSR & 4 & \{ Fl \} & \(f 1\) & \\
\hline \{LEFT\} & SHIFT & CRSR - & & \{ F2 \} & \(f 2\) & \\
\hline \{RIGHT \} & & CRSR & - & \{F3\} & \(f 3\) & \\
\hline \{RVS \} & CTRL & 9 & \% & \{F4\} & 44 & \\
\hline \{OFF\} & CTRL & 0 & & \{F5\} & \(f 5\) & \\
\hline \{BLK \} & CTRL & 1 & & \{F6\} & \(f 6\) & \\
\hline \{WHT \} & CTRL & 2 & E & \{F7 \} & \(f 7\) & \\

\hline \{PUR\} & CTRL & 5 &  & \[
\uparrow
\] & SHIFT & 9 \\
\hline
\end{tabular}

\title{
Maze Generator
}

Charles Bond Translated to machine language by Gary E. Marsa and for the 64 by Gregg Peele.

This program can be the basis for many excellent games.
Here's a remarkably short algorithm which produces random mazes on your TV screen.

To understand how it works, refer to the flowchart and Program 1. The following explanation should clarify the details.

\section*{The Background Field}

The algorithm operates on a background field which must be generated on the screen prior to line number 210 in Program 1. The field must consist of an odd number of horizontal rows, each containing an odd number of cells: a rectangular array. It's convenient to think of the field as a two-dimensional array with the upper-left corner having coordinates \(X=0\) and \(Y=0\), where \(X\) is the horizontal direction and \(Y\) is vertical. No coordinates are used to identify absolute locations by the program, but the concept is useful in configuring the field.

Given that the upper-left cell of the field has coordinates 0,0 , then the terminal coordinates both horizontally and vertically must be even numbers. In addition, the background field must be surrounded on all sides by memory cells whose contents are different from the number used to identify the field. That is, if the field consists of reversed (or inverse video) spaces, then the number corresponding to that character must not be visually adjacent to the field.

This could happen inadvertently if the screen RAM and system ROM have contiguous addresses. A sufficient precaution is to avoid covering the entire screen with field. Leave at least one space at the beginning or end of each line and, in general, leave the uppermost and lowermost lines on the screen blank.

\section*{The Maze Generator}

The creation of the maze begins by placing a special marker in a suitable starting square. The program here always begins at the square just inside the upper-left cell of the previously drawn field. (Note that with our coordinate scheme this would be cell 1,1.) Any cell with odd-numbered coordinates would work, however, as long as it is internal to the field.

Next, a random direction is chosen by invoking the random number generator in your machine and producing an integer from 0 to 3 . This integer, with the aid of a short table, determines a direction and a corresponding cell just two steps away from the current cell. This new cell is examined (PEEKed) to see if it is part of the field. If it is, the direction integer is put there as a marker, and the barrier between it and the current cell is erased.

In addition, the pointer to the current cell is moved to point to the new one. This process is repeated until the new cell fails the test; that is, it is not a field cell. When this happens, the direction vector is rotated 90 degrees and the test is repeated. Thus, the path carved out of the field will continue until a dead end is reached.

A dead end, incidentally, could occur in as few as five steps. When it does occur, we can make use of the markers which were dropped along the way Hansel and Gretel style. These can be checked to determine which direction we came from, so that we can back up and look for untrodden paths. So long as none can be found, the program will back up, one step at a time, erasing the markers as it goes. When a new direction can be taken, the pointer is set off in that direction, and the process continues as before.

Ultimately, the pointer will return to the start, a condition which is detected by the recovery of the special starting (now "ending") marker. This cell is then blanked and the program is done, leaving the pointer as it was at the start.

\section*{The Program}

The direction table set up in lines 100 and 110 converts an integer to an address offset. In this case ( 40 -column screen), we wish to step two cells to the right, up, left, or down.

Line 120 contains the variable SC, which is the memory address of the start of screen RAM. Lines 130-160 establish the background field on the screen.

The rest of the program draws the maze, as previously
explained. Line 310 is simply a convenient stopping point which prevents the screen from scrolling.

It may not be immediately obvious that this algorithm always produces a maze with only one nontrivial path between any two points, or that the maze will always be completely filled, but this can be proved. While the proofs will not be provided here, math buffs may find it interesting that for a maze of any size there will be exactly:
\[
\frac{(\mathrm{H}-1)(\mathrm{V}-1)}{2}-1 \text { empty cells in the completed maze, }
\]
where H is the number of cells in each field row and V is the number of rows.

An interesting feature of this algorithm is that it works equally well in certain types of nonrectangular fields. U-shaped fields or fields with holes in them are quite suitable-as long as certain restrictions are observed. Just make sure that the coordinates of the upper-left and lower-right cells of any cut-out area are pairs of odd numbers. Also, if there is a single row of field cells between any cut-out areas and the outside of the original field, it may be removed.

\section*{Machine Language Mazes}

Program 2 is a machine language translation of Program 1. It is in the form of a BASIC loader. It can be inserted into any BASIC program just as Program 1.

Program 3 is the assembly listing of the machine language routine found in Program 2.

\section*{The Mouse}

The subroutine on lines 1000 to 1020 of Program 1 produces an artificial mouse which roams the maze endlessly. The mouse adheres to a "left-hand rule" when a choice of directions is possible. That is, when it is confronted with a branch-point, it will move off to the left, if possible. Otherwise, it will go forward. When no choice is available, it will turn around. These lines are unnecessary for the creation of the maze and may be deleted.
Programs 2 and 3 do not contain the mouse.

\title{
Do You Want to Write Your Own Games?
}

Orson Scott Card

I remember when videogames first reached my town back in the early seventies. A friend and I dropped a few quarters into a Pong machine and had a great time. But all in all, we preferred playing Ping-Pong on a real table.

But then, in a theater lobby, we met Breakout, and it changed my life. I became a dedicated videogamer from that time forward.

Because there on a TV screen-not even a color screen, then, just black-and-white with colored plastic strips-the videogame was offering an experience that I couldn't get anywhere else. The speed and the concept both were something entirely new.

Everybody knows where it went from there. Turn Breakout's paddle into a spaceship, give the bricks a different shape, and let them march down the screen at you, and you have Space Invaders. Turn Breakout's paddle into a race car and let it drive over dots instead of bricks, and you have the earliest gobble games. The shoot-outs and gobble games, the climbing games and the simula-tions-they have all become more sophisticated.

Now, on your own TV at home, you can have the little airplanes of "Richthofen's Revenge" flying around. And you typed the game into your computer yourself.

\section*{Getting Behind the Games}

If you're like me, however, playing was never really enough. Right from the beginning, I wondered how it was done. I knew nothing about computers then-like many people, I thought computers were for people who were good in math or interested in engineering, and I was definitely neither. But for the first time I wanted to have whatever abilities it took to program computers. Because I wanted to make my own games.

I wanted to create a game where I could handle old-time sailing ships through currents and winds to explore different islands and conduct sea battles.

I wanted a game where I could build cities and design traffic flow patterns, create the image of a city's life.

I wanted to have the power of a computer to create whatever world I wanted, and whatever game I wanted to play within that world.

But I knew it would never happen. I wasn't good in math or interested in engineering, and to people like me computers would never be anything but big black boxes.

\section*{Unlocking the Little Black Box}

The big black boxes have changed, haven't they? You can treat your 64 as a black box, if you want-plug in a game on a ROM cartridge and away you go. But for most games, you still need to type things like LOAD and RUN. And for the games in this book, you need to type in entire programs.

And if it hasn't occurred to you before, it certainly should be plain now. You have the equipment to program all those games you have always wished you could play. Your Commodore 64 can do almost everything the videogames in the arcade can do.

Best of all, though, it can do things that have never been done before. It can display worlds that you create, and carry out actions that you designed.

And as for the myth that programmers have to be good in math or engineering-you don't believe that anymore, do you? My wife still has to balance the checkbook for me and I can't tell a circuit diagram from a plate of vermicelli, but I have written games that actually work, using BASIC and machine language both. And like those old-time ads ("My Friends Laughed When I Sat Down At The Piano"), I assure you that if I can do it, anybody can.

\section*{How to Learn How to Program Games}

Unfortunately, you won't find a night school class in videogame programming. Colleges and high schools tend to teach programming with a business or mathematical slant. They rarely teach much about the graphics and sound techniques at the heart of game programming.

So the best way to learn programming is to find a friend who's an expert videogame programmer and get him to teach
you, step by step, how to solve the problems you run into trying to program your first game. Because you can only learn to program by programming, and having an expert (and patient) friend gets you through the rough places.

The second best way is books.
There are books that teach you BASIC programming for the Commodore 64, reference books that give you valuable information about memory locations and special techniques, books that teach machine language programming for the 6510 that runs your 64, and even a book called Creating Arcade Games on the Commodore 64 , which sounds like exactly the book you want.
(Before I give you my full list of recommended reading, I'd better explain something. This list will include mostly books published by COMPUTE! Books, which is the publisher of COMPUTE!'s First Book of Commodore 64 Games. However, this is not merely shameless self-promotion. Wherever I knew of a valuable teaching or reference book by another publisher, I have listed it. But the Commodore 64 is such a new computer that at the time of this writing, most publishers don't have their Commodore 64 books out yet. In fact, many of the books on my list haven't been published yet, either. But because I'm an editor at COMPUTE! Books, I know all about our books that are at the printer or in production or still coming, a chapter at a time, from authors in California, Michigan, Utah, Virginia, Pennsylvania, and New Jersey. Therefore, I can include those books on the list and promise you that they'll help you learn programming. But I can't tell you about forthcoming books by other publishers because, unfortunately, in the world of publishing we don't always tell each other what we have planned. By the time you read this, there may be a hundred other books that can help you; this list will only tell you about the ones I know.)

In the following list, an asterisk (*) marks the books that are useful only if you are planning to use machine language.

BASIC Programming. If you're new at programming, here are some books that can help supplement the manuals published by Commodore.

Camp, David. Creating Arcade Games on the Commodore 64. Greensboro, North Carolina: COMPUTE! Books.

Chamberlain, Craig. All About the Commodore 64.2 vols. COMPUTE! Books.

Heilborn, John and Ron Talbott. Your Commodore 64: A Guide to the Commodore 64 Computer. Berkeley, California: Osborne/ McGraw-Hill.

COMPUTE!'s First Book of Commodore 64.
Commodore 64 Programmer's Reference Guide. West Chester, Pennsylvania: Commodore Business Machines, Inc.

Graphics and Sound Techniques. Once you've mastered the basics of BASIC, you can get into the fascinating techniques of moving shapes and colors on the TV screen and creating sounds from the TV speaker. This is an area where the Commodore 64 is different from every other computer, even its little brother, the VIC-20.

Heilborn, John. COMPUTE!'s Reference Guide to Commodore 64 Graphics.

Heilborn, John. COMPUTE!'s Reference Guide to Commodore 64 Sound.

COMPUTE!'s First Book of Commodore 64 Sound and Graphics.
Reference Books. These are books that give you detailed information about features and key memory locations of the Commodore 64. Many of these features are only usable in machine language, but others are valuable to BASIC programmers as well.
*Heeb, Dan. The Commodore 64 Tool Kit: Kernal Routines. COMPUTE! Books.
*Heeb, Dan. The BASIC Tool Kit: Commodore 64 and VIC-20. COMPUTE! Books.

Leemon, Sheldon. Mapping the Commodore 64. COMPUTE! Books.

Learning Machine Language. These are books that help you learn how to put real speed and complex but smooth animation into your videogames.

Fernandez, Judi N., Donna N. Tabler, and Ruth Ashley. 6502 Assembly Language Programming. New York: John Wiley and Sons.

Leventhal, Lance A., and Winthrop Saville. 6502 Assembly Language Subroutines. Osborne/McGraw-Hill.

Mansfield, Richard. Machine Language for Beginners. COMPUTE! Books.

Zaks, Rodnay. Programming the 6502. Berkeley, California: Sybex.

\section*{COMPUTEI'S First Book of Commodore64 Games}

COMPUTE's First Book of Commodore 64 Games includes 19 games complete and ready to type in, so no programming knowledge is necessary.
- Save the Snake in "Snake Escape"
- Mine in "Oil Tycoon"
- Attack the sky skimmer in "The Hawkmen of Dindrin"
- Shoot at the invading spaceships in "Laser Gunner"

Here are 15 of the best games from COMPUTE! Magazine and COMPUTE!'s Gazette, plus four never-before-published games, including the arcade-speed "Richthofen's Revenge," "Spike," and "Zuider Zee".

"Diamond Drop"

"Richthofen's Revenge"

"Zuider Zee"

"Mystery Spell"```
